RANDOM DOUBLY STOCHASTIC MATRICES: THE CIRCULAR LAW

BY HOI H. NGUYEN
Ohio State University

Let $X$ be a matrix sampled uniformly from the set of doubly stochastic matrices of size $n \times n$. We show that the empirical spectral distribution of the normalized matrix $\sqrt{n}(X - \mathbb{E}X)$ converges almost surely to the circular law. This confirms a conjecture of Chatterjee, Diaconis and Sly.

1. Introduction. Let $M$ be a matrix of size $n \times n$, and let $\lambda_1, \ldots, \lambda_n$ be the eigenvalues of $M$. The empirical spectral distribution (ESD) $\mu_M$ of $M$ is defined as

$$
\mu_M := \frac{1}{n} \sum_{i \leq n} \delta_{\lambda_i}.
$$

We also define $\mu_{\text{cir}}$ as the uniform distribution over the unit disk

$$
\mu_{\text{cir}}(s, t) := \frac{1}{\pi} \text{mes}(|z| \leq 1; \Re(z) \leq s, \Im(z) \leq t).
$$

Given a random $n \times n$ matrix $M$, an important problem in random matrix theory is to study the limiting distribution of the empirical spectral distribution as $n$ tends to infinity. We consider one of the simplest random matrix ensembles, when the entries of $M$ are i.i.d. copies of the random variable $\xi$.

When $\xi$ is a standard complex Gaussian random variable, $M$ can be viewed as a random matrix drawn from the probability distribution $\mathbb{P}(dM) = \frac{1}{\pi^n} e^{-\text{tr}(MM^*)} dM$ on the set of complex $n \times n$ matrices. This is known as the complex Ginibre ensemble. Following Ginibre [14], one may compute the joint density of the eigenvalues of a random matrix $M$ drawn from the

following complex Ginibre ensemble: $(\lambda_1, \ldots, \lambda_n)$ has density

\[
p(z_1, \ldots, z_n) := \frac{n!}{\pi^n} \prod_{k=1}^{n} k! \exp\left(-\sum_{k=1}^{n} |z_k|^2\right) \prod_{1 \leq i < j \leq n} |z_i - z_j|^2
\]

(1.1)

on the set $|z_1| \leq \cdots \leq |z_n|$.

Mehta [24, 25] used the joint density function (1.1) to compute the limiting spectral measure of the complex Ginibre ensemble. In particular, he showed that if $M$ is drawn from the complex Ginibre ensemble, then $\mu_{(1/\sqrt{n})M}$ converges to the circular law $\mu_{cir}$. Edelman [11] verified the same limiting distribution for the real Ginibre ensemble.

For the general case, there is no formula for the joint distribution of the eigenvalues, and the problem appears much more difficult. The universality phenomenon in random matrix theory asserts that the spectral behavior of a random matrix does not depend on the distribution of the atom variable $\xi$ in the limit $n \to \infty$.

In the 1950s, Wigner [41] proved a version of the universality phenomenon for Hermitian random matrices. However, the random matrix ensemble described above is not Hermitian; in fact, many of the techniques used to deal with Hermitian random matrices do not apply to non-Hermitian matrices.

An important result was obtained by Girko [15, 16] who related the empirical spectral measure of non-Hermitian matrices to that of Hermitian matrices. Consider the Stieltjes transform $s_n$ of $\mu_{(1/\sqrt{n})M}$ given by

\[
s_n(z) := \frac{1}{n} \sum_{i=1}^{n} \frac{1}{(1/\sqrt{n})\lambda_i - z} = \int_{C} \frac{1}{x + \sqrt{-1}y - z} d\mu_{1/\sqrt{n}M}(x, y).
\]

Since $s_n$ is analytic everywhere except at the poles, the real part of $s_n$ determines the eigenvalues. We have

\[
\Re(s_n(z)) = \frac{1}{n} \sum_{i=1}^{n} \frac{(1/\sqrt{n})\Re(\lambda_i) - \Re(z)}{|(1/\sqrt{n})\lambda_i - z|^2}
\]

\[
= -\frac{1}{2n} \sum_{i=1}^{n} \frac{\partial}{\partial \Re(z)} \log \left| \frac{1}{\sqrt{n}} \lambda_i - z \right|^2
\]

(1.2)

\[
= -\frac{1}{2n} \frac{\partial}{\partial \Re(z)} \log \det \left( \frac{1}{\sqrt{n}} M - z I \right) \left( \frac{1}{\sqrt{n}} M - z I \right)^*,
\]

where $I$ denotes the identity matrix.

In other words, the task of studying the eigenvalues of the non-Hermitian matrix $\frac{1}{\sqrt{n}} M$ reduces to studying the eigenvalues of the Hermitian matrix $(\frac{1}{\sqrt{n}} M - z I)(\frac{1}{\sqrt{n}} M - z I)^*$. The difficulty now is that the log function has two poles, one at infinity and one at zero. The largest singular value can
easily be bounded by a polynomial in \( n \). The main difficulty is controlling the least singular value.

The first rigorous proof of the circular law for general distributions was by Bai \([1]\). He proved the result under a number of moment and smoothness assumptions on the atom variable \( \xi \). Important results were obtained more recently by Pan and Zhou \([29]\) and Götze and Tikhomirov \([17]\). Using a strong lower bound on the least singular value, Tao and Vu \([34]\) were able to prove the circular law under the assumption that \( E|\xi|^{2+\varepsilon} < \infty \), for some \( \varepsilon > 0 \). Recently, Tao and Vu (Appendix by Krishnapur) \([36]\) established the law assuming only that \( \xi \) has finite variance.

**Theorem 1.1** \([36]\). Assume that the entries of \( M \) are i.i.d. copies of a complex random variable of mean zero and variance one, then the ESD of the matrix \( \frac{1}{\sqrt{n}}M \) converges almost surely to the circular measure \( \mu_{\text{cir}} \).

In view of the universality phenomenon, it is important to study the ESD of random matrices with nonindependent entries. Probably one of the first results in this direction is due to Bordenave, Caputo and Chafai \([6]\) who proved the following.

**Theorem 1.2** \([6\), Theorem 1.3]. Let \( X \) be a random matrix of size \( n \times n \) whose entries are i.i.d. copies of a nonnegative continuous random variable with finite variance \( \sigma^2 \) and bounded density function. Then with probability one the ESD of the normalized matrix \( \sqrt{n}X \), where \( X = (\tilde{x}_{ij})_{1 \leq i,j \leq n} \) and \( \tilde{x}_{ij} := x_{ij}/(x_{i1} + \cdots + x_{in}) \), converges weakly to the circular measure \( \mu_{\text{cir}} \).

In particular, when \( x_{11} \) follows the exponential law of mean one, Theorem 1.2 establishes the circular law for the Dirichlet Markov ensemble (see also \([8]\)).

Related results with a linear assumption of independence include a result of Tao, who among other things proves the circular law for random zero-sum matrices.

**Theorem 1.3** \([33\), Theorem 1.13]. Let \( X \) be a random matrix of size \( n \times n \) whose entries are i.i.d. copies of a random variable of mean zero and variance one. Then the ESD of the normalized matrix \( \sqrt{n}X \), where \( X = (\tilde{x}_{ij})_{1 \leq i,j \leq n} \) and \( \tilde{x}_{ij} := x_{ij} - \frac{1}{n}(x_{i1} + \cdots + x_{in}) \), converges almost surely to the circular measure \( \mu_{\text{cir}} \).

With a slightly different assumption of dependence, Vu and the current author showed in \([28]\) the following.

**Theorem 1.4** \([28\), Theorem 1.2]. Let \( 0 < \varepsilon \leq 1 \) be a positive constant. Let \( M_n \) be a random \((-1,1)\) matrix of size \( n \times n \) whose rows are independent vectors of given row-sum \( s \) with some \( s \) satisfying \( |s| \leq (1 - \varepsilon)n \). Then
the ESD of the normalized matrix $\frac{1}{\sigma \sqrt{n}} M_n$, where $\sigma^2 = 1 - \left( \frac{s}{n} \right)^2$, converges almost surely to the distribution $\mu_{\text{cir}}$ as $n$ tends to $\infty$.

To some extent, the matrix model in Theorem 1.4 is a discrete version of the random Markov matrices considered in Theorem 1.2 where the entries are now restricted to $\pm 1/s$. However, it is probably more suitable to compare this model with that of random Bernoulli matrices. By Theorem 1.1, the ESD of a normalized random Bernoulli matrix obeys the circular law, and hence Theorem 1.4 serves as a local version of the law.

Although the entries of the matrices above are mildly correlated, the rows are still independent. Because of this, we can still adapt the existing approaches to bear with the problems. Our focus in this note is on a matrix model whose rows and columns are not independent.

**Theorem 1.5** (Circular law for random doubly stochastic matrices). Let $X$ be a matrix chosen uniformly from the set of doubly stochastic matrices. Then the ESD of the normalized matrix $\sqrt{\frac{1}{n}}(X - EX)$ converges almost surely to $\mu_{\text{cir}}$.

Little is known about the properties of random doubly stochastic matrices as it falls outside the scope of the usual techniques from random matrix theory. However, there have been recent breakthroughs by Barvinok and Hartigan; see, for instance, [3–5]. The Birkhoff polytope $M_n$, which is the set of doubly stochastic matrices of size $n \times n$, is the basic object in operation research because of its appearance as the feasible set for the assignment problem. Doubly stochastic matrices also serve as a natural model for priors in statistical analysis of Markov chains. There is a close connection between the Birkhoff polytope and $\text{MS}(n, c)$, the set of matrices of size $n \times n$ with nonnegative integer entries and all column sums and row sums equal $c$. These matrices are called magic squares, which are well known in enumerative combinatorics. We refer the reader to the work of Chatterjee, Diaconis and Sly [9] for further discussion.

There is a strong belief that random doubly stochastic matrices behave like i.i.d. random matrices. This intuition has been verified in [9] in many ways. Among other things, it has been shown that the normalized entry $nx_{11}$ converges in total variation to an exponential random variable of mean one. More generally, the authors of [9] showed that the normalized projection $nX_k$, where $X_k$ is the submatrix generated by the first $k$ rows and columns of $X$ with $k = O\left(\frac{\sqrt{n}}{\log n}\right)$, converges in total variation to the matrix of independent exponential random variables.

Regarding the spectral distribution of $X$, it has been shown by Chatterjee, Diaconis and Sly that the empirical distribution of the singular values of $\sqrt{n}(X - EX)$ obeys the quarter-circular law.
Theorem 1.6 ([9], Theorem 3). Let $0 \leq \sigma_1, \ldots, \sigma_n$ be the singular values of $\sqrt{n}(X - E_X)$, where $X$ is a random doubly stochastic matrix. Then the empirical spectral measure $\frac{1}{n} \sum_{i \leq n} \delta_{\sigma_i}$ converges in probability and in weak topology to the quarter-circle measure $\frac{1}{\pi} \sqrt{4 - x^2} 1_{[0,2]} dx$.

The key ingredients in the proof of Theorem 1.6 are a sharp concentration result coupled with two transference principles (Lemmas 2.2 and 2.3 below). These principles help translate results from i.i.d. random matrices of independent random exponential variables to random doubly stochastic matrices.

It has been conjectured in [9] that the empirical spectral distribution of $\sqrt{n}(X - E_X)$ obeys the circular law, which we confirm now. For the rest of this section we sketch the general plan to attack Theorem 1.5.

Since the entries of $X$ are exchangeable, $E_X$ is the matrix $J_n$ of all $1/n$. The matrix $X - E_X$ has a zero eigenvalue, and we want to single this outlier out due to several technical reasons. One way to do this is passing to $\bar{X}$, a matrix of size $(n-1) \times (n-1)$ defined as

$$\bar{X} := \begin{pmatrix} x_{22} - x_{21} & \cdots & x_{2n} - x_{21} \\ x_{32} - x_{31} & \cdots & x_{3n} - x_{31} \\ \vdots & \ddots & \vdots \\ x_{n2} - x_{n1} & \cdots & x_{nn} - x_{n1} \end{pmatrix}.$$

It is not hard to show that the spectra of $\sqrt{n}(X - E_X)$ is the union of zero and the spectra of $\sqrt{n}X$. Indeed, consider the matrix $\lambda I_n - \sqrt{n}(X - E_X)$. By adding all other rows to its first row, and then subtracting the first column from every other column, we arrive at a matrix whose determinant is $\lambda \det(\lambda I_{n-1} - \sqrt{n}X)$, thus confirming our observation. Hence, it is enough to prove the circular law for $\bar{X}$.

Theorem 1.7 (Main theorem). Let $X$ be a matrix chosen uniformly from the set of doubly stochastic matrices. Then the ESD of the matrix $\sqrt{n}\bar{X}$ converges almost surely to $\mu_{\text{cir}}$.

One way to prove our main result above is by showing that the Stieltjes transform of $\mu_{\sqrt{n}X}$ converges to that of the circular measure. However, it is slightly more convenient to work with the logarithmic potential. We will mainly rely on the following machinery from [36], Theorem 2.1.

