GROUPS OF PRIME DEGREE AND THE BATEMAN–HORN CONJECTURE

GARETH A. JONES AND ALEXANDER K. ZVONKIN

Abstract. As a consequence of the classification of finite simple groups, the classification of permutation groups of prime degree is complete, apart from the question of when the natural degree \((q^n - 1)/(q - 1)\) of \(\mathrm{PSL}_n(q)\) is prime. We present heuristic arguments and computational evidence based on the Bateman–Horn Conjecture to support a conjecture that for each prime \(n \geq 3\) there are infinitely many primes of this form, even if one restricts to prime values of \(q\). Similar arguments and results apply to the parameters of the simple groups \(\mathrm{PSL}_n(q), \mathrm{PSU}_n(q)\) and \(\mathrm{PSp}_{2n}(q)\) which arise in the work of Dixon and Zalesskii on linear groups of prime degree.

1. Permutation groups of prime degree

One of the oldest problems in Group Theory is to classify the permutation groups of prime degree, originally studied in terms of the solution of polynomial equations of prime degree. Let \(G\) be a transitive permutation group of prime degree \(p\). In 1831 Galois \([20]\) proved that \(G\) is solvable if and only if \(G\) is (isomorphic to) a subgroup of the 1-dimensional affine group
\[
\mathrm{AGL}_1(p) = \{ t \mapsto at + b \mid a, b \in \mathbb{F}_p, a \neq 0 \} \cong C_p \rtimes C_{p-1}
\]
containing the translation subgroup \(\{ t \mapsto t+b \} \cong C_p\). There is one such group \(G\) for each \(d\) dividing \(p-1\), namely
\[
\{ t \mapsto at + b \mid a, b \in \mathbb{F}_p, a^d = 1 \} \cong C_p \rtimes C_d.
\]
In 1906 Burnside ([8], [9, §251]) proved that if \(G\) is nonsolvable then \(G\) is 2-transitive. In this case \(G\) has a unique minimal normal subgroup \(S \neq 1\) which is simple and also 2-transitive, with centraliser \(C_G(S) = 1\), so that \(G \leq \text{Aut} S\). This reduces the problem to studying nonabelian simple groups \(S\) of degree \(p\) and their automorphism groups. The classification of finite simple groups (announced around 1980) implies a classification of those with 2-transitive actions (see [10] or [16], for example). Most of these have composite degree; those of prime degree are as follows:

a) \(S = A_p, G = S_p\), for primes \(p \geq 5\);
b) \(S = \mathrm{PSL}_n(q) \leq G \leq \mathrm{PGL}_n(q) = \mathrm{PGL}_n(q) \rtimes \text{Gal} \mathbb{F}_q\) in cases where the natural degree \(m := (q^n - 1)/(q - 1)\) of these groups is prime;
c) \(S = \mathrm{PSL}_2(11), M_{11}\) and \(M_{23}\) for \(p = 11, 11\) and 23.

In (b) the groups act on the \(m\) points (or \(m\) points and hyperplanes if \(n \geq 3\)) of the projective geometry \(\mathbb{P}^{n-1}(\mathbb{F}_q)\) for a prime power \(q\). In (c), \(\text{PSL}_2(11)\) acts on the 11 cosets of a subgroup \(H \cong A_5\) (two conjugacy classes, giving two actions, equivalent to those on the vertices and cells of the hendecachoron or 11-cell, a nonorientable 4-polytope discovered independently by Grünbaum [22]...
and Coxeter [11]; see also [26]); $M_{11}$ and $M_{23}$ are Mathieu groups, acting on block designs with 11 and 23 points.

Unfortunately, this result does not tell us when the degree $m$ in (b) is prime. Indeed, it is unknown whether there are finitely or infinitely many such ‘projective primes’, as we will call them.

**Open Problem:** In (b), is the degree

$$m = \frac{q^n - 1}{q - 1} = 1 + q + q^2 + \cdots + q^{n-1} \quad (q \text{ a prime power})$$

prime in finitely or infinitely many cases?

If $n = 2$ the projective primes $m$ are the Fermat primes $1 + 2^e$, $e = 2^f$; the only known examples are 3, 5, 17, 257, 65537 for $f \leq 4$. If $q = 2$ the primes $m$ are the Mersenne primes $2^n - 1$, $n$ prime; at the time of writing, 51 examples $3, 7, 31, \ldots, 2^{82,589,933} - 1$ are known. It is widely conjectured that there are no further Fermat primes, but infinitely many Mersenne primes. These are very old and difficult problems; with nothing new to say about them, we will assume from now on that $n, q \geq 3$.

Our main conjecture is that there are infinitely many projective primes. The goal of this note is to present heuristic arguments and computational evidence to support this conjecture. See [29] for further details, [28] for applications to dessins d’enfants (maps on surfaces representing curves defined over algebraic number fields), and [30] for a similar problem involving block designs.

2. Conjectures

If a polynomial $f(t) \in \mathbb{Z}[t]$ takes infinitely many prime values for $t \in \mathbb{N}$ then clearly

• its leading coefficient is positive,
• it is irreducible in $\mathbb{Z}[t]$, and
• it is not identically zero modulo any prime.

In 1857 Bunyakovsky, the discoverer of the infinite-dimensional form of the Cauchy–Schwarz inequality, conjectured in [6] that these conditions are also sufficient. (The last condition is needed to exclude cases like $t^2 + t + 2$, which is irreducible but takes only even values.) The case $\deg f = 1$ is true: this is Dirichlet’s Theorem on primes in an arithmetic progression (see [5, §5.3]). No other case is proved, not even $t^2 + 1$, studied by Euler [15] and Landau. Writing $q = p^e$ we require the result for $f(t) = 1 + t + \cdots + t^{(n-1)e}$, but with the extra condition that $t$ should also be prime.

Schinzel’s Hypothesis H [40] deals with this restriction by extending Bunyakovsky’s conjecture to finite sets of polynomials $f_1, \ldots, f_k$ simultaneously taking prime values infinitely often. An obvious necessary condition is that each $f_i$ should satisfy the first two Bunyakovsky conditions, while the third is that $f(t) := \prod_{i=1}^k f_i(t)$ should not be identically zero modulo any prime. For example, $t(t + 1)$ is identically zero mod (2), while $t(t + 2)$ is not. It is conjectured that these conditions are also sufficient, but as in the case of the Bunyakovsky Conjecture this has been proved only in the case $k = 1$, $\deg f_1 = 1$. (However, see [41] for recent evidence in support of Hypothesis H.)

