Received 19 June 2017; editorial decision 28 August 2017; accepted 2 September 2017; online publish-ahead-of-print 10 October 2017

We are in the midst of a digital revolution in health care, although the application of new and useful technology in routine clinical practice is variable. The Characterizing Atrial fibrillation by Translating its Causes into Health Modifiers in the Elderly (CATCH ME) Consortium, in collaboration with the European Society of Cardiology (ESC), has funded the creation of two applications (apps) in atrial fibrillation (AF) for use in smartphones and tablets. The patient app aims to enhance patient education, improve communication between patients and health care professionals, and encourage active patient involvement in the management of their condition. The health care professional app is designed as an interactive management tool incorporating the new ESC Practice Guidelines on AF and supported by the European Heart Rhythm Association (EHRA), with the aim of improving best practice approaches for the care of patients with AF. Both stand-alone apps are now freely available for Android and iOS devices though the Google Play, Amazon, and Apple stores. In this article, we outline the rationale for the design and implementation of these apps. Our objective is to demonstrate the value of integrating novel digital technology into clinical practice, with the potential for patient engagement, optimization of pharmacological and interventional therapy in AF, and ultimately to improve patient outcomes.

Keywords Atrial fibrillation • Smartphone • Mobile • Application • App • Education • Management • Treatment • Guidelines

Introduction

Smartphones, tablet computers, and their applications (apps) have become ubiquitous in modern life all across the world. In Europe and North America, approximately two-thirds of the population own mobile devices, with year-on-year increases. Their role in our lives has continually changed, and for many people, smartphones and tablets are the primary method for communication and accessing online...
What’s new?

- The 2016 European Society of Cardiology (ESC) Guidelines on atrial fibrillation (AF) recommend patient-centred care and an integrated, multidisciplinary treatment approach.
- Smartphone and tablet apps can provide education, encourage behaviour change, and increase treatment adherence in patients as well as deliver interactive treatment algorithms to aid clinicians.
- The patient app aims to enhance patient education on AF, self-management, and shared decision-making.
- The health care professional app is designed around the 2016 ESC Guidelines on AF to simplify the choice of treatment and optimize guideline adherence.

Evidence from other health care apps

The impact of health-related apps has been studied in numerous randomized controlled trials. During our design phase, we performed a keyword search of PubMed and Google Scholar to identify apps with published health outcomes (April 2016; search terms/mobile and randomized) and summarize some key trials here. An app providing cognitive behavioural therapy skills demonstrated reduced symptoms of depression and less work absence compared with those randomized to website support ($n = 300$). In 597 adults with back pain, a mobile app successfully encouraged self-management skills, leading to a reduction in back pain at 4 months.

Rationale

The patient and health care professional apps for AF were developed to disseminate the new 2016 ESC AF Guidelines through different formats to reach a wide and expanding audience. Our approach had three main foundations that are discussed in detail below:

(i) Apps in other health care settings have had a positive impact on patient behaviour and clinical outcomes; (ii) digital learning in the context of educational theory affords a new pathway of providing supportive patient education; and (iii) education of health care professionals and encouraging guideline-adherent care can contribute to enhanced professional standards and improved management of patients with AF.
levels of use within education remains modest. There are also important limitations that can impede digital learning, such as language, culture, and baseline knowledge, as well as app functionality and readability.

So what are the theoretical implications for app development to assist patients with AF? Figure 2 adapt Salons five-stage model of online learning to illustrate the key points of a structured developmental process. These can lead to patient enablement (provision of appropriate context for new knowledge and skills) and, hence, supported and successful learning (as described by Vygotskys Zone of Development). Reflecting on the learning classification described by Bloom, users start to understand new concepts and apply knowledge to their own circumstances. One of the aims of our app is to allow independent patient evaluation of treatment options, enabling an informed choice and partnership-in-care between patients and their health care providers. Such a model has the potential to encourage satisfaction with treatment, increase self-management, reduce cost, and improve patient well-being.

Context of professional standards

Physician education

Professional standards frameworks across Europe highlight the importance of ongoing education. In this context, mobile applications are an important part of integrating and internalizing knowledge as well as transmitting this learning to others. The general direction of technology suggests that mobile applications will become an increasingly important method to improve and maintain professional standards in health care.

Physician interaction with patients

The active participation of patients in health care consultations and development of patient autonomy is a principle common to professional standards across the world. This includes the Physician Charter, adopted by the European Federation of Internal Medicine, the American Board of Internal Medicine, and the American College of Physicians, as well as standards of the UK General Medical Council. The CanMEDS code of the Royal College of Physicians and Surgeons of Canada puts a responsibility on physicians to facilitate patient learning, not only by educating patients but also by promoting health literacy for the purposes of establishing rapport and trust, formulating a diagnosis, delivering information, striving for mutual understanding, and facilitating a shared plan of care.