Lemma 1.8. Suppose that $M = (m_{ij})_{1 \leq i, j \leq n}$ is a random matrix. Assume that:

- $\frac{1}{n} \|M\|_{H_S}^2 = \frac{1}{n} \sum_{i,j} m_{ij}^2$ is bounded almost surely;
for almost all complex numbers $z_0$, the logarithmic potential $\frac{1}{n} \log |\det(M - z_0 I_n)|$ converges almost surely to $f(z_0) = \int_C \log |w - z_0| \, d\mu_{\text{cir}}(w)$.

Then $\mu_M$ converges almost surely to $\mu_{\text{cir}}$.

We will break the main task into two parts, one showing the boundedness and one proving the convergence.

**Theorem 1.9.** Let $X$ be a matrix chosen uniformly from the set of doubly stochastic matrices. Then there exists a constant $C$ such that the following holds:

$$
P \left( \sum_{2 \leq i,j \leq n} (x_{ij} - x_{i1})^2 \geq C \right) = O(\exp(-\Theta(\sqrt{n}))).$$

The proof of Theorem 1.9 will be presented at the end of Section 2. The heart of our paper is to establish the convergence of $\frac{1}{n} \log |\det(\sqrt{n} X - z_0 I_{n-1})|$. 

**Theorem 1.10.** For almost all complex numbers $z_0$, $\frac{1}{n} \log |\det(\sqrt{n} X - z_0 I_{n-1})|$ converges almost surely to $f(z_0)$.

The main difficulty in establishing Theorem 1.10 is that the entries in each row and each column of $X$ are not at all independent. To the best of our knowledge, the convergence for such a model has not been studied before in the literature. We will present its proof in Section 6.

**Notation.** Here and later, asymptotic notation such as $O, \Omega, \Theta$ and so forth, are used under the assumption that $n \to \infty$. A notation such as $O_C(\cdot)$ emphasizes that the hidden constant in $O$ depends on $C$.

For a matrix $M$, we use the notation $r_i(M)$ and $c_j(M)$ to denote its $i$th row and $j$th column, respectively. For an event $A$, we use the subscript $P_x(A)$ to emphasize that the probability under consideration is taking according to the random vector $x$.

For a real or complex vector $v = (v_1, \ldots, v_n)$, we will use the shorthand $\|v\|$ for its $L_2$-norm $(\sum_i |v_i|^2)^{1/2}$.

**2. Some properties of random doubly stochastic matrices.** We will gather here some basic properties of random doubly stochastic matrices. The reader is invited to consult [9] for further insights and applications.

2.1. **Relation to random i.i.d. matrix of exponentials.** Let $\mathcal{M}_n$ be the Birkhoff polytope generated by the permutation matrices. Let $\Phi$ be the projection from $\mathbb{R}^{n^2}$ to $\mathbb{R}^{(n-1)^2}$ by mapping $(x_{ij})_{1 \leq i,j \leq n}$ to $(x_{ij})_{2 \leq i,j \leq n}$. 

Let $\Gamma : \mathbb{R}^{(n-1)^2} \to \mathbb{R}^{n^2}$ denote the following function:

$$
\Gamma(X)_{ij} := \begin{cases} 
  x_{ij}, & 2 \leq i, j \leq n; \\
  1 - \sum_{k=2}^{n} x_{ik}, & 2 \leq i \leq n, j = 1; \\
  1 - \sum_{k=2}^{n} x_{kj}, & 2 \leq j \leq n, i = 1; \\
  1 - \sum_{l=2}^{n} \left(1 - \sum_{k=2}^{n} x_{kl}\right), & i = j = 1.
\end{cases}
$$

Thus $\Gamma$ extends a matrix $X$ of size $(n-1) \times (n-1)$ to a doubly stochastic matrix of size $n \times n$ whose bottom right corner is $X$. With the above notation, the doubly stochastic matrices correspond to $(n-1) \times (n-1)$-matrices of the set

$$
S_n := \{ X = (x_{ij})_{2 \leq i,j \leq n} \in [0,1]^{(n-1)^2} : 0 \leq \Gamma(X)_{ij} \leq 1 \}.
$$

The distribution of $X$ as a random doubly stochastic matrix is then given by the uniform distribution on $S_n$. We next introduce an asymptotic formula by Canfield and Mckay [7] for the volume of $S_n$,

$$
(2.1) \quad \text{Vol}(S_n) = \frac{1}{n^{n-1}} \frac{1}{(2\pi)^{n-1/2} n^{(n-1)/2}} \exp \left( \frac{1}{3} + n^2 + o(1) \right).
$$

This formula plays a crucial role in the transference principles to be introduced next.

Define

$$
D_n := \left\{ Y = (y_{ij})_{1 \leq i,j \leq n} : \Phi \left( \frac{1}{n} Y \right) \in S_n, \min \left\{ \frac{1}{n} y_{ij} - \Gamma \left( \frac{1}{n} Y \right) \right\} \geq 0 \right\},
$$

where $\Phi : \mathbb{R}^{n^2} \to \mathbb{R}^{(n-1)^2}$ is the projection $X = (x_{ij})_{1 \leq i,j \leq n} \mapsto (x_{ij})_{2 \leq i,j \leq n}$. Let $Y = (y_{ij})_{1 \leq i,j \leq n}$ be a random matrix where $y_{ij}$ are i.i.d. copies of a random exponential variable with mean one. As an application of (2.1), it is not hard to deduce the following transference principle between random doubly stochastic matrices $X$ and random i.i.d. matrices $Y$.

**Lemma 2.2** ([9], Lemma 2.1). Conditioning on $Y \in D_n$, we have that $(\frac{1}{n} y_{ij})_{2 \leq i,j \leq n}$ is uniform on $S_n$. Furthermore, for large $n$ we have

$$
P(Y \in D_n) \geq n^{-4n}.
$$

Lemma 2.2 is useful when we want to pass an extremely rare event from the model $\frac{1}{n} Y$ to the model $X$. In applications (in particular when working with concentration results), it is more useful to work with matrices of
bounded entries. With this goal in mind we define

\[ \tilde{S}_n := \left\{ \tilde{X} = (\tilde{x}_{ij})_{2 \leq i, j \leq n} \in [0, 1]^{(n-1)^2} : 0 \leq \Gamma(\tilde{X})_{ij} \leq \frac{10 \log n}{n} \right\} \]

and

\[ \tilde{D}_n := \left\{ \tilde{Y} = (\tilde{y}_{ij})_{1 \leq i, j \leq n} \in [0, 10 \log \frac{n}{n}]^{n^2} : \frac{1}{n} \tilde{Y} \in \tilde{S}_n, \\
0 \leq \frac{1}{n} \tilde{y}_{ij} - \Gamma \left( \Phi \left( \frac{1}{n} \tilde{Y} \right) \right)_{ij} \leq n^{-4} \right\}. \]

Observe that \( \tilde{S}_n \) corresponds to doubly stochastic matrices \( \tilde{X} \) with entries bounded by \( \frac{10 \log n}{n} \).

Let \( \tilde{Y} = (\tilde{y}_{ij})_{1 \leq i, j \leq n} \) where \( \tilde{y}_{ij} \) are i.i.d. copies of a truncated exponential \( \tilde{y} \) with the following density function:

\[ \rho_{\tilde{y}}(x) = \begin{cases} \exp(-x)/(1 - n^{-10}), & \text{if } x \in [0, 10 \log n], \\
0, & \text{otherwise.} \end{cases} \] (2.2)

It is clear that \( \mathbb{E}(\tilde{y}^2) = \Theta(1) \) and \( \mathbb{E}(\tilde{y}^4) = \Theta(1) \). We now introduce another transference principle which is an analogue of Lemma 2.2.

**Lemma 2.3** ([9], Lemma 4.1). Conditioning on \( \tilde{Y} \in \tilde{D}_n \), we have that \( \frac{1}{n} \tilde{y}_{ij} \) is uniform on \( \tilde{S}_n \). Furthermore, for large \( n \) we have

\[ \mathbb{P}(\tilde{Y} \in \tilde{D}_n) \geq n^{-10n}. \]

Notice that in the corresponding definition of \( \tilde{D}_n \) in [9], Section 4, the bound \( 10 \log n \) was replaced by \( 6 \log n \), but one can easily check that this modification does not affect the validity of Lemma 2.3.

2.4. Relation to random stochastic matrices. Let \( \mathcal{R} = \mathcal{R}_{r,n} \) denote the \( r(n-1) \)-dimensional polytope of nonnegative matrices of size \( r \times n \) whose rows sum to 1. Let \( \mu_r \) denote the uniform probability measure on \( \mathcal{R} \), and let \( \nu_r \) denote the measure on \( \mathcal{R} \) induced by the first \( r \) rows of a random doubly stochastic matrix \( \tilde{X} \). As another application of (2.1) (to be more precise, we need a more general form for volume of polytopes generated by rectangular matrices of constant row and column sums), one can show that these two measures are comparable as long as \( r \) is small.

**Lemma 2.5** ([9], Lemma 3.3). For a fixed integer \( r \geq 1 \) and \( n > r \) the Radon–Nikodym derivative of the measures \( \mu_r \) and \( \nu_r \) satisfies

\[ \frac{d\nu_r}{d\mu_r} \leq (1 + o(1)) \exp(r/2) \]

as \( n \to \infty \).
It then follows that, in terms of order, there is not much difference between the models $X$ and $\tilde{X}$.

**Theorem 2.6.** Assume that $B > 4$ is a constant, then

$$P_X(n^{-B} \leq nx_{11} \leq B \log n) \geq 1 - O(n^{-B/2}).$$

In particular, since the entries of $X$ are exchangeable, Theorem 2.6 yields the following.

**Corollary 2.7.** Assume that $X$ is a random doubly stochastic matrix, then

$$P(X \in \tilde{S}_n) = P(|x_{ij}| \leq 10 \log n/n \text{ for all } 1 \leq i, j \leq n) \geq 1 - O(n^{-3}).$$

**Proof of Theorem 2.6.** It follows from Lemma 2.5 (for $r = 1$) that

$$P(n^{-B} \leq nx_{11} \leq B \log n) \leq (1 + o(1)) \exp(1/2)P(n^{-B} \leq nx_1 \leq B \log n),$$

where $x_1$ has distribution $B(1, n - 1)$.

The claim then follows because

$$P(n^{-B} \leq nx_1 \leq B \log n) = (n - 1) \int_{n^{-B}}^{B} (1 - x)^{n-2} dx$$

$$= 1 - (n - 1) \left( \int_0^{n^{-B}} (1 - x)^{n-2} dx + \int_{B \log n}^1 (1 - x)^{n-2} dx \right)$$

$$\geq 1 - O(n^{-B/2}).$$

We end this section by giving a proof for the boundedness of Lemma 1.8.

2.8. A proof for Theorem 1.9. We first focus on the random vector $x = (x_1, \ldots, x_n)$ chosen uniformly from the simplex $S = \{x = (x_1, \ldots, x_n), 0 \leq x_i \leq 1, \sum_i x_i = 1\}$. Because each $x_i$ has distribution $B(1, n - 1)$, we have

$$E_x\|x\|^2 = \frac{2}{n+1}. \quad (2.3)$$

Also, it can be shown that (e.g., from [23], equation (19))

$$E_x x_1 x_2 = \frac{1}{n(n+1)}. \quad (2.4)$$

It thus follows from (2.3) that $\|x\| = O(1/\sqrt{n})$ with high probability. It turns out that this probability is extremely close to one.
Lemma 2.9. Assume that \( x \) is sampled uniformly from \( S \) and assume that \( \varepsilon > 0 \) is a sufficiently small constant. Then there exists a positive constant \( C > 0 \) such that
\[
P(\|x\| \geq C/\sqrt{n}) \leq \exp(-\varepsilon \sqrt{n}).
\]

We assume Lemma 2.9 for the moment.

Proof of Theorem 1.9. First, it follows from Lemma 2.5 (for \( r = 1 \)) that
\[
P(x_{21}^2 + \cdots + x_{n1}^2 \geq C/n) \\
\leq (1 + o(1)) \exp(1/2)P(x_2^2 + \cdots + x_n^2 \geq C/n) \\
= O(1)P(x_2^2 + x_3^2 + \cdots + x_n^2 \geq C/n),
\]
where \( (x_1, x_2, \ldots, x_n) \) are sampled uniformly from the simplex \( S \). But Lemma 2.9 indicates that the RHS is bounded by \( \exp(-\varepsilon \sqrt{n}) \). Thus
\[
P(x_{21}^2 + \cdots + x_{n1}^2 \geq C/n) = O(\exp(-\varepsilon \sqrt{n})).
\]
(2.5)

And so, as \( x_{ij} \) are exchangeable, for any \( j \) we also have
\[
P(x_{2j}^2 + \cdots + x_{nj}^2 \geq C/n) = O(\exp(-\varepsilon \sqrt{n})).
\]
(2.6)

The claim of Theorem 1.9 then follows because \( \sum_{2 \leq i,j \leq n} (x_{ij} - x_{i1})^2 \geq C \) would imply \( \sum_{i=2}^n x_{ij}^2 \geq C/4n \) for some \( j \). \( \square \)

It remains to prove Lemma 2.9. We show that it is a direct consequence of the following geometric result.

Theorem 2.10 ([30], Theorem 1.1). There exists an absolute constant \( c > 0 \) such that if \( K \) is an isotropic convex body in \( \mathbb{R}^n \), then
\[
P(x \in K, \|x\| \geq c\sqrt{n}L_K t) \leq \exp(-\sqrt{nt})
\]
for every \( t \geq 1 \), where \( L_K \) is the isotropic constant of \( K \).