In addition to cases with $k = 1$, such as the Euler–Landau problem, conjectures which would follow from a proof of Hypothesis H include

• $f_1 = t$, $f_2 = t + 2$, the twin primes conjecture;
• \( f_1 = t, f_2 = 2t + 1 \), the Sophie Germain primes conjecture;
• \( f_1 = t, f_2 = 1 + t^e + t^{2e} + \cdots + t^{(e-1)e} \) for fixed \( e \) and \( n \), particular cases of our projective primes conjecture, provided \( f_2 \) is irreducible (see Section 3).

Remark 2.1 (Hypothesis \( H_0 \)). In the same paper [40], the authors formulate an apparently weaker conjecture \( H_0 \): under the same conditions as above, the values \( f_1(t), \ldots, f_k(t) \) are all prime for at least one positive integer \( t \). It turns out, however, that \( H_0 \) implies \( H \), and this fact is trivial! It suffices to consider the sets of polynomials \( f_1(t+c), \ldots, f_k(t+c) \) for constants \( c \in \mathbb{N} \), and to note that, according to \( H_0 \), the values of the polynomials in each of the sets are all prime for at least one integer \( t > 0 \).

In 1962 Bateman and Horn [3] proposed a quantified version of Schinzel’s Hypothesis \( H \) which, if proved, would imply all the above conjectures (see [1] for an excellent survey).

Conjecture 2.2 (The Bateman–Horn Conjecture (BHC)). If distinct polynomials \( f_1, \ldots, f_k \) satisfy the above conditions, and \( Q(x) \) is the number of positive integers \( t \leq x \) such that \( f_1(t), \ldots, f_k(t) \) are all prime, then

\[
Q(x) \sim E(x) := \frac{C}{\prod_{i=1}^{k} \deg f_i} \int_{2}^{x} \frac{dt}{(\ln t)^k} \quad \text{as} \quad x \to \infty,
\]

where

\[
C = C(f_1, \ldots, f_k) := \prod_{\text{prime } r} \left( 1 - \frac{1}{r} \right)^{-k} \left( 1 - \frac{\omega_f(r)}{r} \right)
\]

with the product over all primes \( r \), and \( \omega_f(r) \) is the number of solutions in \( \mathbb{F}_r \) of \( f(t) = 0 \).

The infinite product converges to a limit \( C > 0 \) (see [1] for a proof), and \( \int_{2}^{x} \frac{dt}{(\ln t)^k} \) diverges for each \( k \geq 1 \), so \( E(x) \to \infty \) with \( x \); thus \( f_1(t), \ldots, f_k(t) \) are simultaneously prime for infinitely many \( t \) provided the conjecture is true. However, it is proved only in the case of Dirichlet’s Theorem. Since

\[
\int_{2}^{x} \frac{dt}{(\ln t)^k} = \frac{x}{(\ln x)^k} + O\left( \frac{x}{(\ln x)^{k+1}} \right),
\]

there is an alternative form

\[
Q(x) \sim H(x) := \frac{C}{\prod_{i=1}^{k} \deg f_i} \cdot \frac{x}{(\ln x)^k} \quad \text{as} \quad x \to \infty
\]

for the estimate, which can be more convenient but significantly less accurate.

Example 2.3. Taking \( k = 1 \) and \( f_1 = f = t \) we get \( \omega_f(r) = 1 \) for all prime \( r \), so that \( C = 1 \). Therefore, we obtain the two familiar versions of the Prime Number Theorem:

\[
\pi(x) \sim \text{Li}(x) := \int_{2}^{x} \frac{dt}{\ln t} \sim \frac{x}{\ln x}.
\]

The function \( \text{Li}(x) \) is also called the offset logarithmic integral function. The estimate \( x/\ln x \) is that of Hadamard and de la Vallée Poussin, while the estimate \( \text{Li}(x) \) is a particular case of the BHC. To
compare these two estimates, let us take \( \pi(10^{25}) = 176 \, 846 \, 309 \, 399 \, 143 \, 769 \, 411 \, 680 \) (see the entry A006880 of [36]). Then the relative error of the estimate \( 10^{25}/\ln(10^{25}) \) is \(-1.77\%\), while that of the estimate \( \text{Li}(10^{25}) \) is \(3.12 \cdot 10^{-11}\%\).

For a heuristic proof of the BHC see the original paper [3] by Bateman and Horn and also a recent overview [1].

**Remark 2.4** (An improved estimate). Li [33] has recently proposed a modification of the BHC, in which \( 1/\ln f_i(t) \) is used instead of \( 1/d_i \ln t \). This gives significantly better estimates \( E(x) \) in cases such as the Sophie Germain primes conjecture involving a non-monic polynomial \( f_i \), but when each \( f_i \) is monic, as in our case, the effect is negligible.

### 3. Irreducibility of the polynomial \((t^{ne} - 1)/(t^e - 1)\)

In order to apply the BHC to the projective groups of prime degree we consider two polynomials, \( f_1 = t \) and \( f_2 = (t^{ne} - 1)/(t^e - 1) \), and we need to ensure that the polynomial \( f_2 \) is irreducible.

**Lemma 3.1.** Given integers \( n \geq 2 \) and \( e \geq 1 \), the polynomial

\[
 f_2(t) = \frac{t^{ne} - 1}{t^e - 1} = 1 + t^e + t^{2e} + \cdots + t^{(n-1)e}
\]

is irreducible in \( \mathbb{Z}[t] \) if and only if \( n \) is prime and \( e \) is a power \( n^i \) \((i \geq 0)\) of \( n \).

**Proof.** If \( k \in \mathbb{N} \) the cyclotomic polynomial \( \Phi_k(x) \) is, by definition, the polynomial with integer coefficients whose roots are the primitive \( k \)th roots of unity. It is irreducible and has degree \( \varphi(k) \), where \( \varphi \) is the Euler totient function. For any \( n \in \mathbb{N} \) we have \( x^n - 1 = \prod_{d|n} \Phi_d(x) \) (see [5, §5.2.1] or [35, §4.3, Problem 26]). Putting \( x = t^e \) gives

\[
 f_2(t) = \frac{t^{ne} - 1}{t^e - 1} = \prod_d \Phi_d(t),
\]

with the product over all \( d \) which divide \( ne \) but not \( e \). Thus \( f_2 \) is irreducible if and only if there is just one such divisor \( d \) (which is \( ne \) itself, of course). By considering the prime power decompositions of \( e \) and \( ne \) one can see that this happens if and only if \( n \) is prime and \( e \) is a power of \( n \). \( \square \)

### 4. Primality testing

To find \( Q(x) \) for various large \( x \), we used the Rabin–Miller (RM) primality test [38]. It determines whether a given number is prime or composite without trying to factor it but by checking independent instances of a necessary primality condition. There is a real abyss between the complexities of the most efficient factoring algorithms and the RM-test. To give but one example, it took 4400 GHz-years to factor a 232-digit number into two 116-digit primes, see [39]. The RM-test gives a correct answer (“the number is composite”) in less than 0.0005 seconds on a very modest laptop.

