CONVERGENCE AND ERROR ESTIMATES FOR TIME-DISCRETE
CONSENSUS-BASED OPTIMIZATION ALGORITHMS

SEUNG-YEAL HA, SHI JIN, AND DOHEON KIM

Abstract. We present convergence and error estimates of the time-discrete consensus-based optimization (CBO) algorithms proposed in [4] for general nonconvex functions. In authors’ recent work [14], rigorous error analysis of the first-order consensus-based optimization algorithm proposed in [4] was studied at the particle level without resorting to the kinetic equation via a mean-field limit. However, the error analysis for the corresponding time-discrete algorithm was not done mainly due to lack of discrete analogue of Itô’s stochastic calculus. In this paper, we provide a simple and elementary convergence and error analysis for a general time-discrete consensus-based optimization algorithm, which includes the three discrete algorithms in [4]. Our analysis provides numerical stability and convergence conditions for the three algorithms, as well as error estimates to the global minimum.

1. Introduction

The purpose of this work is to complete the convergence and error analysis for discrete consensus-based optimization algorithms introduced in [4, 14]. For modern machine learning methods, one needs to solve non-convex optimization problems in high dimensions. It is well-known that non-convex optimization problem is NP-hard. Usually a deterministic algorithm, such as the gradient descent method, will get stuck to local minima. In order to escape from local minima, or saddle points, one needs to introduce some numerical noises which allow the algorithms to escape from the local minima or saddle points. For this reason, stochastic optimizations—such as the stochastic gradient descent method, have been widely used in machine learning [3]. On the other hand, gradient-free algorithms, which do not need the gradient of objective functions, are attractive for problems with non-smooth objective functions or data-based optimization problems. Meta-heuristic stochastic optimization algorithms belong to the latter category, for example swarm intelligence methods [19, 52] such as particle swarm optimization (in short PSO) [10], simulated annealing method [20, 24], ant-colony algorithm [31], genetic algorithm [17] etc. A basic idea of these meta-heuristic algorithms is to use collective behaviors of underlying individual agents (or particles) coupled with suitable stochastic components in the choice of system parameters. Although each individual moves in some random fashion, one designs suitable communication functions between the particles such that colectively they exhibit some intelligent behavior, such as moving toward the global minimum. Although these algorithms are usually simple to implement and yields reasonably

The authors would like to thank to Dr. Dongnam Ko for his helpful comments on the Laplace principle.
good results with suitable choices of parameters, their rigorous convergence analysis were mostly open as far as the authors know.

Our main interest in this paper lies on the first-order consensus based optimization algorithm, first introduced in \cite{27} and studied in \cite{5}, and then modified in \cite{4} (see also \cite{29} for comparisons between CBO algorithm and other heuristic algorithms based on collective dynamics). These are swarming intelligence models that can be proved to exhibit consensus approximating the global minimum of general nonconvex functions under suitable conditions on the parameters and initial data. We also refer to recent works on the consensus-based optimization algorithm on the sphere \cite{12,13}.

We begin with the continuous optimization algorithm. Let $X^k_t = (x^k_1, \cdots, x^k_d) \in \mathbb{R}^d$ be the coordinate of the $k$-th particle at time $t$, and $L = L(X)$, $X \in \mathbb{R}^d$ be a non-convex objective function to be minimized. Then, the main goal of optimization algorithms is to look for a global minimizer $X^*$ of $L$ in the search space (in our setting, the whole space) if it exists:

$$X^* \in \text{argmin}_{X \in \mathbb{R}^d} L(X).$$

In a recent work \cite{4}, the authors proposed the following variant of the CBO algorithm introduced in \cite{5,27}:

$$
\begin{align*}
\{ & dX^i_t = -\lambda(X^i_t - \bar{X}^*)dt + \sigma \sum_{l=1}^{d}(x^{i,l}_t - \bar{x}^{*,l}_t)dW^l_t, \quad t > 0, \quad i = 1, \cdots, N, \\
& \bar{X}^*_t = (x^{*,1}_t, \cdots, x^{*,d}_t) := \frac{\sum_{j=1}^{N} X^j_t e^{-\beta L(X^j_t)}}{\sum_{j=1}^{N} e^{-\beta L(X^j_t)}},
\end{align*}
$$