Observe that, by the triangle inequality, for Lemma 2.9 it is enough to give a similar probability bound for the event \( \|x - (1/n, \ldots, 1/n)\| \geq C/\sqrt{n} \).

We first shift \( S \) to the hyperplane \( H := \{x' = (x'_1, \ldots, x'_n), x'_1 + \cdots + x'_n = 0\} \) by the translation \( x = (x_1, \ldots, x_n) \mapsto (x_1 - 1/n, \ldots, x_n - 1/n) \). We then scale the obtained body by a factor \( \alpha = \Theta(n) \) to obtain a regular simplex \( S' \) of volume one. Elementary computations show that this is an isotropic body of bounded isotropic constant. Indeed, if \( x' = (x'_1, \ldots, x'_n) \) is sampled
uniformly from \( S' \) and if \( \Theta = (\theta_1, \ldots, \theta_n) \) is any unit vector in \( H \), then by (2.3) and (2.4),
\[
\mathbb{E}_{x' \in S'} (x', \Theta)^2 = \mathbb{E}_{x' \in S'} \left( \sum_i \theta_i x'_i \right)^2 = \mathbb{E}_{x' \in S'} \sum_i \alpha^2 \left( \sum_i \theta_i \left( x_i - \frac{1}{n} \right) \right)^2
\]
\[
= \alpha^2 \sum_i \theta_i^2 \left( x_i - \frac{1}{n} \right)^2 + 2\alpha^2 \sum_{i \neq j} \theta_i \theta_j \left( x_i - \frac{1}{n} \right) \left( x_j - \frac{1}{n} \right)
\]
\[
= \alpha^2 \left( \frac{2}{n(n+1)} - \frac{1}{n^2} \right) \sum_i \theta_i^2 + 2\alpha^2 \left( \frac{1}{n(n+1)} - \frac{1}{n^2} \right) \theta_i \theta_j
\]
\[
= \alpha^2 \left( \frac{1}{n(n+1)} \right) \sum_i \theta_i^2 + \alpha^2 \left( \frac{1}{n(n+1)} - \frac{1}{n^2} \right) \left( \sum_i \theta_i \right)^2
\]
\[
= \frac{\alpha^2}{n(n+1)}.
\]

Thus the isotropic constant of \( S' \) is of constant order. Theorem 2.10 applied to \( x' \) yields the following for a sufficiently large constant \( C \):
\[
P(x' \in S', \|x'\| \geq C \sqrt{n}) \leq \exp(-\epsilon \sqrt{n}).
\]
Lemma 2.9 then follows because \( \alpha \|x - (1/n, \ldots, 1/n)\| = \|x'\| \).

**Remark 2.11.** The proof above heavily relies on the isotropic property of the simplex \( S \). It is perhaps more natural to relate \( x = (x_1, \ldots, x_n) \) to \((y_1/(y_1 + \cdots + y_n), \ldots, y_n/(y_1 + \cdots + y_n))\), where \( y_i \) are i.i.d. copies of a random exponential random variable of mean one.\(^2\) The probability \( P(\|x\| \geq C/\sqrt{n}) \) is then bounded by the sum \( P(y_1 + \cdots + y_n \leq n/\sqrt{C}) + P(y_1^2 + \cdots + y_n^2 \geq Cn) \). As now we only need to work with sum of i.i.d. random variables, by choosing \( C \) sufficiently large, it is not hard to show that both \( P(y_1 + \cdots + y_n \leq n/\sqrt{C}) \) and \( P(y_1^2 + \cdots + y_n^2 \geq Cn) \) are bounded from above by \( \exp(-\Theta(\sqrt{n})) \).

3. The singularity of \( X \). In order to justify Theorem 1.10, one of the key steps is to bound the singularity probability of the matrix \( \sqrt{n}X - z_0 I_{n-1} \). This problem is of interest on its own.

We will show the following general result regarding the least singular value \( \sigma_{n-1} \).

**Theorem 3.1.** Let \( F = (f_{ij})_{2 \leq i,j \leq n} \) be a deterministic matrix where \( |f_{ij}| \leq n^\gamma \) with some positive constant \( \gamma \). Let \( X \) be an \( n \times n \) matrix chosen

\(^2\)The author is grateful to the anonymous referee for this suggestion.
uniformly from the set of doubly stochastic matrices. Then for any positive constant $B$ there exists a positive constant $A$ such that

$$
P(\sigma_{n-1}(\bar{X} + F) \leq n^{-A}) \leq n^{-B}.
$$

Combine with Theorem 2.7 we obtain the following important corollary which we reserve for later applications.

**Corollary 3.2.** Let $F = (f_{ij})_{2 \leq i,j \leq n}$ be a deterministic matrix where $|f_{ij}| \leq n^\gamma$ with some positive constant $\gamma$. Let $\bar{X} = (x_{ij})$ be a random doubly stochastic matrix where $x_{ij} \leq 10 \log n/n$ for all $1 \leq i,j \leq n$. Then there exists a positive constant $A$ such that

$$
P(\sigma_{n-1}(\bar{\tilde{X}} + F) \leq n^{-A}) = O(n^{-3}).
$$

Here $\bar{\tilde{X}}$ is obtained from $\tilde{X}$ in the same way that $\bar{X}$ was defined from $X$.

We remark that a similar version of Theorem 3.1 has appeared in [36] to deal with random matrices of i.i.d. entries; see also [6, 28] and the references therein. However, our task here looks much harder as the entries in each row and each column are not independent. We will now sketch the proof of Theorem 3.1; more details will be presented in Section 4.

Assume that $\sigma_{n-1}(\bar{X} + F) \leq n^{-A}$. Then, by letting $C = (c_{ij})_{2 \leq i,j \leq n}$ be the cofactor matrix of $\bar{X} + F$, there exist vectors $x$ and $y$ such that $\|x\| = 1$ and $\|y\| \leq n^{-A}$ and

$$
C y = \det(\bar{X} + F)x.
$$

So

$$
\|Cy\| = |\det(\bar{X} + F)|.
$$

Thus by the Cauchy–Schwarz inequality, with a loss of a factor of $n$ in probability and without loss of generality, we can assume that

$$
\sum_{j=2}^{n} |c_{2j}|^2 \geq n^{2A-1}|\det(\bar{X} + F)|^2. \tag{3.1}
$$

In what follows we fix the matrix $X_{(n-2)\times (n-1)}$ generated by the last $(n-2)$ rows and the last $(n-1)$ columns of $X$ [equivalently, we fix the last $(n-2)$ rows of $\bar{X}$].

Let $s_2, \ldots, s_n$ be the column sums of $X_{(n-2)\times (n-1)}$. By Theorem 2.6, the probability that all $x_{11}, \ldots, x_{1n}, x_{21}, \ldots, x_{2n}$ are greater than $n^{-2B-2}$ is bounded from below by $1 - O(n^{-B})$, in which case we have

$$
s_i \leq 1 - n^{-2B-2} \quad \text{for all } i \geq 2 \quad \text{and} \quad
$$

$$
0 \leq s_1 := (n-2) - (s_2 + \cdots + s_n) \leq 1 - n^{-2B-2}. \tag{3.2}
$$
Thus it is enough to justify Theorem 3.1 conditioning on this event.

Next, given a sequence $s_2, \ldots, s_n$ satisfying (3.2), we will choose $x_2 := x_{22}, \ldots, x_n := x_{2n}$ uniformly and, respectively, from the interval $[0,1-s_2], \ldots, [0,1-s_n]$ such that

$$s_1 \leq x_2 + \cdots + x_n \leq 1. \quad (3.3)$$

The upper bound guarantees that $x_1 := x_{21} = 1 - (x_2 + \cdots + x_n) \geq 0$, while the lower bound ensures that $x_{11} = 1 - s_1 - x_{21} = x_2 + \cdots + x_n - s_1 \geq 0$.

We now express $\det(\bar{X} + F)$ as a linear form of its first row $(x_2 - x_1 + f_{22}, \ldots, x_n - x_1 + f_{2n}),$

$$\det(\bar{X} + F) = \sum_{2 \leq j \leq n} c_{2j}(\bar{X} + F)(x_j - x_1 + f_{2j}).$$

By using the fact that $x_1 = 1 - \sum_{2 \leq j \leq n} x_j$ we can rewrite the above as

$$\det(\bar{X} + F) = \sum_{2 \leq j \leq n} \left( c_{2j} + \sum_{2 \leq i \leq n} c_{2i} \right) x_j + c, \quad (3.4)$$

where $c$ is a constant depending on the $c_{2j}$’s and $f_{2j}$’s.

Observe that

$$\sum_{2 \leq j \leq n} \left| c_{2j} + \sum_{2 \leq i \leq n} c_{2i} \right|^2 \geq \sum_{2 \leq j \leq n} |c_{2j}|^2.$$

Thus, by increasing $A$ if needed, we obtain from (3.1) and (3.4) the following:

$$\left| \sum_{2 \leq j \leq n} x_j a_j + c \right| \leq n^{-A},$$

where

$$a_j := \frac{c_{2j} + \sum_{2 \leq i \leq n} c_{2i}}{(\sum_{2 \leq j \leq n} |c_{2j} + \sum_{2 \leq i \leq n} c_{2i}|^2)^{1/2}}. \quad (3.5)$$

Roughly speaking, our approach to prove Theorem 3.1 consists of two main steps:

- **Inverse step.** Given the matrix $X_{(n-2)\times (n-1)}$ for which all the column sums $s_i$ satisfy (3.2), assume that

  $$\mathbb{P}_{x_2, \ldots, x_n} \left( \left| \sum_{2 \leq j \leq n} a_j x_j + c \right| \leq n^{-A} \right) \geq n^{-B},$$

  where the probability is taken over all $x_i, 2 \leq i$ which satisfy (3.3). Then there is a strong structure among the cofactors $c_{2j}$ of $X_{(n-2)\times (n-1)}$. 
• Counting step. With respect to $X_{(n-2)\times(n-1)}$, the probability that there is a strong structure among the cofactors $c_{2j}$ is negligible.

We pause to discuss the structure mentioned in the inverse step. A set $Q \subset \mathbb{C}$ is a GAP of rank $r$ if it can be expressed as in the form

$$Q = \{g_0 + k_1 g_1 + \cdots + k_r g_r | k_i \in \mathbb{Z}, K_i \leq k_i \leq K'_i \text{ for all } 1 \leq i \leq r\}$$

for some $(g_0, \ldots, g_r) \in \mathbb{C}^{r+1}$ and $(K_1, \ldots, K_r), (K'_1, \ldots, K'_r) \in \mathbb{Z}^r$.

It is convenient to think of $Q$ as the image of an integer box $B := \{(k_1, \ldots, k_r) \in \mathbb{Z}^r | K_i \leq k_i \leq K'_i\}$ under the linear map $\Phi : (k_1, \ldots, k_r) \mapsto g_0 + k_1 g_1 + \cdots + k_r g_r$.

The numbers $g_i$ are the generators of $Q$, the numbers $K'_i$ and $K_i$ are the dimensions of $Q$, and $\text{Vol}(Q) := |B|$ is the size of $B$. We say that $Q$ is proper if this map is one to one, or equivalently if $|Q| = \text{Vol}(Q)$. For nonproper GAPs, we of course have $|Q| < \text{Vol}(Q)$. If $-K_i = K'_i$ for all $i \geq 1$ and $g_0 = 0$, we say that $Q$ is symmetric.

We are now ready to state both of our steps in details.

**Theorem 3.3** (Inverse step). Let $0 < \varepsilon < 1$ and $B > 0$ be given constants. Assume that

$$\mathbb{P}_{x_2, \ldots, x_n} \left( \left| \sum_{2 \leq j \leq n} a_j x_j + c \right| \leq n^{-A} \right) \geq n^{-B}$$

for some sufficiently large integer $A$, where $a_j$ are defined in (3.5), and $x_j$ are chosen uniformly from the intervals $[0, 1-s_i]$ such that the constraint (3.3) holds. Then there exists a vector $u = (u_2, \ldots, u_n) \in \mathbb{C}^{n-1}$ which satisfies the following properties:

• $1/2 \leq ||u|| \leq 2$ and $|\langle u, r_1(\bar{X} + F) \rangle| \leq n^{-|A|+\gamma+2}$ for all but the first row $r_1(\bar{X} + F)$ of $\bar{X} + F$.

• All but $n'$ components $u_i$ belong to a GAP $Q$ (not necessarily symmetric) of rank $r = O_{B, \varepsilon}(1)$, and of cardinality $|Q| = n^{O_{B, \varepsilon}(1)}$.

• All the real and imaginary parts of $u_i$ and of the generators of $Q$ are rational numbers of the form $p/q$, where $|p|, |q| \leq n^{2A+3/2}$.

In the second step of the approach we show that the probability for $X_{(n-2)\times(n-1)}$ having the above properties is negligible.