The RM-test is probabilistic. If it affirms that a given number is composite, then it is indeed composite. If, however, the test affirms that a number is prime, the number may turn out to be composite. The probability of such an event is infinitesimally small: during 40 years of widespread use
of the RM-test not a single such error has ever been reported\textsuperscript{1}. Note also that long computations are prone to hardware errors. If, however, by incredibly bad luck a few of our ‘primes’ are composite, this would not invalidate our evidence of literally millions of projective primes.

5. Applying the Bateman–Horn Conjecture to projective groups

5.1. Relative abundance of types of projective primes. We tested the BHC estimates for projective primes against the results of computer searches. Define a projective prime $m = 1 + q + \cdots + q^{a-1}$ with $q = p^e$, $p$ prime, to have type $(e, n)$. For each type satisfying Lemma 3.1 define $P(x) = P_{(e,n)}(x)$ to be the number of primes $p \leq x$ such that $p$ and $m$ are prime, and let $E(x) = E_{(e,n)}(x)$ be the corresponding Bateman–Horn estimate (1) for $P_{(e,n)}(x)$, formed using the polynomials $f_1(t) = t$ and $f_2(t) = 1 + t^e + t^{2e} + \cdots + t^{(n-1)e}$.

The smallest projective primes $m$, as a function of $p$, are those of type $(1, 3)$, of the form $m = 1 + p + p^2$ with $p$ prime (recall that we have excluded the case $n = 2$), so this type appears most frequently in searches up to a given bound. For example, all but 301 of the 1974311 projective primes $m \leq 10^{18}$ have type $(1, 3)$. The second most frequent type is $(1, 5)$, with 252 examples $m \leq 10^{18}$.

| Segment       | #(prime $p$) | #(prime $m$) | ratio   | max p         |
|---------------|--------------|--------------|---------|---------------|
| $2, \ldots, 10^{10}$ | 455 052 511  | 15 801 827  | 3.473%  | 9 999 999 491 |
| $10^{10}, \ldots, 2 \cdot 10^{10}$ | 427 154 205  | 13 882 936  | 3.250%  | 9 999 999 757 |
| $2 \cdot 10^{10}, \ldots, 3 \cdot 10^{10}$ | 417 799 210  | 13 279 095  | 3.178%  | 9 999 999 921 |
| $3 \cdot 10^{10}, \ldots, 4 \cdot 10^{10}$ | 411 949 507  | 12 913 713  | 3.135%  | 9 999 999 719 |
| $4 \cdot 10^{10}, \ldots, 5 \cdot 10^{10}$ | 407 699 145  | 12 645 233  | 3.102%  | 9 999 999 619 |
| $5 \cdot 10^{10}, \ldots, 6 \cdot 10^{10}$ | 404 383 577  | 12 439 618  | 3.076%  | 9 999 999 429 |
| $6 \cdot 10^{10}, \ldots, 7 \cdot 10^{10}$ | 401 661 384  | 12 274 191  | 3.056%  | 9 999 999 287 |
| $7 \cdot 10^{10}, \ldots, 8 \cdot 10^{10}$ | 399 359 707  | 12 136 112  | 3.039%  | 9 999 999 679 |
| $8 \cdot 10^{10}, \ldots, 9 \cdot 10^{10}$ | 397 369 745  | 12 010 780  | 3.023%  | 9 999 999 981 |
| $9 \cdot 10^{10}, \ldots, 10^{11}$ | 395 625 822  | 11 910 803  | 3.011%  | 9 999 999 977 |
| Total         | 4 118 054 813 | 129 294 308 | 3.140%  | 9 999 999 977 |

Table 1. The second column gives the number of primes in the corresponding segment, while the third column gives the number of those primes $p$ which yield a projective prime $m = 1 + p + p^2$. The proportion of such primes among all the primes of the second column is given in the fourth column.

As further evidence for the abundance of projective primes of type $(1, 3)$, our colleague Jean Bétréma examined all primes $p \leq 10^{11}$ using the package Primes.jl of the language Julia. This

\textsuperscript{1} A dialogue from Gilbert and Sullivan’s *I am the Captain of the Pinafore* comes to mind: “What, never? No, never. What, never? Well, hardly ever”.

is much more efficient than Maple for problems of this sort. We partially reproduce Bétréma’s results in Table 1.

Thus 129 294 308 primes \( p \leq 10^{11} \) give a prime \( m \) of type (1, 3); the largest is 99 999 999 977, with \( m = 9 999 999 995 500 000 000 507 \). The ratio decreases as the upper limit grows, but it seems reasonable to conjecture that even in this restricted case there are infinitely many projective primes.

In making our estimates, we concentrated on the apparently most abundant case of type (1, 3), though we did not neglect other apparently less frequent types, such as (1, 5) and (3, 3). For types (1, \( n \)) with \( n \) prime the polynomials \( f_1 = t \) and \( f_2 = 1 + t + t^2 + \ldots + t^{n-1} \) satisfy the conditions of the BHC. The roots of \( f = f_1 f_2 \) in \( \mathbb{F}_r \) are 0 for all primes \( r \), together with 1 if \( r = n \), and the \( n-1 \) primitive \( n \)-th roots of 1 if \( r \equiv 1 \mod (n) \), so \( \omega_f(r) = 2, n \) or 1 as \( r = n, r \equiv 1 \mod (n) \) or otherwise.

### 5.2. Type (1, 3).

Using these values for \( n = 3 \), we computed \( C = C(f_1, f_2) = 1.521730 \) by taking partial products in (2) over the primes \( r \leq 10^9 \). To count primes \( m = 1 + p + p^2 \leq 10^{18} \) we took \( p \leq x = 10^9 \) (solving \( 1 + x + x^2 = 10^{18} \) would be more precise, but the difference is negligible).

Using numerical integration, Maple gives

\[
\int_2^x \frac{dt}{(\ln t)^2} = 2.594 294.364,
\]

leading to an estimate

\[
E(x) = E_{(1,3)}(x) = \frac{C}{2} \int_2^x \frac{dt}{(\ln t)^2} = 1.973 907.86.
\]

Comparing this with the true value \( P(x) = P_{(1,3)}(x) = 1.974 010 \), found by computer search, shows that the error in \( E(x) \) is about -0.0052%.