Similarly, the Core Curriculum for General Cardiologists of the ESC and the Core Curriculum for Nurses of the ESC Council for Cardiovascular Nursing and Allied Professions recognize the importance of patient education in all areas of cardiac care.

Design

App design was led by a core group (see Supplementary material online, Appendix 1) comprising of representatives from the Characterizing Atrial fibrillation by Translating its Causes into Health Modifiers in the Elderly (CATCH ME) Consortium, the ESC Guidelines Task Force on AF, and the European Heart Rhythm Association (EHRA). Borm Bruckmeier Publishing (Germany) was commissioned to produce the apps. The main components and objectives of the app development programme are displayed in Figure 3.

In brief, we developed the apps in tandem with the writing of the 2016 ESC Guidelines on AF while maintaining the confidentiality of the guidelines. The Task Force writing the guidelines were instrumental in defining the content of the apps. The guideline flowcharts for different sections of AF management determined the design of the apps. This process began in October 2014, an outline of the app functionalities was completed in October 2015, and the final guideline structure was incorporated into the Apps Software Requirements Specification by February 2016. Model View Presenter Framework (Android) and Model View Controller (iOS) were used, with the overall product based on Client Server Architecture. The apps were publicly released at the ESC Congress in Barcelona (August 2017).

As the Healthcare Professional app determines patient treatment, a CE (Conformit Europene) certification application has been submitted to conform with European Commission Directives (Class Il medical device).

Patient app

The patient app provides education on AF, including sections describing the pathology, symptoms, prognosis, associated comorbidities, management strategies, and practical tips for self-care (Figure 4A). Information was derived from existing patient documentation developed by the British Heart Foundation (https://www.bhf.org.uk/), the German National Network of Competence in Atrial Fibrillation (AFNET: http://www.kompetenznetz-vorhofflimmern.de/), and a patient booklet on AF developed in the Netherlands. The text was then edited by a team of patient representatives with AF (funded through a UK National Institute of Health Research grant on improving patient outcomes in AF). The patient app will also present information on individual stroke risk and provide a personal health record and symptom diary. Patients are asked to fill in sections about relevant previous health issues, which can facilitate consultation when shared with their health care professional(s).

Healthcare Professional app

The Healthcare Professional app is a more complex tool, allowing both conventional viewing of guideline text and recommendations and interactive treatment algorithms (Figure 4B). The app is also
Figure 2 Learning framework applied to the AF apps. Process and facilitation of online learning associated with smartphone applications for AF. Adapted from the five-stage model as proposed by Salmon (2013). AF, atrial fibrillation; HCP, health care professional.

Figure 3 Components and objectives of the app development programme. AF, atrial fibrillation; ESC, European Society of Cardiology.
designed to improve consultation efficiency, with the provision of a patient register, pre-filled with data supplied by the patient. A tablet version of the app will also be available, allowing overview of multiple patients (e.g. in an outpatient clinic setting). Users are able to launch the AF Treatment Manager directly through the existing ESC Pocket Guidelines app, also available free of charge for iOS and Android devices through their respective stores.

**Figure 4** Screenshots of the patient app (A) and the health care professional app (B). Both apps available free of charge for Android and iOS through the Google Play, Amazon, and Apple stores. The standalone AF treatment manager can also be accessed through the ESC Pocket Guidelines app (AF section). All names displayed in the figure are fictitious.

**Patient to doctor communication, security, and privacy**

A key feature of the apps is communication between consenting patients and their health care professional(s). Patients will be able to securely share their data through a cloud server, permitting health care professionals to import relevant information into the Healthcare Professional app (such as symptoms, stroke risk factors, and...
medications). The patient can disable this access at any time. All shared information is encrypted and password protected. Reciprocally, the health care professional can also share collated information with the patient, in the form of an automated email.

**Potential for observational research**

For patients who specifically consent to the use of data for research purposes, anonymized data will be saved for future exploration of symptomatology, treatment patterns, and guideline adherence. This is an unparalleled capability, allowing us to collate information on patients with AF across all communities, including primary practice and hospital clinics. Understanding the barriers to effective guideline implementation will help to improve future guidelines on AF and make them more relevant to patient care.

**Evaluation**

Evaluation of the apps is essential to determine their ability to provide knowledge to patients and health care professionals and their impact on guideline adherence. This is an ongoing process, and feedback will drive the further development of these tools.