**Theorem 3.4** (Counting step). With respect to $X_{(n-2)\times(n-1)}$, or equivalently, with respect to the last $(n-2)$ rows of $\bar{X}$, the probability that there exists a vector $u$ as in Theorem 3.3 is $\exp(-\Theta(n))$. 
Proof. First, we show that the number of structural vectors \( \mathbf{u} \) described in Theorem 3.3 is bounded by \( n^{O_{A,B,\varepsilon}(n) + O_A(n^\varepsilon)} \). Indeed, because each GAP is determined by its generators and its dimensions, and because all the real and complex parts of the generators are of the form \( p/q \) where \( |p|, |q| \leq n^{2A+3/2} \), there are \( n^{O_{A,B,\varepsilon}(1)} \) GAPs which have rank \( O_{B,\varepsilon}(1) \) and size \( n^{O_{B,\varepsilon}(1)} \). Next, for each determined GAP \( Q \) of size \( n^{O_{B,\varepsilon}(1)} \), there are \( |Q|^n = n^{O_{B,\varepsilon}(n)} \) ways to choose the \( u_i \) as its elements. For the remaining \( O(n^\varepsilon) \) exceptional \( u_i \) that may not belong to \( Q \), there are \( n^{O_A(n^\varepsilon)} \) ways to choose them as numbers of the form \( p/q \) where \( |p|, |q| \leq n^{2A+3/2} \). Putting these together we obtain the bound as claimed.

Second, as for each fixed structural vector \( \mathbf{u} \) from Theorem 3.3 we have

\[

|\langle \mathbf{u}, r_i(X + F) \rangle| = O(n^{-A+\gamma+2}) \quad \text{for all} \ 2 \leq i \leq n - 1.

\]

(3.6)

Thus there exist \( j_0 \) such that

\[

\sum_{2 \leq j \leq k} \left| u_j + \sum_{2 \leq k} u_k \right|^2 \geq \sum_{2 \leq k \leq n} u_k^2 \geq 1/4.

\]

(3.7)

Observe that

\[

\left| u_{j_0} + \sum_{2 \leq k \leq n} u_k \right| \geq 1/2\sqrt{n}.

\]

It then follows that for each \( i \), with room to spare,

\[

P\left( \sum_{2 \leq j} \frac{1}{n} y_{ij} \left( u_j + \sum_{2 \leq k} u_k \right) - \sum_{2 \leq j} u_j + \sum_{2 \leq j} u_j f_{ij} \right) = O(n^{-A+\gamma+2})

\]

(3.7)

is bounded by \( n^{O_{A,B,\varepsilon}(n) + O_A(n^\varepsilon)} \). Indeed, because each GAP is determined by its generators and its dimensions, and because all the real and complex parts of the generators are of the form \( p/q \) where \( |p|, |q| \leq n^{2A+3/2} \), there are \( n^{O_{A,B,\varepsilon}(1)} \) GAPs which have rank \( O_{B,\varepsilon}(1) \) and size \( n^{O_{B,\varepsilon}(1)} \). Next, for each determined GAP \( Q \) of size \( n^{O_{B,\varepsilon}(1)} \), there are \( |Q|^n = n^{O_{B,\varepsilon}(n)} \) ways to choose the \( u_i \) as its elements. For the remaining \( O(n^\varepsilon) \) exceptional \( u_i \) that may not belong to \( Q \), there are \( n^{O_A(n^\varepsilon)} \) ways to choose them as numbers of the form \( p/q \) where \( |p|, |q| \leq n^{2A+3/2} \). Putting these together we obtain the bound as claimed.

Second, as for each fixed structural vector \( \mathbf{u} \) from Theorem 3.3 we have

\[

|\langle \mathbf{u}, r_i(X + F) \rangle| = O(n^{-A+\gamma+2}) \quad \text{for all} \ 2 \leq i \leq n - 1.

\]

(3.6)

Thus there exist \( j_0 \) such that

\[

\left| u_{j_0} + \sum_{2 \leq k \leq n} u_k \right| \geq 1/2\sqrt{n}.

\]

It then follows that for each \( i \), with room to spare,
\[= O(n^{-A+\gamma+2}) | y_{ij, j \neq j_0} \]
\[= O(n^{-A+\gamma+10}), \]

where in the last conditional probability estimate we used the fact that \( y_{ij} \) are i.i.d. exponentials of mean one.

Hence, for each fixed structural vector \( u \), the probability \( P_u \) that (3.7) holds for all rows \( r_i(\bar{Y} + F), 2 \leq i \leq n - 1 \), is bounded by

\[P_u \leq n^{(-A+\gamma+10)(n-2)}.
\]

Summing over structural vectors \( u \), we thus obtain the following upper bound for the probability that there exists a structural vector \( u \) for which (3.7) holds for all rows \( r_i(\bar{Y} + F), 2 \leq i \leq n - 1 \)

\[\sum_u P_u \leq n^{O_B, \varepsilon(n) + O_A(n^\varepsilon) n^{(-A+\gamma+10)(n-2)} = O(n^{-An/2}),}

provided that \( A \) is large enough.

To conclude the proof of Theorem 3.4, we use Lemma 2.2 to pass from \( Y \) and \( \bar{Y} \) back to \( X \) and \( \bar{X} \). The probability that there exists a structural vector \( u \) for which (3.6) holds for all rows \( r_i(\bar{X} + F), 2 \leq i \leq n - 1 \), is then bounded by \( O(n^{-An/2+4n}) = O(\exp(-\Theta(n))) \), provided that \( A \) is sufficiently large. \( \square \)

4. Proof of Theorem 3.3. We recall from the assumptions of Theorem 3.3 that

\[P_{x_2, \ldots, x_n} \left( \left| \sum_{j \geq 2} a_j x_j + c \right| \leq n^{-A} \right) \geq n^{-B}, \tag{4.1}\]

where \( x_2, \ldots, x_n \) are uniformly sampled from the interval \([0, 1 - s_2], \ldots, [0, 1 - s_n]\), respectively, so that (3.3) holds.

This is a large concentration inequality for linear forms of mildly dependent random variables. Our first goal is to relax these dependencies.

4.1. A simple reduction step. Let \( E_n \) be the set of all \( (x_2, \ldots, x_n) \) uniformly sampled from \([0, 1 - s_2] \times \cdots \times [0, 1 - s_n]\) so that (3.3) holds. We recall from (3.2) that \( s_1 \leq 1 - n^{-2B^2-2} \).

Consider the event \( s_1 \leq x'_2 + \cdots + x'_n \leq 1 \), where \( x'_i \) are independently and uniformly sampled from the interval \([0, 1 - s_i]\), respectively.

Note that \( E(x'_2 + \cdots + x'_n) = \sum_{2 \leq i \leq n} (1 - s_i)/2 = (1 - s_1)/2 \). Since the random variables \( x'_i - (1 - s_i)/2 \) are symmetric and uniform, the density
function $f(x)$ of $x_1' + \cdots + x_n'$ is maximized at $(1 - s_1)/2$ and decreases as $\lvert x - (1 - s_1)/2\rvert$ increases. Thus we have

\[
P((x_1', \ldots, x_n') \in E_n) = P(s_1 \leq x_1' + \cdots + x_n' \leq 1)
= \int_{s_1}^{1} f(x) \, dx = \frac{\int_{s_1}^{1} f(x) \, dx}{\int_{0}^{(1 - s_2) + \cdots + (1 - s_n)} f(x) \, dx}
\geq \frac{1 - s_1}{(1 - s_2) + \cdots + (1 - s_n)} = \frac{1 - s_1}{1 + s_1}
= \Omega(n^{-2B - 2}),
\]

where we noted from (3.2) that $s_1 \leq 1 - n^{-2B - 2}$.

Observe that if we condition on $s_n \leq x_1' + \cdots + x_n' \leq 1$, then the distribution of $(x_1', \ldots, x_n')$ is uniform over the set $E_n$. It thus follows from (4.1) that

\[
P_{x_2', \ldots, x_n'}\left(\sum_{j \geq 2} a_j x_j' + c \leq n^{-A}\right) \geq n^{-3B - 2}.
\]

In the next step of the reduction, we divide the intervals $[0, 1 - s_i]$ into disjoint intervals $I_{i_1}, \ldots, I_{ik_i}$ of length $n^{-3B - 2}$, where $k_i = (1 - s_i)/n^{-3B - 2}$ (without loss of generality, we assume that $k_i$ are integers). Next, to sample $x_i'$ uniformly from the interval $[0, 1 - s_i]$ we first choose at random an interval from $\{I_{i_1}, \ldots, I_{ik_i}\}$ and then sample $x_i'$ from it. In this way, (4.2) implies that there exist intervals $I_{ij}, 2 \leq i \leq n$, such that if $x_i'$ are chosen uniformly from $I_{ij}$ then

\[
P_{x_2', \ldots, x_n'}\left(\sum_{j \geq 2} a_j x_j' + c \leq n^{-A}\right) \geq n^{-3B - 2}.
\]

Observe furthermore that, by shifting $c$ if needed, we can assume that $I_{ij} = [0, n^{-3B - 2}]$ for all $i$. Finally, by passing to $x_i'' := n^{3B + 2} x_i'$ and by decreasing $A$ to $A - (3B + 2)$, we can assume that all $x_i'$ are uniformly sampled from the interval $[0, 1]$.

### 4.2. High concentration of linear form.

A classical result of Erdős [12] and Littlewood–Offord [22] asserts that if $b_i$ are real numbers of magnitude $\lvert b_i \rvert \geq 1$, then the probability that the random sum $\sum_{i=1}^{n} b_i x_i$ concentrates on an interval of length one is of order $O(n^{-1/2})$, where $x_i$ are i.i.d. copies of a Bernoulli random variable. This remarkable inequality has generated an impressive amount of research, particularly from the early 1960s to the late 1980s. We refer the reader to [19, 21] and the references therein for these developments.
Motivated by inverse theorems from additive combinatorics, Tao and Vu studied the underlying reason as to why the concentration probability of \( \sum_{i=1}^{n} b_i x_i \) on a short interval is large. A closer look at the definition of GAPs defined in the previous section reveals that if \( b_i \) are very close to the elements of a GAP of rank \( O(1) \) and size \( n^{O(1)} \), then the concentration probability of \( \sum_{i=1}^{n} b_i x_i \) on a short interval is of order \( n^{-O(1)} \), where \( x_i \) are i.i.d. copies of a Bernoulli random variable.

It has been shown by Tao and Vu \([35–37]\) in an implicit way, and by the current author and Vu \([27]\) in a more explicit way that these are essentially the only examples that have high concentration probability.

We say that a complex number \( a \) is \( \delta \)-close to a set \( Q \subset \mathbb{C} \) if there exists \( q \in Q \) such that \( |a - q| \leq \delta \).

**Theorem 4.3** (Inverse Littlewood–Offord theorem for linear forms \([27]\), Corollary 2.10). Let \( 0 < \varepsilon < 1 \) and \( C > 0 \). Let \( \beta > 0 \) be an arbitrary real number that may depend on \( n \). Suppose that \( b_i = (b_{i1}, b_{i2}) \) are complex numbers such that \( \sum_{i=1}^{n} \| b_i \|^2 = 1 \), and

\[
\sup_{a} \mathbb{P}_{\mathbf{x}} \left( \left| \sum_{i=1}^{n} b_i x_i - a \right| \leq \beta \right) = \rho \geq n^{-C},
\]

where \( \mathbf{x} = (x_1, \ldots, x_n) \), and \( x_i \) are i.i.d. copies of random variable \( \xi \) satisfying \( \mathbb{P}(c_1 \leq \xi - \xi' \leq c_2) \geq c_3 \) for some positive constants \( c_1, c_2 \) and \( c_3 \). Then, for any number \( n' \) between \( n^\varepsilon \) and \( n \), there exists a proper symmetric GAP \( Q = \{ \sum_{i=1}^{r} k_i g_i : k_i \in \mathbb{Z}, |k_i| \leq L_i \} \) such that:

- at least \( n - n' \) numbers \( b_i \) are \( \beta \)-close to \( Q \);
- \( Q \) has small rank, \( r = O_{C,\varepsilon}(1) \), and small cardinality

\[
|Q| \leq \max \left( O_{C,\varepsilon} \left( \frac{\rho^{-1}}{\sqrt{n'}} \right), 1 \right);
\]

- there exists a nonzero integer \( p = O_{C,\varepsilon}(\sqrt{n'}) \) such that all generators \( g_i = (g_{i1}, g_{i2}) \) of \( Q \) have the form \( g_{ij} = \beta p_{ij} \), with \( p_{ij} \in \mathbb{Z} \) and \( |p_{ij}| = O_{C,\varepsilon}(\beta^{-1} \sqrt{n'}) \).

Theorem 4.3 was proved in \([27]\) with \( c_1 = 1, c_2 = 2 \) and \( c_3 = 1/2 \), but the proof there automatically extends to any constants \( 0 < c_1 < c_2 \) and \( 0 < c_3 \).

The interested reader is invited to also read \([26, 31, 40]\) for other variants and further developments of such inverse results.