As a second experiment with type (1, 3) we took \( x = i \cdot 10^{10} \) for \( i = 1, 2, \ldots, 10 \). Table 2 gives the resulting values of \( P(x) \), \( E(x) \) and \( E(x)/P(x) \). The maximum relative error, attained in the first line, is 0.034%.

### 5.3. Type (1, 5).

For projective primes of type (1, 5), using \( f_1 = t \) and \( f_2 = 1 + t + \cdots + t^4 \) we found that \( C = 2.571048 \). To count such primes \( m \leq 10^{18} \) we took \( x = 10^{9/2} \). Maple gives

\[
\int_2^x \frac{dt}{(\ln t)^2} = 383.84,
\]

so that

\[
E_{(1,5)}(x) = \frac{C}{4} \int_2^x \frac{dt}{(\ln t)^2} = 246.72,
\]

compared with the true value \( P_{(1,5)}(x) = 252 \).

### 5.4. Type (3, 3).

With \( f_1 = t \) and \( f_2 = 1 + t^3 + t^6 \), we found that \( C = 2.086089 \). Taking \( x = 10^3 \), Maple gives

\[
E_{3,3}(x) = \frac{C}{6} \int_2^x \frac{dt}{(\ln t)^2} = 12.06,
\]

compared with the true value \( P_{(3,3)}(x) = 10 \).
Table 2. The second column gives the numbers \( P(x) = P_{1,3}(x) \) of projective primes \( m = 1 + p + p^2 \) for primes \( p \leq x = i \cdot 10^{10} \), where \( i = 1, \ldots, 10 \) (the cumulative totals from Table 1), the third column gives the corresponding Bateman–Horn estimates \( E(x) = E_{1,3}(x) \) for \( P(x) \), and the fourth column gives the ratios \( E(x)/P(x) \).

| \( x \)       | \( P(x) \)                         | \( E(x) \)                          | \( E(x)/P(x) \)         |
|-------------|----------------------------------|-----------------------------------|------------------------|
| 1 \cdot 10^{10} | 15 801 827                      | 1.579642126 \times 10^7           | 0.9996579044          |
| 2 \cdot 10^{10} | 29 684 763                      | 2.968054227 \times 10^7           | 0.9998578150          |
| 3 \cdot 10^{10} | 42 963 858                      | 4.296235691 \times 10^7           | 0.9999650617          |
| 4 \cdot 10^{10} | 55 877 571                      | 5.587447496 \times 10^7           | 0.9999445924          |
| 5 \cdot 10^{10} | 68 522 804                      | 6.852175590 \times 10^7           | 0.9999847043          |
| 6 \cdot 10^{10} | 80 962 422                      | 8.096382889 \times 10^7           | 1.0000173771          |
| 7 \cdot 10^{10} | 93 236 613                      | 9.323905289 \times 10^7           | 1.0000261688          |
| 8 \cdot 10^{10} | 105 372 725                     | 1.053741048 \times 10^8           | 1.0000130940          |
| 9 \cdot 10^{10} | 117 383 505                     | 1.173885689 \times 10^8           | 1.0000431394          |
| 10^{11}       | 129 294 308                     | 1.292974079 \times 10^8           | 1.0000239757          |

5.5. **Other types** \((e, n)\). For other fixed types \((e, n)\) there are too few projective primes within our range of feasible computation for comparisons to be meaningful. Nevertheless, in all cases \( E_{(e,n)}(x) \to \infty \) as \( x \to \infty \), so the accuracy of the above estimates encourages us to conjecture that there are infinitely many projective primes of each possible type \((e, n)\).

5.6. **Fixed** \( q, n \to \infty \). Computer searches for fixed \( q \) and \( n \to \infty \) are even more difficult, and the BHC no longer applies (though similar heuristic estimates are possible), so rather than making a conjecture we simply ask whether any fixed \( q \) (necessarily prime, by Lemma 3.1) yields infinitely many projective primes. This generalises the Mersenne primes problem for \( q = 2 \).

6. **Groups of prime power degree**

Although Section 5 of this paper concentrates on those cases where the natural degree \( m \) of \( PSL_n(q) \) is prime, there is also interest in cases such as \( PSL_2(8) \) and \( PSL_3(3) \) where \( m \) is a prime power \((3^2 \text{ and } 11^2 \text{ respectively})\). For instance, Guralnick [24] has shown that if a nonabelian simple group \( S \) has a transitive representation of prime power degree, then \( S \) is an alternating group or \( PSL_n(q) \) acting naturally, or \( PSL_2(11), M_{11} \text{ or } M_{23} \) acting as in (c) in Section 1, or the unitary group \( U_4(2) \cong Sp_4(3) \cong O_5(3) \) permuting the 27 lines on a cubic surface. In particular, \( S \) is doubly transitive in all cases except the last, where it has rank 3. See also [14], where Estes, Guralnick, Schacher and Straus have shown that for each prime \( p \) there are only finitely many \( e, q, n \geq 3 \) such that \( p^e = (q^n - 1)/(q - 1) \).

If \( n \) is composite then \( PSL_n(q) \) cannot have prime degree, but could it have prime power degree? More generally, while a reducible polynomial \( f(t) \in \mathbb{Z}[t] \) can take only finitely many prime values, can it take infinitely many prime power values? This issue is addressed in [30].
7. Linear groups of prime degree

One can also apply this technique to other situations within Group Theory, such as the classification of linear groups of prime degree, where ‘degree’ in this context means the degree, or dimension $m$, of a faithful irreducible matrix representation over $\mathbb{C}$. For example, in [12] Dixon and Zalesskii have classified the finite primitive subgroups $G \leq \text{SL}_{m}(\mathbb{C})$, for prime $m$, that is, those which preserve no non-trivial direct sum decomposition of the natural module $\mathbb{C}^{m}$. The centre $Z$ of $G$, consisting of scalar matrices, has order 1 or $m$; if the socle (subgroup generated by the minimal normal subgroups) $M$ of $G/Z$ is abelian then $G/Z$ is an extension of a normal subgroup $M \cong C_{m} \times C_{m}$ by an irreducible subgroup of $\text{SL}_{2}(m)$, all of which are known; the authors therefore concentrate on the case where $M$ is non-abelian, dealing in the main paper with the case where $M$ acts primitively, and in a corrigendum with the imprimitive case (see Subsection 7.6 for the latter).