(1.1)

where $\lambda$ and $\sigma$ denote the drift rate and noise intensity, respectively, and $\beta > 0$ is a positive constant corresponding to the reciprocal of temperature in statistical physics. Here $\{e_l\}$ is the standard orthonormal basis in $\mathbb{R}^d$. The one-dimensional Brownian motions $W^l_t$ are assumed to be i.i.d. and satisfy the zero mean and covariance relations:

$$
\mathbb{E}[W^l_t] = 0 \quad \text{for} \quad l = 1, \cdots, d \quad \text{and} \quad \mathbb{E}[W^l_t W^{l'}_t] = \delta_{ll'}t, \quad 1 \leq l_1, l_2 \leq d.
$$

This model is an example of agent-based swarming models which have been studied intensively in recent years, see for example several survey articles \cite{1,2,6,28,30} and related literature \cite{8,11,15,16,21,22,23,25,26}.

Next, we consider time-discrete analogue of (1.1). For this, we set

$$h := \Delta t, \quad X_n := X(nh), \quad n = 0, 1, \cdots, \cdots.$$

Then the discrete scheme reads as follows:

$$
\begin{align*}
\{ & X^i_{n+1} = X^i_n - \gamma(X^i_n - \bar{X}^*_n) - \sum_{l=1}^{d}(x^{i,l}_n - \bar{x}^{*,l}_n)\eta^l_n, \quad n \geq 0, \quad i = 1, \cdots, N, \\
& \bar{X}^*_n = (x^{*,1}_n, \cdots, x^{*,d}_n) := \frac{\sum_{j=1}^{N} X^j_n e^{-\beta L(X^j_n)}}{\sum_{j=1}^{N} e^{-\beta L(X^j_n)}},
\end{align*}
$$

(1.2)

where the random variables $\{\eta^l_n\}_{n,l}$ are i.i.d. with

$$
\mathbb{E}[\eta_n] = 0, \quad \mathbb{E}[|\eta^l_n|^2] = \zeta^2, \quad n = 1, \cdots, \quad l = 1, \cdots, d.
$$

(1.3)
Note that the discrete process \( \{ \eta_{n,l} \}_{n,l} \) certainly includes the Gaussian noise process. In this sense, the discrete model (1.2) clearly generalizes the discrete model studied in [14].

In this paper, we are interested in the following issues for the discrete algorithm (1.2):

- (Question A): Does the \( N \)-state ensemble \( \{ X_n^i \} \) exhibit a global consensus? i.e., does
  \[
  X_n^i - X_n^j \to 0 \quad \text{as} \quad n \to \infty, \quad i, j = 1, \cdots, N \quad \text{in suitable sense?}
  \]

- (Question B): If the answer to the first problem is positive, then under what conditions on system parameters and initial data, does there exist a global consensus state \( X_\infty \) such that
  \[
  X_n^i \to X_\infty \quad \text{for all } i, \quad \text{as } n \to \infty, \quad \text{such that } L(X_\infty) \sim \min_X L(X).
  \]

In [14], the above two questions were answered positively for the continuous algorithm (1.1), whereas for the discrete algorithm (1.2), only the first question was discussed in the same paper. For a rigorous error analysis to the continuous algorithm, Itô’s calculus was essentially used. The main reason that we did not cover the second question for the discrete algorithm is mainly due to the lack of the discrete analogue of Itô’s stochastic calculus.

In this paper, we revisit the second question on the convergence of the discrete algorithm (1.2) and provide positive answer for the generalized discrete algorithm (1.2) which can cover several discrete algorithms proposed in [4] (see Section 2.1 for details). Our analysis also provides numerical stability conditions and error estimates for these algorithms.

Next, we summarize our main results as follows. First, we provide several stochastic global consensus results in suitable sense. More precisely, if system parameters \( \gamma \) and \( \zeta \) in (1.2) and (1.3) satisfy
\[
|1 - \gamma| < 1, \quad 0 \leq \zeta \leq \infty,
\]
then the expectation of \( X_n^i - X_n^j \) tends to zero asymptotically:
\[
\lim_{n \to \infty} \mathbb{E}[X_n^i - X_n^j] = 0, \quad \forall \ i, j = 1, \cdots, N.
\]
On the other hand, if system parameters satisfy a more restricted condition compared to (1.4):
\[
(1 - \gamma)^2 + \zeta^2 < 1,
\]
then \( L^2 \)-global consensus and almost-sure global consensus occur asymptotically:
\[
\lim_{n \to \infty} \mathbb{E}|X_n^i - X_n^j|^2 = 0 \quad \text{and} \quad \mathbb{P} \left\{ \lim_{n \to \infty} |X_n^i - X_n^j| = 0 \right\} = 1, \quad \forall \ i, j = 1, \cdots, N,
\]
where \(| \cdot |\) stands for the \( L^2 \)-norm of a vector.