We now prove Theorem 3.3. Theorem 4.3 applied to \((4.3)\), with \( n' = n^\varepsilon, C = 3B + 2 \) and \( x_i \) being independently and uniformly distributed over the interval \([0, 1]\), implies that there exists a vector \( \mathbf{v} = (v_2, \ldots, v_n) \) such that:

- \( |a_i - v_i| \leq n^{-A} \) for all indices \( i \) from \( \{2, \ldots, n\} \);
all but \( n' \) numbers \( v_i \) belong to a GAP \( Q \) of small rank, \( r = O_{B,\varepsilon}(1) \), and of small cardinality \( |Q| = O(n^{O_{B,\varepsilon}(1)}) \);

- all the real and imaginary parts of \( v_i \) and of the generators of \( Q \) are rational numbers of the form \( p/q \), with \( p, q \in \mathbb{Z} \) and \( |p|, |q| = O_{B,\varepsilon}(n^{A+1/2}) \).

Recall that
\[
a_j = \frac{c_{2j} + \sum_{2 \leq i \leq n} c_{2i}}{(\sum_{2 \leq j \leq n} |c_{2j} + \sum_{2 \leq i \leq n} c_{2i}|^2)^{1/2}}.
\]

We will translate the above useful information on the \( a_j \)'s to the \( c_j \)'s. To do so first find a number of the form \( p/n \), with \( p \in \mathbb{Z} \) and \(-n^A \leq p \leq n^A\) such that
\[
| p - \sum_{2 \leq j \leq n} c_{2j} | (\sum_{j} |c_{2j} + \sum_{2 \leq i \leq n} c_{2i}|^2)^{1/2} \leq \frac{1}{n^A}.
\]

Thus, by shifting the GAP \( Q \) by \( p/n^A \), we obtain \(|a'_j - v'_j| \leq 2n^{-A}\), and so
\[
\|a' - v'\| = O(n^{-A+1/2}),
\]
where \( a' = (a'_2, \ldots, a'_n), v' = (v'_2, \ldots, v'_n) \) and
\[
a'_j = \frac{c_{2j}}{(\sum_{j} |c_{2j} + \sum_{2 \leq i \leq n} c_{2i}|^2)^{1/2}} \quad \text{as well as} \quad v'_j = v_j - \frac{p}{n^A}.
\]

By definition, \( 1/2n^2 \leq \sum |a'_j|^2 \leq 1 \), so by the triangle inequality
\[
\|v'\| \geq \|a'\| - O(n^{-A+1/2}) \geq 1/\sqrt{2}n - O(n^{-A+1/2})
\]
and
\[
\|v'\| \leq \|a'\| + O(n^{-A+1/2}) \leq 1 + O(n^{-A+1/2}).
\]

More importantly, as \( a' \) is proportional to \( (c_{22}, \ldots, c_{2n}) \) (which are the cofactors of \( \bar{X} + F \)), \( a' \) is orthogonal to all but the first row of \( \bar{X} + F \). In other words, \(|\langle a', r_i(\bar{X} + F) \rangle| = 0 \) for all \( i \geq 2 \). It is thus implied that
\[
|\langle v', r_i(\bar{X} + F) \rangle| \leq n^{-A+\gamma+1}.
\]

In the last step of the proof, we find nonzero numbers \( p', q' \in \mathbb{Z}, |p'|, |q'| = O(n) \) so that \|v'\|/2 \leq p'/q' \leq 2\|v'\|.

Set
\[
u := \frac{q'}{p'}v',
\]
and we then have:

- \( 1/2 \leq \|u\| \leq 2 \) and \( \langle u, r_i(\bar{X} + F) \rangle \leq n^{-A+\gamma+2} \) for all but the first rows of \( \bar{X} + F \).
all but $n'$ components $u_i$ belong to a GAP $Q'$ (not necessarily symmetric) of small rank, $r = O_{B, \varepsilon}(1)$, and of small cardinality $|Q'| = O(n^{O_{B, \varepsilon}(1)})$;

- all the real and imaginary parts of $u_i$ and of the generators of $Q'$ are rational numbers of the form $p/q$, with $p, q \in \mathbb{Z}$ and $|p|, |q| = O_{B, \varepsilon}(n^{2A+3/2})$.

5. Spectral concentration of i.i.d. random covariance matrices. From now on we will mainly focus on the bounded model $\tilde{X}$ rather than on $X$. This is the model where we can relate to $\hat{Y}$, a matrix of bounded i.i.d. entries (defined in Section 2) for which concentration results may easily apply. Furthermore, by Corollary 2.7, there is not much difference between the two models $X$ and $\tilde{X}$.

Having learned from Corollary 3.2 that $|\det(\sqrt{n}X - z_0I_{n-1})|$ is bounded away from zero, we will show that $\frac{1}{n} \log |\det(\sqrt{n}X - z_0I_{n-1})|$ is well concentrated around its mean. This result will then immediately imply Theorem 1.10.

In order to study the concentration of $\det(\sqrt{n}X - z_0I_{n-1})$, we might first relate it to the counterpart $\tilde{Y}$. However, the entries of the later model are not independent, and so certain well-known concentration results for i.i.d. matrices are not applicable. To avoid this technical issue, we will modify $\sqrt{n}X$ as follows. Observe that

$$\det(\sqrt{n}X - z_0I_{n-1}) = \frac{1}{\sqrt{n}} \det(\sqrt{n}X_{(n-1)\times n} - F_{20}),$$

where $F_{20}$ is the deterministic matrix obtained from $z_0I_{n-1}$ by attaching $(-\sqrt{n}, \ldots, -\sqrt{n})$ and $(-\sqrt{n}, 0, \ldots, 0)^T$ as its first row and first column, respectively, and $X_{(n-1)\times n}$ is the matrix obtained from $X$ by replacing its first row by a zero vector,

$$\sqrt{n}X_{(n-1)\times n} - F_{20} := \begin{pmatrix} \sqrt{n} & \sqrt{n} & \cdots & \sqrt{n} \\ \sqrt{n}x_{11} & \sqrt{n}x_{22} - z_0 & \cdots & \sqrt{n}x_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \sqrt{n}x_{n1} & \sqrt{n}x_{n2} & \cdots & \sqrt{n}x_{nn} - z_0 \end{pmatrix}.$$

As it turns out, it is more pleasant to work with $X_{(n-1)\times n}$ because the entries of its counterpart $\tilde{Y}_{(n-1)\times n}$ are now independent. To relate the singularity of $\sqrt{n}X - z_0I_{n-1}$ to that of $\sqrt{n}X_{(n-1)\times n} - F_{20}$, we have a crucial observation below.

Claim 5.1. Suppose that $A$ is a sufficiently large constant. We have

$$\sigma_n(\sqrt{n}X_{(n-1)\times n} - F_{20}) \geq \frac{1}{n} \min \left( \frac{1}{\sqrt{2n}} \sigma_{n-1}(\sqrt{n}X - z_0I_{n-1}) - O(n^{-A}), n^{-A} \right).$$
To prove this claim, let $c_1, \ldots, c_n$ be the columns of $\sqrt{n}X_{(n-1)\times n} - F_{z_0}$.
Let $v = (v_1, \ldots, v_n)$ be any unit vector. If $|v_1 + \cdots + v_n| \geq n^{-A - 1/2}$, then it is clear that $\|(\sqrt{n}X_{(n-1)\times n} - F_{z_0})v\| \geq |\sqrt{n}(v_1 + \cdots + v_n)| \geq n^{-A}$.
Otherwise, as $|v_1^2 + \cdots + |v_n|^2 = 1$, we can easily deduce that $|v_1|^2 + \cdots + |v_n|^2 \geq 1/2n$.
Next, by the triangle inequality,
\[
\|(\sqrt{n}X_{(n-1)\times n} - F_{z_0})v\| = \left\| \sum_{2 \leq i \leq n} v_i c_i \right\| = \left\| \sum_{2 \leq i \leq n} v_i (c_i - c_1) + (v_1 + \cdots + v_n)c_1 \right\|
\geq \left\| \sum_{2 \leq i \leq n} v_i c_i \right\| - n^{-A - 1/2}\|c_1\|
\geq (|v_2|^2 + \cdots + |v_n|^2)^{1/2} \sigma_{n-1}(\sqrt{n}X - z_0I_{n-1}) - \sqrt{2}n^{-A}
\geq \frac{1}{\sqrt{2n}} \sigma_{n-1}(\sqrt{n}X - z_0I_{n-1}) - O(n^{-A}).
\]

Claim 5.1 guarantees that the polynomial probability bound for $\sigma_{n-1}(\sqrt{n}X - z_0I_{n-1})$ from Corollary 3.2 continues to hold for $\sigma_n(\sqrt{n}X_{(n-1)\times n} - F_{z_0})$ (with probably a worse value of $A$).

\textbf{THEOREM 5.2.} \textit{There exists a positive constant $A$ such that}
\[
P(\sigma_n(\sqrt{n}X_{(n-1)\times n} - F_{z_0}) \leq n^{-A}) = O(n^{-3}).
\]

Our goal is then to establish a large concentration of $\frac{1}{n} \log |\det(\sqrt{n}X_{(n-1)\times n} - F_{z_0})|$ around its mean. We now consider $\hat{Y}$.

5.3. \textit{Large concentration for $\hat{Y}$}. Consider the i.i.d. matrices $\hat{Y}$ defined from Section 2, and let $\hat{Y}_{(n-1)\times n}$ be the matrix obtained from $\hat{Y}$ by replacing its first row by the zero vector.

We first observe from Claim 5.1 that
\[
\sigma_n\left(\frac{1}{\sqrt{n}} \hat{Y}_{(n-1)\times n} - F_{z_0}\right)
\geq \frac{1}{n} \min\left(\frac{1}{\sqrt{2n}} \sigma_{n-1}\left(\frac{1}{\sqrt{n}} \hat{Y} - z_0I_{n-1}\right) - O(n^{-A}), n^{-A}\right),
\]
where
\[
\frac{1}{\sqrt{n}} \hat{Y}_{(n-1)\times n} - F_{z_0} = \begin{pmatrix}
\frac{1}{\sqrt{n}} \hat{y}_{21} & \frac{1}{\sqrt{n}} \hat{y}_{22} - z_0 & \cdots & \frac{1}{\sqrt{n}} \hat{y}_{2n} \\
\frac{1}{\sqrt{n}} \hat{y}_{n1} & \frac{1}{\sqrt{n}} \hat{y}_{n2} & \cdots & \frac{1}{\sqrt{n}} \hat{y}_{nn} - z_0 \\
\vdots & \vdots & \ddots & \vdots \\
\frac{1}{\sqrt{n}} \hat{y}_{n1} & \frac{1}{\sqrt{n}} \hat{y}_{n2} & \cdots & \frac{1}{\sqrt{n}} \hat{y}_{nn} - z_0
\end{pmatrix}.
\]
On the other hand, conditioning on $\tilde{y}_{21}, \ldots, \tilde{y}_{n1}$, the entries $\tilde{y}_{ij} - \bar{y}_{i1}$ of the matrix $\tilde{Y}$ are independent, and so we can apply known singularity bounds, for instance [34], Theorem 2.1, for i.i.d. matrices to conclude that for any positive constant $B$, there exists a positive constant $A$ such that $\mathbf{P}(\sigma_{n-1}(\frac{1}{\sqrt{n}}\tilde{Y} - z_0 I_{n-1}) \leq n^{-A}) = O(n^{-B})$. Returning to $\tilde{Y}_{(n-1)\times n}$, we hence obtain the following.

**Theorem 5.4.** For any positive constant $B$, there exists a positive constant $A$ such that

$$\mathbf{P}\left(\sigma_n\left(\frac{1}{\sqrt{n}}\tilde{Y}_{(n-1)\times n} - F_{z_0}\right) \leq n^{-A}\right) = O(n^{-B}).$$

This bound will be exploited later on.

Next, let $H$ denote the following Hermitian matrix:

$$H := \left(\frac{1}{\sqrt{n}}\tilde{Y}_{(n-1)\times n} - F_{z_0}\right)^* \left(\frac{1}{\sqrt{n}}\tilde{Y}_{(n-1)\times n} - F_{z_0}\right).$$

It is clear that the eigenvalues $\lambda_1(H), \ldots, \lambda_n(H)$ of $H$ can be written as

$$\lambda_1(H) = \sigma_1^2\left(\frac{1}{\sqrt{n}}\tilde{Y}_{(n-1)\times n} - F_{z_0}\right), \ldots, \lambda_n(H) = \sigma_n^2\left(\frac{1}{\sqrt{n}}\tilde{Y}_{(n-1)\times n} - F_{z_0}\right),$$

where $\sigma_i\left(\frac{1}{\sqrt{n}}\tilde{Y}_{(n-1)\times n} - F_{z_0}\right)$ are the singular values of $\frac{1}{\sqrt{n}}\tilde{Y}_{(n-1)\times n} - F_{z_0}$.

The following concentration result will serve as our main lemma.

**Lemma 5.5.** Assume that $f$ is a function so that $g(x) := f(x^2)$ is convex and has finite Lipschitz norm $\|g\|_L$. Then for any $\delta \geq CK\|g\|_L/\sqrt{n}$, where $K = 10\log n$ is the upper bound for the entries of $\tilde{Y}_{(n-1)\times n}$ and $C$ is a sufficiently large absolute constant, we have

$$\mathbf{P}\left(\left|\sum_{i=1}^{n} f(\lambda_i(H)) - \mathbf{E}\left(\sum_{i=1}^{n} f(\lambda_i(H))\right)\right| \geq \delta n\right) = O\left(\exp\left(-C'\frac{n^2\delta^2}{K^2\|g\|_L^2}\right)\right);$$

here $C'$ and the implied constant depend on $C$.