If $M$ is primitive then it is a non-abelian simple group $S$ with $G/Z \leq \text{Aut} S$. Theorem 1.2 of [12] gives a finite list of families of simple groups $S$ which can arise, with necessary and sufficient conditions on $m$ and their parameters for such groups $G$ to exist. This result is analogous to our description in Section 1 of the permutation groups of prime degree, in the sense that for some families it is unknown whether these conditions are satisfied by finitely or infinitely many sets of parameters. For several of these families one can provide evidence for the latter by using the BHC in the same way as we have applied it to permutation groups $\text{PSL}_{m}(q)$ of prime degree. The relevant cases are as follows.

7.1. Unitary groups. As a simple example, Case (4) of Theorem 1.2 includes groups $G$ for which $S$ is isomorphic to the unitary group $\text{PSU}_{n}(q)$, where the degree

$$m = \frac{q^{n} + 1}{q + 1} = 1 - q + q^{2} - \cdots + q^{n-1}$$

of the representation is prime, so that $n$ is an odd prime. (Here, as usual, $q$ denotes a prime power.) It is unknown whether there are finitely or infinitely many such pairs $(n, q)$ for which $m$ is prime.

The BHC estimates $E(x)$ for the pair of irreducible polynomials

$$f_{1}(t) = t \quad \text{and} \quad f_{2}(t) = 1 - t^{e} + t^{2e} - \cdots + t^{(n-1)e}$$

are identical to those for $f_{1}(t) = t$ and $f_{2}(t) = 1 + t^{e} + t^{2e} + \cdots + t^{(n-1)e}$ which we found in Section 5: the values of $\omega_{j}(r)$ are the same for all primes $r$, since there is a bijection $t \mapsto -t$ between the roots of the two polynomials $f = f_{1}f_{2} \mod (r)$ for each $r$, while all other ingredients of (1) and (2) are unchanged. It follows that our earlier estimates $E_{(e,n)}(x)$ for permutation groups $\text{PSL}_{n}(q)$ of degree $(q^{n} - 1)/(q - 1)$ all apply in this new situation. The only difference is in the verification of these estimates, where we determine the actual number $Q(x) = Q_{(e,n)}(x)$ of primes $t \leq x$ such that $1 - t^{e} + t^{2e} - \cdots + t^{(n-1)e}$ is prime.

Some results of this kind are shown in Table 3, where the first column shows the type $(e, n)$, and the second and third columns show the numbers of primes $m \leq 10^{18}$ of the forms $(q^{n} - 1)/(q - 1)$ and $(q^{n} + 1)/(q + 1)$, where $q = p^{e}$. (The prime $m = 31$ is counted twice in the second column, once each for types $(1, 3)$ and $(1, 5)$.) The exceptional cases are defined to be those not of type $(1, 3)$.
Since the BHC estimates $E_{(e,n)}(x)$ for these two families of primes are identical, and are almost identical with Li's amendment, and since they agree very closely and fairly closely with the computer searches in the two main cases of types $(1, 3)$ and $(1, 5)$, we extend our conjecture of infinitely many primes $(q^n - 1)/(q - 1)$ for any given prime $n \geq 3$ to those of the form $(q^n + 1)/(q + 1)$, and hence to the associated linear groups $G$ of these degrees.

| $(e, n)$ | $(q^n - 1)/(q - 1)$ | $(q^n + 1)/(q + 1)$ |
|---------|---------------------|---------------------|
| (1, 3)  | 1974 010            | 1973 762            |

Table 3. The second and third columns show the numbers of primes $m \leq 10^{18}$ of the forms $(q^n - 1)/(q - 1)$ and $(q^n + 1)/(q + 1)$, where $q = p^e$. The type $(e, n)$ is indicated in the first column.

7.2. **Projective special linear groups.** Several other cases in [12, Theorem 1.2] can be treated in a similar way by using the BHC. For example, Case (2)(ii) includes groups $G$ with $S \cong \text{PSL}_2(q)$ where $q$ and the degree $m = (q - 1)/2$ are both prime, that is, $m$ is a Sophie Germain prime, one
for which $2m + 1$ is also prime. In this case we can take
\begin{equation}
  f_1(t) = t \ (= m) \quad \text{and} \quad f_2(t) = 2t + 1 \ (= q),
\end{equation}
giving
\begin{equation}
  C = C(f_1, f_2) = 2 \prod_{\text{prime } r > 2} \left( 1 - \frac{1}{r} \right)^2 \left( 1 - \frac{2}{r} \right)
\end{equation}
(the same as for twin primes, where $f_i(t) = t$ and $t + 2$, since in both cases $\omega_f(r) = 1$ or 2 as $r = 2$ or $r > 2$, see [1]). This time, the constant is known with great accuracy: it is equal to $2C_2$ where the constant $C_2 = 0.66016181584686957393$ (see [36], entry A001692) is called the Hardy–Littlewood twin primes constant. With a non-monic polynomial $f_2$, it is now more accurate to use Li’s improvement of the BHC
\begin{equation}
  E(x) = C \int_2^x \frac{dt}{\ln(t) \cdot \ln(2t + 1)}
\end{equation}
(see Remark 2.4), as he has shown in [33], where his Table 2 compares his estimates for $x = 10^n$ ($n = 2, \ldots, 10$) with those using the original BHC formula and with the actual number $Q(x)$. We reproduce here his results, removing those of the original BHC, computing the integrals a little more accurately, and adding the relative errors of the estimates, see Table 4.

| $x$  | $Q(x)$ | $E(x)$ | relative error |
|------|--------|--------|----------------|
| $10^2$ | 10 | 10.20 | 2.00 % |
| $10^3$ | 37 | 39.10 | 5.67 % |
| $10^4$ | 190 | 194.58 | 2.41 % |
| $10^5$ | 1 171 | 1 165.95 | −0.43 % |
| $10^6$ | 7 746 | 7 810.64 | 0.83 % |
| $10^7$ | 56 032 | 56 127.94 | 0.17 % |
| $10^8$ | 423 140 | 423 294.39 | 0.036 % |
| $10^9$ | 3 308 859 | 3 307 887.89 | −0.029 % |
| $10^{10}$ | 26 569 515 | 26 568 824.04 | −0.0026 % |

Table 4. $Q(x)$ is the number of $t \leq x$ such that both $t$ and $2t + 1$ are prime; $E(x)$ is the estimate of $Q(x)$ given by formula (7).