Moreover, the above \( L^2 \)-global consensus also implies the \( L^1 \)-global consensus. We refer to Definition 2.1 and Theorem 2.1 for the definition of convergences and details.

Note that the above global consensus does not imply the existence of asymptotic consensus state \( X_\infty \) independent of \( i \) such that
\[
X_n^i \to X_\infty \quad \text{in suitable sense},
\]
i.e., the process can fluctuate, but the relative distances tends to zero asymptotically, for example, the sample paths may tend to periodic orbit or limit cycle. Our second result provides the condition under which the process tends to a common fixed random variable \( X_\infty \) (see (1.6)).
fact, under the same assumption (1.5), one can show that there exists a common constant state
\(X_\infty = (x_1^\infty, \ldots, x_d^\infty)\) such that
\[
\lim_{n \to \infty} X^i_n = X^\infty \quad \text{a.s., } 1 \leq i \leq N.
\]
(see Theorem 3.1 for details).

Finally, our last result establishes the condition under which the asymptotic state
\(X^\infty\) lies in a small neighborhood of a unique global minimum \(X^*_m\) for a large \(\beta\). More precisely, under the assumption (1.5) and for a well-prepared initial random variable \(X^*_m\) such that \(X^i_n \sim X^*_m\), we derive a key estimate (see Proposition 3.1):
\[
\text{essinf}_{\omega \in \Omega} L(X^\infty) \leq -\frac{1}{\beta} \log \mathbb{E} e^{-\beta L(X^*_m)} - \frac{1}{\beta} \log \varepsilon.
\]
Then, by Laplace’s method (18), one can derive
\[
\text{essinf}_{\omega \in \Omega} L(X^\infty) \leq L(X^*_m) + \frac{d}{2} \log \beta + E(\beta),
\]
for some function \(E(\beta) = O\left(\frac{1}{\beta}\right), \beta \gg 1\). We refer to Remark A.1 for the intriguing relation between \(\beta\) and admissible reference random variable \(X^*_m\).

The rest of this paper is organized as follows. In Section 2, we provide reductions of previously studied discrete algorithms to (1.2) - (1.3), and then study our first set of main results on the global consensus. In Section 3, we study the emergence of a global consensus state and provide error estimates toward the global minimum for (1.2). Finally, Section 4 is devoted to a brief summary of our main results and some remaining issues to be explored in a future work.

**Notation.** For a random variable \(Z \in \mathbb{R}\) on the probability space \((\Omega, \mathcal{F}, \mathbb{P})\), we denote its mean by \(\mathbb{E}Z\) or \(\mathbb{E}[Z]\) interchangeably.

### 2. Emergence of Global Consensus

In this section, we first show that several discrete algorithms introduced in [4, 14] can be reduced to our generalized discrete algorithm (1.2) and then we provide a sufficient framework leading to the global consensus for the discrete optimization algorithm in terms of system parameters and initial data.

#### 2.1. Discrete algorithms.** In this subsection, we show how the previous discrete algorithms studied can be reduced as special cases for our general discrete model.

Let \(X^k_n = (x^k_{1n}, \ldots, x^k_{dn}) \in \mathbb{R}^d\) be the position of the \(k\)-th particle at time \(n\) \((1 \leq k \leq N)\). Suppose that the function \(L: \mathbb{R}^d \to \mathbb{R}\) has exactly one global minimum, and we consider the general discrete consensus-based optimization algorithm:

\[
\begin{align*}
X^i_{n+1} &= X^i_n - \gamma(X^i_n - \bar{X}^*_n) - \sum_{l=1}^{d}(x^i_{ln} - \bar{x}^*_{ln})\eta^l ne_l, \quad n \geq 0, \quad i = 1, \ldots, N, \\
\bar{X}^*_n &= (x^*_{1n}, \ldots, x^*_{dn}) := \frac{\sum_{j=1}^{N} X^i_j e^{-\beta L(X^i_j)}}{\sum_{j=1}^{N} e^{-\beta L(X^i_j)}}.
\end{align*}
\]
where \( \{e_t\} \) is the standard orthonormal basis in \( \mathbb{R}^d \) and random variables \( \{\eta^l_n\}_{n,l} \) are i.i.d with
\[
\mathbb{E}[\eta^l_n] = 0 \quad \text{and} \quad \mathbb{E}[\eta^l_n]^2 = \zeta^2.
\]
In the sequel, we consider the following three discrete algorithms.