We remark that when $F_{z_0}$ vanishes, Lemma 5.5 is essentially [18], Corollary 1.8, of Guionnet and Zeitouni. We will show that the method there can be easily extended for any deterministic matrix $F_{z_0}$.

**Proof of Lemma 5.5.** Consider the following Hermitian matrix $K_{2n}$ of size $2n \times 2n$

$$K_{2n} = \begin{pmatrix} 0 & \left(\frac{1}{\sqrt{n}}\tilde{Y}_{(n-1)\times n} - F_{z_0}\right)^* \\ \frac{1}{\sqrt{n}}\tilde{Y}_{(n-1)\times n} - F_{z_0} & 0 \end{pmatrix}. $$
Apparently,

\[ K_{2n}^2 = \begin{pmatrix} \frac{1}{\sqrt{n}} \tilde{Y}_{(n-1)\times n} - F_{z_0} & \left( \frac{1}{\sqrt{n}} \tilde{Y}_{(n-1)\times n} - F_{z_0} \right)^* \\ 0 & \frac{1}{\sqrt{n}} \tilde{Y}_{(n-1)\times n} - F_{z_0} \end{pmatrix} \begin{pmatrix} \frac{1}{\sqrt{n}} \tilde{Y}_{(n-1)\times n} - F_{z_0} \\ 0 \end{pmatrix} \].

So to prove Lemma 5.5, it is enough to show that

\[ P \left( \left\| \sum_{i=1}^{2n} g(\lambda_i(K_{2n})) - \mathbb{E} \left( \sum_{i=1}^{2n} g(\lambda_i(K_{2n})) \right) \right\| \geq 2\delta n \right) = O \left( \exp \left( -Cn^{2\delta^2} / K^2 \|g\|_L^2 \right) \right), \]

(5.2)

where \( \lambda_i(K_{2n}) \) are the eigenvalues of \( K_{2n} \).

Next, by following [18], Lemma 1.2, we obtain the following.

Lemma 5.6. The function \( M \mapsto \text{tr}(\frac{1}{\sqrt{n}}M + F) \) of Hermitian matrices \( M = (m_{ij})_{1\leq i,j\leq n} \), where \( F \) is a deterministic Hermitian matrix whose entries may depend on \( n \), is a:

- convex function;
- Lipschitz function of constant bounded by \( 2\|g\|_L \).

We refer the reader to Appendix A for a proof of Lemma 5.6. To deduce (5.2) from Lemma 5.6, we apply the following well-known Talagrand concentration inequality [32].

Lemma 5.7. Let \( D \) be the disk \( \{ z \in \mathbb{C}, |z| \leq K \} \). For every product probability \( \mu \) in \( D^N \), every convex function \( F : \mathbb{C}^N \to \mathbb{R} \) of Lipschitz norm \( \|F\|_L \), and every \( r \geq 0 \),

\[ P(|F - M(F)| \geq r) \leq 4 \exp(-r^2/16K^2\|F\|_L^2), \]

where \( M(F) \) denotes the median of \( F \).

Indeed, let \( F \) be the function \( : \tilde{Y}' \mapsto \text{tr}(g(K_{2n})) = \text{tr}(g(\frac{1}{\sqrt{n}}\tilde{Y}' + F') \) where

\[ \tilde{Y}' = \begin{pmatrix} 0 & \tilde{Y}'_{(n-1)\times n} \\ \tilde{Y}'_{(n-1)\times n} & 0 \end{pmatrix} \]
and
\[
F' = \begin{pmatrix}
0 & -F^*_{z_0} \\
-F_{z_0} & 0
\end{pmatrix}.
\]

Observe that the entries of $\tilde{Y}'$ are supported on $|x| \leq K = 10 \log n$. By Lemma 5.6, $F$ is a convex function with Lipschitz constant bounded by $2\|g\|_L$. The conclusion (5.2) of Lemma 5.5 then follows by applying Lemma 5.7. □

In what follows we will apply Lemma 5.5 for two functions: one gives an almost complete control on the large spectra of $H$, and the other yields a good bound on the number of small spectra of $H$. We will choose $c$ to be a sufficiently small constant, and with room to spare we set
\[
\varepsilon = \delta = \Theta(n^{-c}).
\]

5.8. Concentration of large spectra for i.i.d. matrices. Following [10] and [13], we first apply Lemma 5.5 to the cut-off function $f_\varepsilon(x) := \log(\max(\varepsilon, x))$. Note that $f_\varepsilon(x^2)$ has Lipschitz constant $2\varepsilon^{-1/2}$. Although the function is not convex, it is easy to write it as a difference of two convex functions of Lipschitz constant $O(\varepsilon^{-1/2})$, and so Lemma 5.5 applies because
\[
\delta = \Theta(n^{-c}) \geq C\varepsilon^{1/2}/K/n.
\]

**Theorem 5.9.** We have
\[
P\left(\sum_{\sigma_i^2((1/\sqrt{n})\tilde{Y}_{(n-1)\times n} - F_{z_0}) \in S_\varepsilon} \log \sigma_i \left(\frac{1}{\sqrt{n}}\tilde{Y}_{(n-1)\times n} - F_{z_0}\right) \right)
\]
\[
- \mathbb{E}\left(\sum_{\sigma_i^2(\cdots) \in S_\varepsilon} \log \sigma_i(\cdots)\right) \geq \delta n
\]
\[
= O(\exp(-n^2\delta^2\varepsilon/K^2)) = O(\exp(-n\log^2 n)),
\]
where $S_\varepsilon := \{x \in \mathbb{R}, x \geq \varepsilon\}$.

For short, from now on we set
\[
h_{\varepsilon,\tilde{Y}_{(n-1)\times n}}(z_0) := \frac{1}{n} \mathbb{E}\left(\sum_{\sigma_i^2((1/\sqrt{n})\tilde{Y}_{(n-1)\times n} - F_{z_0}) \in S_\varepsilon} \log \sigma_i \left(\frac{1}{\sqrt{n}}\tilde{Y}_{(n-1)\times n} - F_{z_0}\right)\right).
\]

Serving as the main term, $h_{\varepsilon,\tilde{Y}_{(n-1)\times n}}(z_0)$ will play a key role in our analysis. In the next subsection we apply Lemma 5.5 to another function $f$.

5.10. Concentration of the number of small eigenvalues for i.i.d. matrices. Let $I$ be the interval $[0, \varepsilon]$. We are going to show that the number $N_I$ of the eigenvalues $\lambda_i(H)$ which belong to $I$ is small with very high probability.
It is not hard to construct two functions $f_1, f_2$ such that $(f_1 - f_2) - 1_I$ is nonnegative and supported on an interval of length $\varepsilon/C$, and so that both of $g_1(x) = f_1(x^2)$ and $g_2(x) = f_2(x^2)$ are convex functions of Lipschitz constant $O(\varepsilon^{-1/2})$. (E.g., one may construct $f_1(x), f_2(x)$ in such a way that the even function $g_1(x) = f_1(x^2)$ is identical to 1 on the interval $[-\varepsilon^{1/2}, \varepsilon^{1/2}]$ and being straight concave down from both edges with a slope of $O(\varepsilon^{-1/2})$, while the graph of the function $g_2(x) = f_2(x^2)$ is obtained from that of $g_1(x)$ by replacing its positive part with zero).

Next, by Lemma 5.5 we have
\[
\Pr\left( \left| \sum_{\lambda_i(H)} f_1(\lambda_i(H)) - \mathbb{E}\left( \sum_{\lambda_i(H)} f_1(\lambda_i(H)) \right) \right| \geq \delta n \right) = O(\exp(-n \log^2 n))
\]
and
\[
\Pr\left( \left| \sum_{\lambda_i(H)} f_2(\lambda_i(H)) - \mathbb{E}\left( \sum_{\lambda_i(H)} f_2(\lambda_i(H)) \right) \right| \geq \delta n \right) = O(\exp(-n \log^2 n)).
\]

By the triangle inequality, we thus have
\[
\Pr\left( \left| \sum_{\lambda_i(H)} (f_1 - f_2)(\lambda_i(H)) \right| \geq 2\delta n \right) = O(\exp(-n \log^2 n)).
\]
Because the error-function $f = (f_1 - f_2) - 1_I$ is nonnegative, it follows that with probability $1 - O(\exp(-n \log^2 n))$
\[
\sum_{\lambda_i(H)} 1_I(\lambda_i(H)) + \sum_{\lambda_i(H)} f(\lambda_i(H)) \leq \mathbb{E}\left( \sum_{\lambda_i(H)} (f_1 - f_2)(\lambda_i(H)) \right) + 2\delta n,
\]
and hence
\[
N_I = \sum_{\lambda_i(H)} 1_I(\lambda_i(H)) \leq \mathbb{E}\left( \sum_{\lambda_i(H)} (f_1 - f_2)(\lambda_i(H)) \right) + 2\delta n
\]
\[
\leq 2\mathbb{E}\left( \sum_{\lambda_i(H)} 1_J(\lambda_i(H)) \right) + 2\delta n
\]
\[
\leq 2\mathbb{E}(N_J) + 2\delta n,
\]
where $J$ is the interval $[0, \varepsilon + \varepsilon/C]$ and $N_J$ is the number of eigenvalues of $H$ in $J$. (Strictly speaking, we have to set $J = [-\varepsilon/C, \varepsilon + \varepsilon/C]$. However, as $\lambda_i$ are nonnegative, we can omit its negative interval.)

To exploit the above information furthermore, we apply a result saying that $N_J$ has small expected value (see also [39], Proposition 28 and the references therein).
Lemma 5.11. For all \( J \subset \mathbb{R} \) with \( |J| \geq K^2 \log^2 n/n^{1/2} \), one has
\[
N_J \ll n|J|
\]
with probability \( 1 - \exp(-\omega(\log n)) \). In particular,
\[
\mathbb{E}(N_J) \leq C n |J|,
\]
where \( C \) is a sufficiently large constant.

We remark that this result holds for any deterministic matrix \( F_0 \) in the definition of \( H \). We defer the proof of Lemma 5.11 to Appendix B.

In summary, we have obtained the following result.

Theorem 5.12. With probability \( O(\exp(-n \log^2 n)) \), we have
\[
N_I \geq 2C\varepsilon n + 2\delta n,
\]
where \( N_I \) is the number of \( \sigma_i(\frac{1}{\sqrt{n}} \tilde{Y}_{(n-1) \times n} - F_{z_0}) \) such that \( \sigma_i^2(\frac{1}{\sqrt{n}} \tilde{Y}_{(n-1) \times n} - F_{z_0}) \in [0, \varepsilon] \).

Consequently, it follows from Theorems 5.4 and 5.12 that with probability \( 1 - O(n^{-B}) \) the following holds:
\[
\frac{1}{n} \sum_{\sigma_i(\frac{1}{\sqrt{n}} \tilde{Y}_{(n-1) \times n} - F_{z_0}) \in [0, \varepsilon]} \log \sigma_i \left( \frac{1}{\sqrt{n}} \tilde{Y}_{(n-1) \times n} - F_{z_0} \right) = O((\varepsilon + \delta) \log n)
\]
\[
= O(n^{-c} \log n).
\]

Thus, combining with Theorem 5.9, we infer the following.

Theorem 5.13. Let \( z_0 \) be fixed, and let \( B \) be a positive constant. Then the following holds with probability \( 1 - O(n^{-B}) \):
\[
\left| \frac{1}{n} \log \left| \det \left( \frac{1}{\sqrt{n}} \tilde{Y}_{(n-1) \times n} - F_{z_0} \right) \right| - h_{\varepsilon, \tilde{Y}_{(n-1) \times n}}(z_0) \right| \leq 2\delta + O(n^{-c} \log n)
\]
\[
= O(n^{-c} \log n),
\]
where the implied constants depend on \( B \).

5.14. Asymptotic formula for \( h_{\varepsilon, \tilde{Y}_{(n-1) \times n}}(z_0) \). We next claim that
\[
\frac{1}{n} \log |\det(\frac{1}{\sqrt{n}} \tilde{Y}_{(n-1) \times n} - F_{z_0})|\]
also converges to the corresponding part of the circular law, and so gives an asymptotic formula for \( h_{\varepsilon, \tilde{Y}_{(n-1) \times n}}(z_0) \).

Theorem 5.15. For almost all \( z_0 \), the following holds with probability one:
\[
(5.3) \quad \frac{1}{n} \log \left| \det \left( \frac{1}{\sqrt{n}} \tilde{Y}_{(n-1) \times n} - F_{z_0} \right) \right| - \int_C \log |w - z_0| \, d\mu_{\text{cir}}(w) = o(1).
\]
Note that this result is more or less the circular law for random matrices with i.i.d. entries. To prove it we simply rely on [36].

**Proof of Theorem 5.15.** We first pass to \(
\tilde{Y}
\)

\[
\tilde{Y} = \begin{pmatrix}
\tilde{y}_{22} - \tilde{y}_{21} & \cdots & \tilde{y}_{2n} - \tilde{y}_{21} \\
\tilde{y}_{32} - \tilde{y}_{31} & \cdots & \tilde{y}_{3n} - \tilde{y}_{31} \\
\vdots & \ddots & \vdots \\
\tilde{y}_{n2} - \tilde{y}_{n1} & \cdots & \tilde{y}_{nn} - \tilde{y}_{n1}
\end{pmatrix},
\]

where \(\tilde{y}_{ij}\) are i.i.d. copies of \(\tilde{y}\).