To compare two estimates, we may take the original BHC estimate for $x = 10^{10}$, namely,
\begin{equation}
  C \int_2^{10^{10}} \frac{dt}{(\ln t)^2} = 27 411 416.53
\end{equation}
with the relative error 3.17 %. This accuracy is also not bad, but $−0.0026 \%$ is significantly better.

The above estimates provide strong support for the conjecture that there are infinitely many Sophie Germain primes, and hence that there are infinitely many linear groups $G$ in the family under consideration.
Case (2)(iii) of [12, Theorem 1.2] concerns groups $G$ for which $S \cong \text{PSL}_2(q)$ where the degree $m = (q + 1)/2$ is prime and $q = p^k \geq 5$ for some odd prime $p$ and integer $k \geq 0$. Here we can choose some fixed $k \geq 0$, and take

\begin{equation}
(8) \quad f_1(t) = 2t + 1 \ (= p) \quad \text{and} \quad f_2(t) = \frac{(2t + 1)^2 + 1}{2} = \sum_{i=1}^{2^k} \binom{2^k}{i} 2^{i-1}t^i + 1 \ (= m).
\end{equation}

For example, if $k = 0$ then $f_2(t) = t + 1$, so writing $s := t + 1$ we can apply the BHC (+Li) to the polynomials $g_1(s) = s \ (= m)$ and $g_2(s) = 2s - 1 \ (= p)$; then $C(g_1, g_2) = 1.3203236316 \ldots$ again.

**Lemma 7.1.** Let $f_1$ and $f_2$ be as in (8), and denote $d = 2^k$, $k \geq 1$. Then

\begin{equation}
(9) \quad \omega_f(r) = \begin{cases} 
0 & r = 2, \\
d + 1 & \text{if } r \equiv 1 \text{ mod } (2d), \\
1 & \text{otherwise}.
\end{cases}
\end{equation}

**Proof.** The equation $f_1 = 2t + 1 = 0$ has a single root for any $r \neq 2$. What remains is to show that the equation $f_2(t) = 0$ has $d$ roots if $r \equiv 1 \text{ mod } (2d)$, and no roots otherwise.

For each prime $r$, the multiplicative group $U_r$ of units mod $(r)$ is cyclic, of order $r-1$. Hence, for any $n$, the number of solutions of $x^n = 1$ in $U_r$ is $\gcd(n, r-1)$, and the number of elements of order exactly $n$ is $\phi(n)$ if $n$ divides $r-1$ and $0$ otherwise. For $r > 2$ the solutions of $x^{2k} = -1 \text{ mod } (r)$ are the elements of order exactly $2 \cdot 2^k = 2^{k+1}$, so the number of them is $\phi(2^{k+1}) = 2^k$ or $0$ as $2^{k+1}$ divides $r-1$ or not, that is, as $r \equiv 1 \text{ mod } (2^{k+1})$ or not. □

Lemma 7.1 allows us to compute the constants $C(f_1, f_2)$, which we will denote here by $C(k)$ according to the exponent $k$ in $f_2$, so that $\deg f_2 = d = 2^k$. All the constants in Tables 5 and 6 are computed over $r$ up to $10^9$.

| $d = 2^k$ | $C(k)$ | $Q(10^9)$ | $E(10^9)$ | relative error |
|---|---|---|---|---|
| 2 | 4.426783 | 5448994 | 5448648.05 | -0.006% |
| 4 | 10.433814 | 6373197 | 6365668.39 | -0.118% |
| 8 | 7.885346 | 2394012 | 2395075.38 | 0.044% |
| 16 | 14.642571 | 2219445 | 2218975.66 | -0.021% |

**Table 5.** $Q(10^9)$ is the number of $t \leq 10^9$ such that both $f_1(t)$ and $f_2(t)$ are prime; $E(10^9)$ is the BHC-estimate of $Q(10^9)$.

It is too time-consuming to compute further the values of $Q(x)$ since the numbers $f_2(t)$ become too large, but the computation of the constants $C(k)$ does not present any additional difficulties. Therefore, we give, in Table 6, a few additional values of this constant.
7.3. Irregular behaviour of the constants \( C(k) \). It is interesting that in this example, as \( k \) increases, the Hardy–Littlewood constant \( C = C(k) \) also increases, but does not do so monotonically. The following is a heuristic explanation of this curious phenomenon.

For each \( k \geq 1 \) we have \( \omega f(2) = 0 \), so (2) gives

\[
C(k) = 4 \prod_{r>2} c_r
\]

where

\[
c_r = \left( 1 - \frac{1}{r} \right) \left( 1 - \frac{\omega f(r)}{r} \right)
\]

for each prime \( r > 2 \). Hence

\[
\ln C(k) = \ln 4 + \sum_{r>2} \ln c_r,
\]

where

\[
\ln c_r = -2 \ln \left( 1 - \frac{1}{r} \right) + \ln \left( 1 - \frac{\omega f(r)}{r} \right) \approx \frac{2 - \omega f(r)}{r}
\]

for each prime \( r > 2 \). Now \( \omega f(r) \) is the number of roots of the polynomial \( x(x^{2^k} + 1) \mod (r) \), that is, \( 1 + 2^k \) or \( 1 \) as \( r \equiv 1 \mod (2^{k+1}) \) or not, so that

\[
\ln c_r \approx \frac{1 - 2^k}{r} \quad \text{or} \quad \frac{1}{r}
\]

respectively.

Let us define \( r_k \) to be the least prime \( r \equiv 1 \mod (2^{k+1}) \), and let us partition the set of primes \( r > 2 \) into three sets: the set \( U_k \) of those \( r < r_k \), the set \( V_k \) of those \( r \equiv 1 \mod (2^{k+1}) \), and the set \( W_k \) of those satisfying \( r_k \leq r \neq 1 \mod (2^{k+1}) \). Now odd primes \( r \) are evenly distributed between the \( 2^k \) congruence classes of units \( \mod (2^{k+1}) \), so as \( r \) increases, those in \( W_k \) appear \( 2^k - 1 \) times as frequently as those in \( V_k \). It follows that the positive and negative contributions to (10) of primes in these two sets approximately cancel, leaving just the contributions from primes in \( U_k \). Thus

\[
\ln C(k) \approx \ln 4 + \sum_{r \in U_k} \ln c_r \approx \ln 4 + \sum_{2<r<r_k} \frac{1}{r} \approx \ln 4 + \ln(\ln r_k) - \frac{1}{2} + b,
\]

(see [25, Theorem 427] or [35, Theorem 8.8(d)]) where

\[
b := \lim_{x \to \infty} \left( \sum_{r \leq x} \frac{1}{r} - \ln(\ln x) \right) = 0.2614972128 \ldots
\]

is the Meissel–Mertens constant, and hence

\[
C(k) \approx 4e^{b-1/2} \ln r_k = 4e^{b-1/2} \ln(2^{k+1}q_k + 1) \approx 4e^{b-1/2}((k+1) \ln 2 + \ln q_k)
\]
where \(q_k := (r_k - 1)/2^{k+1}\) for each \(k \geq 1\).