The process of initial testing and evaluation was as follows:

1. Appraisal by members of the ESC AF Guidelines Task Force to ensure that content for both patient and health care apps followed guideline recommendations.
2. In-house testing of individual components by the app development team, including at least fortnightly confidential teleconferencing updates during the finalization of the 2016 ESC AF Guidelines.
3. Initial evaluation was centred around interface design, technology, and acceptability, using published scales that help evaluate health care smartphone applications (see Supplementary material online, Appendix 2).
4. Discussions and protocol development for patient data protection, data storage, and security.
5. Patient-facing materials (educational text and images) were designed and reviewed by a patient involvement team and representatives of the British Heart Foundation.
6. Testing of each app in entirety by the app development team to identify programming errors and inconsistencies.
7. Confidential testing and design enhancement by the wider ESC AF Guidelines Task Force, members of the CATCH ME consortium and EHRA to improve app functionality.
8. Beta-testing using self-contained devices within user cohorts to ensure acceptable language, ease of use, and clinical utility. The apps were tested by a group of CATCH ME investigators and junior and senior clinicians at the CATCH ME clinical centres on three occasions throughout 2016. Further testing regarding content and usability was carried out during the AFNET/EHRA Consensus Conference (January 2017) by AF clinicians and specialists.
9. Updates following beta-testing and finalization of app design. Beta-testing was performed by 67 persons (iOS and Android, both patient and health care professional apps), with feedback leading to new test versions. In total, there were 50 test versions of the apps, with step-wise iterations leading to better functionality.

**Post-publication feedback**

As surveying users can often be biased, the apps will include an anonymous feedback option for comment on features that work or do not work well. Although web-based surveys also suffer from sampling biases, they do allow more self-disclosure and are likely to be a more useful tool for evaluation and subsequent app modification.

**Discussion**

The development of smartphone and tablet apps for patients and health care professionals is an exciting opportunity to increase active patient involvement in the management of their AF, provide education to patients and health care professionals, and potentially improve clinical outcomes through the pursuit of guideline-adherent care. This approach is well suited to provide structured and integrated management of AF, as recommended in the 2016 ESC AF Guidelines.

As discussed above, there is a good rationale behind the development of apps in AF, including evidence from other health care applications showing improvement in patient management. The apps also provide a new method to support patient empowerment through education as well as easily accessible ‘on-the-job’ health care professional training. The ability of the apps to enhance learning is based on a number of educational theories that offer users not only knowledge from evidence-based guidelines but also the application and reinforcement of this information within a digital platform. The health care professional app also addresses a number of key professional standards for the development of good clinical practice with regard to continued professional development and establishing an integrated, patient-centred approach to care. The long-term management of chronic conditions like AF is likely to benefit from informed and autonomous patients, potentially leading to better outcomes through shared decision-making. Although patient information is now widely available through written and verbal information, there remains a lack of specific knowledge related to AF. Currently available education tools are almost entirely focused on anticoagulation therapy, and although of clear clinical importance, this may not match what patients want and need to know about AF in general. The huge advantage of our app-based tools is the dynamic nature of the technology, allowing us to add and modify features or information sources in response to user feedback and reflecting future updates of the ESC AF guidelines.

App-based interventions are a relatively new method of education in health care; however, there is a large body of evidence for online learning in the teaching profession. In a systematic review of 99 studies, face-to-face and online learning methods were examined in a variety of topics for undergraduate and postgraduate learners. Effect sizes were largest for the combination of face-to-face and online instruction compared with either separately, and online working was more efficient if directed or collaborative rather than independent student learning. To extrapolate to the use of medical apps, this reinforces the need for the patient app to be part of the clinical experience, underpinned by the standard educational approach from health care professionals. Similarly, the Healthcare Professional app should be used in the context of ongoing professional development to achieve improvements in clinical management. New innovations usually go through a peak and trough of usage (the so-called ‘hype cycle’), and the design group were therefore keen to ensure that the apps retain relevance and functionality over time by including the means for continual update and improvement. The rapid rate of change in
technology itself creates a number of issues related to access, ethical process, and privacy. However, as the general public move towards greater acceptance (and reliance) on mobile platforms, the medical community have an opportunity to use these advances to improve patient care.

Limitations
There are limitations to our approach, most notably that not all patients and health care professionals will have access to smartphones or tablets. However, recent data from the USA suggest that even in adults over the age of 65, internet use is increasing exponentially and that around 70% now own a mobile phone (although smartphones in this age group are still less common). The main barriers to smartphone use in older patients appears to be related to lack of perceived knowledge around the technology and visual impairment. Both of these issues were considered during the design phase of the apps, with the use of ‘patient-approved’ education materials, simple functionality, straightforward layout, and readable font size.

Finally, although digital forms of learning are increasing and may provide benefit, there is a tendency to overvalue the use of technology. Put simply, we should ensure that the time spent in learning and using a new resource is time and cost-efficient, with sustained value over any short-term (or gimmick) objectives. Our aim was to achieve good productivity of both the patient and health care professional apps, and for usage to increase over time, while accepting that our initial designs are likely to need ongoing improvements in response to the changing requirements of patients with AF and their health care providers.

Conclusions and clinical perspective
We have outlined the rationale for new smartphone and tablet applications for patients with AF and their health care professionals, reviewing the evidence for improving patient outcomes, enhancing professional standards, and supporting the use of digital learning. Our clinical aim is to increase patient engagement and guideline adherence with AF management, and, ultimately, improve patient well-being and long-term prognosis. The apps are freely available for Android and iOS devices.