As \(\det\left(\frac{1}{\sqrt{n}} \tilde{y}_{(n-1)\times n} - F_{z_0}\right) = \sqrt{n} \det\left(\frac{1}{\sqrt{n}} \tilde{y} - z_0 I_{n-1}\right)\), it is enough to prove the claim for \(\det(\frac{1}{\sqrt{n}} \tilde{y} - z_0 I_{n-1})\).

View \(\tilde{Y}\) as a sum of the matrix \((\tilde{y}_{ij})_{2\leq i,j\leq n}\) and \(R\), the \((n-1)\times (n-1)\) matrix formed by \((-\tilde{y}_{1i}, \ldots, -\tilde{y}_{1n})\) for \(2 \leq i \leq n\). Because \(R\) has rank one and the average square of its entries \(\frac{1}{n-1} \sum_i \tilde{y}_{1i}^2\) is bounded almost surely (with respect to \(\tilde{y}_{21}, \ldots, \tilde{y}_{n1}\), [36], Corollary 1.15, applied to \(\tilde{Y}\) implies that the ESD of \(\frac{1}{\sqrt{n}} \tilde{Y}\) converges almost surely to the circular law.

Finally, thanks to [36], Theorem 1.20, for almost all \(z_0\) the following holds with probability one:

\[
\frac{1}{n} \log |\det\left(\frac{1}{\sqrt{n}} \tilde{y} - z_0 I_{n-1}\right)| - \int_C \log |w - z_0| d\mu_{\text{cir}}(w) = o(1). \tag{5.4}
\]

Theorems 5.13 and 5.15 immediately imply that for almost all \(z_0\),

\[
h_{\epsilon, \tilde{y}_{(n-1)\times n}}(z_0) - \int_C \log |w - z_0| d\mu_{\text{cir}}(w) = o(1). \tag{5.5}
\]

By substituting (5.4) back into Theorem 5.9, we have

\[
P\left(\frac{1}{n} \sum_{\sigma^2((1/\sqrt{n})\tilde{y}_{(n-1)\times n} - F_{z_0}) \in S_\epsilon} \log \sigma_i\left(\frac{1}{\sqrt{n}} \tilde{y}_{(n-1)\times n} - F_{z_0}\right) \geq \delta + o(1)\right) = O(exp(-n \log^2 n)).
\]

6. Large concentration for \(\tilde{X}\), proof of Theorem 1.10. In this section we will apply the transference principle of Lemma 2.3 to pass the results of Section 5 back to \(\tilde{X}\). Our treatment here is similar to [9], Section 4.
By Lemma 2.3 and (5.5), conditioning on \( \bar{Y} \in \bar{D}_n \) we have

\[
\mathbb{P}\left( \sum_{\sigma_i^2(1/\sqrt{n})\bar{Y}_{(n-1)\times n} - F_{z_0}) \in S_{c+\alpha^{-2}} \right) \log \sigma_i \left( \frac{1}{\sqrt{n}} \bar{Y}_{(n-1)\times n} - F_{z_0} \right) \geq \delta + o(1) |\bar{Y} \in \bar{D}_n \right)
\]

(6.1)

\[
= O(n^{10n} \exp(-n \log^2 n)) = O(\exp(-n \log^2 n/2)).
\]

Next, for each \( \bar{Y} \in \bar{D}_n \) we will compare the singular values of \( \frac{1}{\sqrt{n}} \bar{Y}_{(n-1)\times n} - F_{z_0} \) with those of \( \sqrt{n} \bar{X}_{(n-1)\times n} - F_{z_0} \), where \( \bar{X} \) is determined by \( \Phi(\frac{1}{n} \bar{Y}) \), that is, \( \bar{x}_{ij} = \frac{1}{\sqrt{n}} \bar{y}_{ij} \) for all \( 2 \leq i, j \leq n \).

By definition, as \( \bar{Y} \in \bar{D}_n \), we have \( |\frac{1}{\sqrt{n}} \bar{y}_{i1} - \bar{x}_{i1}| \leq n^{-4} \), and so the operator norm of the difference matrix is bounded by

\[
\left\| \left( \frac{1}{\sqrt{n}} \bar{Y}_{(n-1)\times n} - F_{z_0} \right) - (\sqrt{n} \bar{X}_{(n-1)\times n} - F_{z_0}) \right\| \leq \frac{1}{n^2}.
\]

This leads to a similar bound for the singular values for every \( i \) (see, e.g., [20])

(6.2) \[
\left| \sigma_i \left( \frac{1}{\sqrt{n}} \bar{Y}_{(n-1)\times n} - F_{z_0} \right) - \sigma_i (\sqrt{n} \bar{X}_{(n-1)\times n} - F_{z_0}) \right| \leq \frac{1}{n^2}.
\]

Notice furthermore that, conditioning on \( \bar{Y} \in \bar{D}_n \), \( \Phi(\frac{1}{n} \bar{Y}) \) is uniformly distributed on the set \( S_n \) of bounded doubly stochastic matrices \( \bar{X} \). Thus, with a slight modification to \( \varepsilon \) by an amount of \( n^{-2} \) [thus the order of \( \varepsilon \) remains \( \Theta(n^{-e}) \)], we obtain from (6.1) the following upper tail bound with respect to \( \bar{X} \):

\[
\mathbb{P}\left( \sum_{\sigma_i^2(\sqrt{n})\bar{X}_{(n-1)\times n} - F_{z_0}) \in S_{c+\alpha^{-2}} \right) \log \sigma_i (\sqrt{n} \bar{X}_{(n-1)\times n} - F_{z_0}) \geq \delta + o(1) \right) = O(\exp(-n \log^2 n/2)).
\]

Also, we obtain a similar probability bound for the lower tail

\[
\mathbb{P}\left( \sum_{\sigma_i^2(\sqrt{n})\bar{X}_{(n-1)\times n} - F_{z_0}) \in S_{c-\alpha^{-2}} \right) \log \sigma_i (\sqrt{n} \bar{X}_{(n-1)\times n} - F_{z_0}) \leq -\delta + o(1) \right) = O(\exp(-n \log^2 n/2)).
\]
Notice that these bounds hold for any \( \varepsilon = \Theta(n^{-c}) \). By gluing them together we infer the following variant of (6.1).

**Theorem 6.1.** With respect to \( \tilde{X} \) we have

\[
P\left( \frac{1}{n} \sum_{\sigma_i^2(\sqrt{n}\tilde{X}(n-1)_{n} \times F_{z_0}) \in S_{\varepsilon}} \log \sigma_i(\sqrt{n}\tilde{X}(n-1)_{n} \times F_{z_0}) - \int_C \log |w - z_0| \, d\mu_{\text{cir}}(w) \geq \delta + o(1) \right) = O(\exp(-n \log^2 n/2)).
\]

Next, conditioning on \( \tilde{Y} \in \tilde{D}_n \), by Theorem 5.12 and Lemma 2.3, with probability \( O(n^{10} \exp(-n \log^2 n)) = O(\exp(-n \log^2 n/2)) \) we have

\[
N_I \geq 2C\varepsilon n + 2\delta n,
\]

where \( N_I \) is the number of \( \sigma_i(\frac{1}{\sqrt{n}}\tilde{Y}(n-1)_{n} \times F_{z_0}) \) such that \( \sigma_i^2(\frac{1}{\sqrt{n}}\tilde{Y}(n-1)_{n} \times F_{z_0}) \in [0, \varepsilon] \).

Because \( \Phi(\frac{1}{n}\tilde{Y}) \) is uniformly distributed on the set \( \tilde{S}_n \) conditioning on \( \tilde{Y} \in \tilde{D}_n \), and also because of (6.2), we imply the following.

**Theorem 6.2.** With probability \( O(\exp(-n \log^2 n)) \) with respect to \( \tilde{X} \), we have

\[
N_I \geq 2C(\varepsilon + \frac{1}{n^2}) n + 2\delta n,
\]

where \( N_I \) is the number of \( \sigma_i(\sqrt{n}\tilde{X}(n-1)_{n} \times F_{z_0}) \) such that \( \sigma_i^2(\sqrt{n}\tilde{X}(n-1)_{n} \times F_{z_0}) \in [0, \varepsilon] \).

We now gather the ingredients together to complete the proof of our main result.

**Proof of Theorem 1.10 for \( \tilde{X} \).** By Theorems 5.2 and 6.2, we have that

\[
P\left( \frac{1}{n} \sum_{\sigma_i^2(\sqrt{n}\tilde{X}(n-1)_{n} \times F_{z_0}) \in [0, \varepsilon]} \log \sigma_i(\sqrt{n}\tilde{X}(n-1)_{n} \times F_{z_0}) = O((\varepsilon + \delta) \log n) \right)
\]

\[
= 1 - O(n^{-3}).
\]

A combination of this fact with Theorem 6.1 implies that for almost all \( z_0 \),

\[
P\left( \frac{1}{n} \log |\det(\sqrt{n}\tilde{X}(n-1)_{n} \times F_{z_0}) - \int_C \log |w - z_0| \, d\mu_{\text{cir}}(w) | = o(1) \right)
\]

\[
= 1 - O(n^{-3}).
\]
Hence, by (5.1),
\[ P\left( \frac{1}{n} \log |\det(\sqrt{n}\tilde{X} - z_0I_{n-1})| - \int_{\mathbb{C}} \log |w - z_0| \, d\mu_{cir}(w) \right) = o(1) \]
completing the proof. □

APPENDIX A: PROOF OF LEMMA 5.6

The main goal of this section is to justify Lemma 5.6. Although our proof is identical to [18], Theorem 1.1 and [18], Corollary 1.8, let us present it here for the sake of completeness.

A.1. Convexity. For simplicity, we first show that the function \( M \mapsto \text{tr}(g(M + F)) \) is convex. It then follows that the function \( M \mapsto \text{tr}(\frac{1}{\sqrt{n}}M + F) \) is also convex.

For any Hermitian matrices \( U \) and \( V \)
\[ g(V + F) - g(U + F) = \int_0^1 Dg(U + F + \eta(V - U)) \hat{z}(V - U) \, d\eta \]

where
\[ Dg(U + F)\hat{z}(V) = \lim_{\varepsilon \to 0} \varepsilon^{-1}(g(U + F + \varepsilon V) - g(U + F)) \]

For polynomial functions \( g \), the noncommutative derivation \( D \) can be computed, and one finds in particular that for any \( p \in \mathbb{N} \),
\[(V + F)^p - (U + F)^p \]
\[ = \int_0^1 \left( \sum_{k=0}^{p-1} (U + F + \eta(V - U))^k(V - U) \right. \]
\[ \times \left. (U + F + \eta(V - U))^{p-k-1} \right) d\eta. \]

(A.1)

For such a polynomial function, by taking the trace and using \( \text{tr}(AB) = \text{tr}(BA) \), one deduces that
\[ \text{tr}((U + F)^p) - \text{tr}\left( \left( \frac{U + V}{2} + F \right)^p \right) \]
\[ = p \int_0^1 \text{tr}\left( \left( \frac{U + V}{2} + F + \eta \frac{U - V}{2} \right)^{p-1} \frac{U - V}{2} \right) \, d\eta, \]
\[ \text{tr}((V + F)^p) - \text{tr}\left( \left( \frac{U + V}{2} + F \right)^p \right) \]

(A.2)
RANDOM DOUBLY STOCHASTIC MATRICES: THE CIRCULAR LAW

\[ (A.3) \]
\[ = p \int_0^1 \text{tr} \left( \left( \frac{U + V}{2} + F - \eta \frac{U - V}{2} \right)^{p-1} \frac{V - U}{2} \right) d\eta. \]

It follows from (A.1), (A.2) and (A.3) that

\[ \Delta := \text{tr}((U + F)^p) + \text{tr}((V + F)^p) - 2\text{tr} \left( \left( \frac{U + V}{2} + F \right)^p \right) \]
\[ (A.4) \]
\[ = p \frac{p-2}{2} \sum_{k=0}^{p-2} \int_0^1 \int_0^1 \eta d\eta d\theta \text{tr}((U - V)Z_{\eta,\theta}^k(U - V)Z_{\eta,\theta}^{p-2-k}) \]

with
\[ Z_{\eta,\theta} := \frac{U + V}{2} + F - \frac{U - V}{2} + \eta \theta(U - V). \]

Next, for fixed \( \eta, \theta \in [0, 1]^2 \), and fixed \( U, V, F \) Hermitian matrices, \( Z_{\eta,\theta} \) is also Hermitian, and so we can find a unitary matrix \( U_{\eta,\theta} \) and a diagonal matrix \( D_{\eta,\theta} \) with real diagonal entries \( \lambda_{\eta,\theta}(1), \ldots, \lambda_{\eta,\theta}(n) \) so that
\[ Z_{\eta,\theta} = U_{\eta,\theta}D_{\eta,\theta}U_{\eta,\theta}^* \].