Now the sequence of primes
\[
r_k = 5, 17, 17, 97, 257, 257, 7681, 12289, 12289, 40961, 65537, 65537, 786433, \ldots
\]
gives the sequence of integers \(q_k\) shown, for \(k = 1, \ldots, 16\) in Table 7, with the values of \(C(k)\), rounded to the nearest integer, shown for comparison. The irregular behaviour of the terms \(\ln q_k\) disturbs the steady increase of the terms \((k + 1)\ln 2\) in (11). In particular, if \(q_k\) is even then \(q_{k+1} = q_k/2\) and hence \(\ln q_{k+1} = \ln q_k - \ln 2\), explaining the occasional ‘plateaux’ in the sequence of constants \(C(k)\).

| \(k\) | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| \(C(k)\) \(\approx\) | 4 | 10 | 8 | 15 | 14 | 16 | 30 | 30 | 32 | 29 | 34 | 34 | 32 | 23 | 45 |
| \(q_k\) | 1 | 2 | 1 | 3 | 3 | 2 | 1 | 15 | 12 | 6 | 3 | 5 | 4 | 2 | 1 | 6 |

Table 7. \(C(k)\) (to the nearest integer) and \(q_k\) for \(k = 1, \ldots, 16\).

Both sequences \(r_k\) and \(b_k\) may be found in the entries A035089 and A035050 of [36], respectively; to get our sequences, the first two terms of these entries should be removed.

The above argument clearly lacks rigour: for example, we have not quantified the errors introduced by the linear approximation of logarithms, or the extent to which the contributions from primes in \(V_k\) and \(W_k\) ‘approximately cancel’. Moreover, instead of defining \(U_k\) by the inequality \(r < r_k\) we could have reduced this upper bound, and argued as before, resulting in a smaller multiplicative constant in (11). However, our aim here is explanation rather than precise proof, revealing a cause for the irregular behaviour of the constants \(C(k)\) as \(k\) increases, rather than trying to estimate them accurately. We leave that to the experts in this area of number theory.

7.4. Symplectic groups. Case (3)(i) of [12, Theorem 1.2] concerns groups \(G\) for which \(S \cong \text{PSp}_{2n}(q)\) where the degree \(m = (q^n + 1)/2\) is prime, \(n (> 1)\) is a power of 2, and \(q = p^{2^k}\) for some odd prime \(p\) and integer \(k \geq 0\). Here we can choose some fixed pair \(j, k \geq 0\), put \(n = 2^j\), and take

\[
(12) \quad f_1(t) = 2t + 1 \quad (\equiv p) \quad \text{and} \quad f_2(t) = \frac{(2t + 1)^{2^j + k} + 1}{2} \quad (\equiv m).
\]

These are the same as the pair \(f_1, f_2\) in (8), but with \(j + k\) replacing \(k\), so the same estimates \(E(x)\) and search results \(Q(x)\) apply in this case.

7.5. The remaining families. The other families of groups in [12, Theorem 1.2] are either

(a) obviously infinite, namely

(a1) Case 1, with \(S \cong A_{m+1}\) for primes \(m \geq 7\), or
(a2) Case 2(i), with \(S \cong \text{PSL}_2(m)\) for primes \(m \geq 11\), or

(b) obviously finite, namely Case 5, with

(b1) \(m = 3\) and \(S \cong \text{PSL}_2(9) \cong A_6\),
(b2) \(m = 7\) with \(S \cong \text{PSp}_6(2)\),
(b3) \(m = 11\) with \(S \cong M_{12}\), or
(b4) $m = 23$ with $S \cong \text{Co}_2$, $\text{Co}_3$ or $M_{23}$, or

(c) beyond the scope of the BHC, involving exponential functions rather than polynomials, namely

(c1) Case 2(iv), with primes $m = 2^n - 1$ and $S \cong \text{PSL}_2(2^n)$,

(c1) Case 2(ii), with primes $m = (3^n - 1)/2$ and $S \cong \text{PSL}_2(3^n)$, or

(c2) Case 3(ii), with primes $m = (3^n - 1)/2$ and $S \cong \text{PSp}_{2n}(3)$, where $n$ is an odd prime in all three cases.

The primes $m$ appearing in (c1) are the Mersenne primes, while those appearing in (c2) and (c3) appear to be equally difficult to deal with. There is heuristic evidence to support conjectures that both sets are infinite, but proofs seem to be very far away.

7.6. **Imprimitive groups.** An irreducible linear group $G$ of prime degree $m$ is imprimitive if and only if it acts transitively on the $m$ 1-dimensional subspaces in a direct sum decomposition of its natural module. This action gives an epimorphism from $G$ to a transitive permutation group $H$ of degree $m$; its kernel $D$, conjugate to a group of diagonal matrices, is abelian. We have listed the possibilities for $H$ in Section 1. Now $G$ is solvable if and only if $H$ is, in which case the latter acts as a subgroup of $\text{AGL}_1(m)$. This case having been dealt with by other authors, Dixon and Zalesskii considered the nonsolvable imprimitive linear groups of degree $m$ in [13], this time over an arbitrary algebraically closed field; of course, our results concerning the groups $H = \text{PSL}_n(q)$ have some relevance here. The technical problems to be overcome in classifying the groups $G$ are considerable: given $H$, one has to consider which diagonal groups $D$ it can act on, whether or not the corresponding extensions split, and whether or not the resulting groups $G$ are conjugate in the general linear group. The results obtained in [13] are too complicated to state here.

In the corrigendum of [12] it is shown that if $G$ is primitive and the socle $M$ of $G/Z$ is imprimitive and non-abelian, then the commutator subgroup $G'$ is imprimitive and isomorphic to $\text{PSL}_n(q)$ where $m = (q^n - 1)/(q - 1)$, with $q$ odd or $G' \cong \text{PSL}_3(2)$ if $n \geq 3$. Conversely, such groups $G$ exist provided $m \geq 5$. Again, our results on $\text{PSL}_n(q)$ are relevant in this case.

8. RELATED PROBLEMS

8.1. **Waring’s Problem.** Projective primes have occasionally been examined by number theorists, but in a completely different context, that of Waring’s Problem (see [25, Ch. XX], for example). This asks whether, for each integer $m \geq 1$, there is an integer $g(m)$ such that each positive integer is a sum of at most $g(m)$ $m$-th powers. For instance $g(1) = 1$, and $g(2) = 4$ by Lagrange’s Four Squares Theorem. After Hilbert [27] proved the existence of $g(m)$ in 1909, Tornheim [42] and Bateman and Stemmler [4] considered similar problems in other number systems. In each case, they took $m$ to be prime for simplicity, and encountered extra difficulties when $m$ was what we have called a projective prime. The reason is that if $m = (q^n - 1)/(q - 1)$ then every $m$-th power in the field $\mathbb{F}_{q^n}$ lies in the subfield $\mathbb{F}_q$, so elements outside $\mathbb{F}_q$ cannot be sums of $m$-th powers.

This problem was also important in another way: an investigation in [4] of the frequency of the occurrence of the above phenomenon led Bateman and Horn [3] to their conjecture.
8.2. Error-correcting codes. The results on projective primes in Section 5 are also relevant to
the classification of non-elementary cyclic linear codes of prime length by Guenda and Gulliver
in [23], where class (v) in their Theorem 3 consists of codes with associated permutation group
PTL,(q) acting with prime degree (q, - 1)/(q - 1).

8.3. Block designs. A construction by Amarra, Devillers and Praeger [2] of block-transitive point-
imprimitive 2-designs with specific parameters depends on certain polynomials, such as f(t) =
32t^2 + 20t + 1, taking prime power values. Using all primes r < 10^8 gives C(f) = 4.721240, and Li’s
modified BHC then gives an estimate E(10^8) = 12 362 961.06. In fact, there are 12 357 532 values
of t ≤ 10^8 such that f(t) is prime. The relative error is 0.044%. See [30] for other polynomials and
further details.

8.4. Difference sets. A construction of divisible difference sets by Fernández-Alcober, Kwashira
and Martínez in [19, Proposition 4.1] depends on the existence of prime powers q such that 3q - 2
is also a prime power. In such generality, this situation is beyond the scope of the BHC, but one
can deal with the case where q and 3q - 2 are both prime by applying it to the polynomials f_1 = t
and f_2 = 3t - 2. We find that C = 2.640647, leading to an estimate E(10^9) = 6 485 752.27 for the
number of such primes q ≤ 10^9, compared with the actual number Q(10^9) = 6 484 218 found by
computer search. The relative error is 0.024%.

More generally, one can deal with the case where q is a prime power and 3q - 2 is prime by
taking f_1 = t and f_2 = 3t^e - 2 for some fixed e. For example, if we take e = 2 then C = 2.540480,
giving an estimate E(10^9) = 3 205 208.84 for the number of such primes t = \sqrt[3]{q} ≤ 10^9, compared
with the actual number Q(10^9) = 3 203 900. In this case the relative error is 0.041%.

One can also deal with the case where q is a prime power and 3q - 2 is a proper prime power p^e by using
the polynomials t (= p) and (t^e + 2)/3 (= q) for fixed e ≥ 2; we need t^e ≡ 1 mod (3) in order
to have integer coefficients, so write t = 3s + 1, giving polynomials 3s + 1 and ((3s + 1)^e + 2)/3 in Z[s], or t = 3s - 1 with e even, giving polynomials 3s - 1 and ((3s - 1)^e + 2)/3 in Z[s]. For
instance if e = 2 we can apply the BHC to two pairs of polynomials, namely 3s + 1, 3s^2 + 2s + 1,
and 3s - 1, 3s^2 - 2s + 1; in the first case we get an estimate of 4 892 910.99 and an actual number
4 893 804 (error -0.018%), with corresponding values 4 892 911.60 and 4 894 315 (error -0.029%)
in the second case.

These results strongly suggest that there are infinitely many pairs of prime powers q and 3q - 2
with at least one of them prime. This might suggest a similar conjecture in the remaining case,
where both q and 3q - 2 are proper prime powers, but here we have Mihailescu’s proof of the
Catalan Conjecture as a warning. Similarly, there is Pillai’s conjecture that for fixed integers
A, B, C > 0 there are only finitely many integer solutions of the equation Ax^m - By^n = C with
m, n > 2. Thus the status of this part of the construction seems to be an interesting open problem.

We close with two conjectures which, while much less important than those considered in Sec-
tion 2, nevertheless have their own interest.

8.5. The Goormaghtigh Conjecture (1917). Since

1 + 2 + 2^2 + 2^3 + 2^4 = 31 = 1 + 5 + 5^2,
both PSL$_3(2)$ and PSL$_3(5)$ have natural degree 31. Goormaghtigh, a Belgian engineer and amateur mathematician, conjectured in [21] that this example and

$$1 + 2 + 2^2 + \cdots + 2^{12} = 8191 = 1 + 90 + 90^2$$

are the only positive integer solutions of $(x^n - 1)/(x - 1) = (y^k - 1)/(y - 1)$ with $n \neq k$ and $n, k \geq 3$. This conjecture is still open. Although 8191 is prime, 90 is not a prime power, so only the first example is relevant to permutation groups PSL$_n(q)$.

8.6. **The Feit–Thompson Conjecture (1962).** Feit and Thompson [17] conjectured that if $p$ and $q$ are distinct primes then $(p^q - 1)/(p - 1)$ does not divide $(q^p - 1)/(q - 1)$. They stated that if true this would significantly shorten their 255-page proof [18] that groups of odd order are solvable. However, an alternative simplification was found by Peterfalvi [37] in 1984. The conjecture has been proved by Le [31] for $q = 3$, but it is otherwise still open.

9. **Acknowledgements**

We are greatly indebted to Yuri Bilu who acquainted us with the Bunyakovsky conjecture, which became a crucial point of our study, and to Peter Cameron, Robert Guralnick, Weixiong Li, Valery Liskovets, Cheryl Praeger and Dimitri Zvonkine for some very useful comments. Jean Bétréma helped us with some computations which were too onerous for our Maple package on a laptop computer. Alexander Zvonkin is partially supported by the ANR project **Combiné** (ANR-19-CE48-0011).

2Numerous publications give the following wrong title for Bunyakovsky’s paper: “Nouveaux théorèmes relatifs à la distinction des nombres premiers et à la décomposition des entiers en facteurs”. According to the French Wikipedia (see [7], visited on 11 June, 2021), an article with this title does indeed exist, but it was published in 1840 and not in 1857, and it does not discuss the conjecture in question. The reader may also consult the original paper reproduced in the Google archive (the link is given in [6]).