Let \( W_{\eta,\theta} = U_{\eta,\theta} = U_{\eta,\theta}^*(U - V)U_{\eta,\theta} \). Then
\[ \Delta = \frac{p}{2} \sum_{k=0}^{p-2} \int_0^1 \int_0^1 \eta d\eta d\theta \text{tr}(W_{\eta,\theta}D_{\eta,\theta}^kW_{\eta,\theta}D_{\eta,\theta}^{p-2-k}) \]
\[ (A.5) \]
\[ = \frac{p}{2} \sum_{k=0}^{p-2} \int_0^1 \int_0^1 \eta d\eta d\theta \sum_{k=0}^{p-2} \sum_{1 \leq i,j \leq n} \lambda_{\eta,\theta}^k(i)\lambda_{\eta,\theta}^{p-2-k}(j)|W_{\eta,\theta}(ij)|^2. \]

But
\[ \sum_{k=0}^{p-2} \lambda_{\eta,\theta}^k(i)\lambda_{\eta,\theta}^{p-2-k}(j) = \frac{\lambda_{\eta,\theta}^{p-1}(i) - \lambda_{\eta,\theta}^{p-1}(j)}{\lambda_{\eta,\theta}(i) - \lambda_{\eta,\theta}(j)} \]
\[ = (p - 1) \int_0^1 (\alpha \lambda_{\eta,\theta}(j) + (1 - \alpha) \lambda_{\eta,\theta}(i))^{p-2} d\alpha. \]

Hence, substituting into (A.5) gives
\[ \Delta = \frac{1}{2} \sum_{1 \leq i,j \leq n} \int_0^1 \int_0^1 d\eta \eta d\theta |W_{\eta,\theta}(ij)|^2 \]
\[ (A.6) \]
\[ \times g''(\alpha \lambda_{\eta,\theta}(j) + (1 - \alpha) \lambda_{\eta,\theta}(i)) \geq 0 \]

for the polynomial \( g(x) = x^p \).
Now, with $U, V, F$ being fixed, the eigenvalues $\lambda_{\eta, \theta}(1), \ldots, \lambda_{\eta, \theta}(n)$ and the entries of $W_{\eta, \theta}$ are uniformly bounded. Hence, by Runge’s theorem, we can deduce by approximation that (A.6) holds for any twice continuously differentiable function $g$. As a consequence, for any such convex function we have $g'' \geq 0$ and

$$\Delta = \text{tr}(g(U + F)) + \text{tr}(g(V + F)) - 2\text{tr}\left(g\left(\frac{U + V}{2} + F\right)\right) \geq 0.$$  

A.2. Boundedness. Now we show that the function $M \mapsto \text{tr}(g\left(\frac{1}{\sqrt{n}} M + F\right))$ has Lipschitz constant bounded by $2\|g\|_L$.

First, for any bounded continuously differentiable function $g$ we will show that

$$\sum_{1 \leq i,j \leq n} \left(\frac{d_{\mathcal{R}(x_{ij})}}{\sqrt{n}} \text{tr}\left(g\left(\frac{1}{\sqrt{n}} M + F\right)\right)\right)^2 + \sum_{1 \leq i,j \leq n} \left(\frac{d_{\mathcal{R}(x_{ij})}}{\sqrt{n}} \text{tr}\left(g\left(\frac{1}{\sqrt{n}} M + F\right)\right)\right)^2 \leq 4\|g\|_L^2,$$

We can verify that

$$d_{\mathcal{R}(x_{ij})} \text{tr}\left(g\left(\frac{1}{\sqrt{n}} M + F\right)\right) = \frac{1}{\sqrt{n}} \text{tr}\left(g'\left(\frac{1}{\sqrt{n}} M + F\right) \Delta_{ij}\right),$$

where $\Delta_{ij}(k l) = 1$ if $k l = i j$ or $j i$ and zero otherwise.

Indeed, (A.7) is a consequence of (A.1) for polynomial functions, and it can be extended for bounded continuously differentiable functions by approximations. In other words, we have

$$d_{\mathcal{R}(x_{ij})} \text{tr}\left(g\left(\frac{1}{\sqrt{n}} M + F\right)\right) = \begin{cases} \frac{1}{\sqrt{n}} g'\left(\frac{1}{\sqrt{n}} M + F\right)(i j) + g'\left(\frac{1}{\sqrt{n}} M + F\right)(j i), & i \neq j; \\ \frac{1}{\sqrt{n}} g'\left(\frac{1}{\sqrt{n}} M + F\right)(i i), & i = j. \end{cases}$$

Hence,

$$\sum_{i,j} \left(\frac{d_{\mathcal{R}(x_{ij})}}{\sqrt{n}} \text{tr}\left(g\left(\frac{1}{\sqrt{n}} M + F\right)\right)\right)^2 \leq 2 \sum_{i,j} \left|g'\left(\frac{1}{\sqrt{n}} M + F\right)(i j)\right|^2$$

$$= \frac{2}{n} \text{tr}\left(g'\left(\frac{1}{\sqrt{n}} M + F\right)g'\left(\frac{1}{\sqrt{n}} M + F\right)^*\right).$$

But if $\lambda_1, \ldots, \lambda_n$ denote the eigenvalues of $\frac{1}{\sqrt{n}} M + F$, then

$$\text{tr}\left(g'\left(\frac{1}{\sqrt{n}} M + F\right)g'\left(\frac{1}{\sqrt{n}} M + F\right)^*\right) = \frac{1}{n} \sum (\lambda_i)^2 \leq \|g'\|_\infty^2.$$
Thus we have
\[
\sum_{i,j} \left( d_{\mathcal{R}(x_{ij})} \text{tr} \left( g \left( \frac{1}{\sqrt{n}} M + F \right) \right) \right)^2 \leq 2 \|g'\|_\infty^2.
\]

The same argument applies for derivatives with respect to \(\mathcal{I}(x_{ij})\), and so by integration by parts and by the Cauchy–Schwarz inequality,
\[
\left| \text{tr} \left( g \left( \frac{1}{\sqrt{n}} U + F \right) \right) - \text{tr} \left( g \left( \frac{1}{\sqrt{n}} V + F \right) \right) \right| \leq 2 \|g\|_L \|U - V\|
\]
for any \(U\) and \(V\).

Observe that the last result for bounded continuously differentiable functions naturally extends to Lipschitz functions by approximation, completing the proof.

APPENDIX B: PROOF OF LEMMA 5.11

Note that if \(F_{z_0}\) vanishes, then Lemma 5.11 is just [39], Proposition 28; see also [2]. We show that the method there extends easily to any deterministic \(F_{z_0}\).

Assume for contradiction that
\[
|N_J| \geq Cn|J|
\]
for some large constant \(C\) to be chosen later. We will show that this will lead to a contradiction with high probability.

We will control the eigenvalue counting function \(N_J\) via the Stieltjes transform
\[
s(z) := \frac{1}{n} \sum_{j=1}^n \frac{1}{\lambda_j(H) - z}.
\]

Fix \(J\) and let \(x\) be the midpoint of \(J\). Set \(\eta := |J|/2\) and \(z := x + i\eta\), and we then have
\[
\mathcal{I}(s(z)) \geq \frac{4}{5} \frac{N_J}{\eta n}.
\]

Hence,
\[
\mathcal{I}(s(z)) \gg C.
\]

Next, with \(H' := (\frac{1}{\sqrt{n}} \Phi(\tilde{Y}) - F_{z_0})(\frac{1}{\sqrt{n}} \Phi(\tilde{Y}) - F_{z_0})^* = \frac{1}{n} MM^*\) where \(M := \Phi(\tilde{Y}) - \sqrt{n} F_{z_0}\), we have (see also [2], Chapter 11)
\[
s(z) = \frac{1}{n} \sum_{k \leq n} h'_{kk} - z - a^*_k (H' - zI)^{-1} a_k,
\]
where \(h'_{kk}\) is the \(kk\) entry of \(H'\); \(H'_k\) is the \(n - 1\) by \(n - 1\) matrix with the \(k\)th row and \(k\)th column of \(H'\) removed; and \(a_k\) is the \(k\)th column of \(H'\) with the \(k\)th entry removed.
Note that $\Im(\frac{1}{z}) \leq \frac{1}{\Im(z)}$, one concludes from (B.1) that
\[
\frac{1}{n} \sum_{k \leq n} \frac{1}{|\eta + \Im(a_{k}^*(H'_k - zI)^{-1}a_k)|} \gg C.
\]

By the pigeonhole principle, there exists $k$ such that
\[
(B.2) \quad \frac{1}{|\eta + \Im(a_{k}^*(H'_k - zI)^{-1}a_k)|} \gg C.
\]

Fix such $k$, note that
\[
a_k = \frac{1}{n} M_k r_k^* \quad \text{and} \quad H'_k = \frac{1}{n} M_k M_k^*,
\]
where $r_k = r_k(M)$ and $M_k$ is the $(n-1) \times n$ matrix formed by removing $r_k(M)$ from $M$. Thus if we let $v_1 = v_1(M_k), \ldots, v_{n-1} = v_{n-1}(M_k)$ and $u_1 = u_1(M_k), \ldots, u_{n-1} = u_{n-1}(M_k)$ be the orthogonal systems of left and right singular vectors of $M_k$, and let $\lambda_j = \lambda_j(H'_k) = \frac{1}{n} \sigma^2_j(M_k)$ be the associated eigenvalues, one has
\[
a_k^*(H'_k - zI)^{-1}a_k = \sum_{1 \leq j \leq n-1} \frac{|a_k^* v_j|^2}{\lambda_j - z}.
\]

Thus
\[
\Im(a_k^*(H'_k - zI)^{-1}a_k) \geq \eta \sum_{1 \leq j \leq n-1} \frac{|a_k^* v_j|^2}{\eta^2 + |\lambda_j - x|^2}.
\]

We conclude from (B.2) that
\[
\sum_{1 \leq j \leq n-1} \frac{|a_k^* v_j|^2}{\eta^2 + |\lambda_j - x|^2} \ll \frac{1}{C \eta}.
\]

Note that $a_k^* v_j$ can be written as
\[
a_k^* v_j = \frac{\sigma_j(M_k)}{n} r_k u_j.
\]

Next, from the Cauchy interlacing law, one can find an interval $L \subset \{1, \ldots, n-1\}$ of length
\[
|L| \gg C \eta n
\]
such that $\lambda_j \in L$. We conclude that
\[
\sum_{j \in L} \frac{\sigma_j^2}{n^2} |r_k u_j|^2 \ll \frac{\eta}{C}.
\]

Since $\lambda_j \in J$, one has $\sigma_j = \Theta(\sqrt{n})$, and thus
\[
\sum_{j \in L} |r_k u_j|^2 \ll \frac{\eta m}{C}.
\]
The LHS can be written as $\|\pi_V(r^*_k)\|^2$, where $V$ is the span of the eigenvectors $u_j$ for $j \in L$, and $\pi_V(\cdot)$ is the projection onto $V$. But from Talagrand’s inequality for distance (Lemma B.1 below), we see that this quantity is $\gg \eta n$ with very high probability, giving the desired contradiction.

**Lemma B.1.** Assume that $V \subset \mathbb{C}^n$ is a subspace of dimension $\dim(V) = d \leq n - 10$. Let $f$ be a fixed vector (whose coordinates may depend on $n$). Let $y = (0, y_2, \ldots, y_n)$, where $y = \tilde{y}_i - 1$ and $\tilde{y}_i$ are i.i.d. copies of $\tilde{y}$ defined from (2.2). Let $\sigma = \Theta(1)$ denote the standard deviation of $\tilde{y}$ and $K = 10 \log n$ denote the upper bound of $\tilde{y}$, and then for any $t > 0$ we have

$$P_y(\pi_V(y + f) \geq \sqrt{2\sigma\sqrt{d}/2 - O(K) - t}) \geq 1 - O\left(\exp\left(-\frac{t^2}{16K^2}\right)\right).$$

We now give a proof of Lemma B.1. It is clear that the function $(y_2, \ldots, y_n) \mapsto \pi_V(y + f)$ is convex and 1-Lipschitz. Thus by Theorem 5.7 we have

$$P_y(|\pi_V(y + f) - M(\pi_V(y + f))| \geq t) = O(\exp(-16t^2/K^2)).$$

(B.3)

We see that

$$P_y, y'(|\pi_V(y + f) + \pi_V(y' + f) - 2M(\pi_V(y + f))| \leq 2t)$$

(B.4)

$$= (1 - O(\exp(-16t^2/K^2)))^2$$

$$= 1 - O(\exp(-16t^2/K^2)),$$

where $y'$ is an independent copy of $y$.

On the other hand, by the triangle inequality

$$\pi_V(y + f) + \pi_V(y' + f) \geq \pi_V(y - y').$$

Applying Talagrand’s inequality once more for the random vector $y - y'$ (see, e.g., [38], Lemma 68), we see that

$$P_y(y'(|\pi_V(y - y') - \sqrt{2\sigma\sqrt{d}}| \geq t) = O(\exp(-t^2/16K^2)).$$

Thus,

$$P_y, y'(|\pi_V(y) + \pi_V(y') \geq \sqrt{2\sigma\sqrt{d}} - t) = 1 - O(\exp(-t^2/16K^2)).$$

By comparing with (B.4), we deduce that

$$M(\pi_V(y + f)) \geq \sqrt{1/2\sigma\sqrt{d}} - O(K).$$

Substituting this bound back into (B.4), we obtain the one-sided estimate as desired.