- **Model A**: Consider the first-order Euler type discrete model in [14]:
\[
X^i_{n+1} = X^i_n - \lambda h (X^i_n - \bar{X}^i_n) - \sum_{l=1}^d (\bar{x}^{i,l}_n - \bar{x}^{*,l}_n) \sigma \sqrt{h} Z^l_n e_t, \quad n \geq 0, \ i = 1, \ldots, N,
\]
where the random variables \( \{Z^l_n\}_{n,l} \) are i.i.d standard normal distributions, i.e. \( Z^l_n \sim \mathcal{N}(0, 1^2) \). If we set
\[
\gamma := \lambda h \quad \text{and} \quad \eta^l_n := \sigma \sqrt{h} Z^l_n.
\]
Then, the above setting clearly satisfies the relations (2.2) with \( \zeta = \sigma \sqrt{h} \).

- **Model B**: Consider a predictor-corrector type discrete model in [4]:
\[
\begin{cases}
\hat{X}^i_n = \hat{X}^i_n + e^{-\lambda h} (X^i_n - \bar{X}^i_n), \\
X^i_{n+1} = \hat{X}^i_n - \sum_{l=1}^d (\hat{x}^{i,l}_n - \hat{x}^{*,l}_n) \sigma \sqrt{h} Z^l_n e_t, \quad n \geq 0, \ i = 1, \ldots, N.
\end{cases}
\]
We substitute (2.4) into (2.4) and use an addition-subtraction trick to see that
\[
X^i_{n+1} = X^i_n - (1 - e^{-\lambda h}) (X^i_n - \bar{X}^i_n) - \sum_{l=1}^d (\hat{x}^{i,l}_n - \hat{x}^{*,l}_n) e^{-\lambda h} \sigma \sqrt{h} Z^l_n e_t, \quad n \geq 0, \ i = 1, \ldots, N.
\]
If we set
\[
\gamma := 1 - e^{-\lambda h} \quad \text{and} \quad \eta^l_n := e^{-\lambda h} \sigma \sqrt{h} Z^l_n,
\]
then (2.4) reduces to the special case of (2.1) - (2.2) with \( \zeta = e^{-\lambda h} \sigma \sqrt{h} \).

- **Model C**: Consider one of discrete optimization model proposed in [4]:
\[
X^i_{n+1} = \bar{X}^i_n + \sum_{l=1}^d (x^{i,l}_n - \bar{x}^{*,l}_n) \left[ \exp \left( - \left( \lambda + \frac{1}{2} \sigma^2 \right) h + \sigma \sqrt{h} Z^l_n \right) \right] e_t, \quad n \geq 0, \ i = 1, \ldots, N,
\]
Again, the R.H.S. of (2.6) can be rewritten as
\[
X^i_{n+1} = X^i_n - (1 - e^{-\lambda h}) (X^i_n - \bar{X}^i_n) - \sum_{l=1}^d (x^{i,l}_n - \bar{x}^{*,l}_n) \sigma \sqrt{h} Z^l_n e_t - \left[ \exp \left( - \frac{1}{2} \sigma^2 h + \sigma \sqrt{h} Z^l_n \right) - 1 \right] e_t.
\]
We set
\[
\gamma := 1 - e^{-\lambda h} \quad \text{and} \quad \eta^l_n := e^{-\lambda h} \left[ \exp \left( - \frac{1}{2} \sigma^2 h + \sigma \sqrt{h} Z^l_n \right) - 1 \right],
\]
Then, we use the elementary facts [7]:
\[
X \sim \text{Lognormal(}\alpha, \beta^2\) \quad \Rightarrow \quad \mathbb{E}X = e^{\alpha + \frac{\beta^2}{2}} \quad \text{and} \quad \mathbb{E}X^2 = e^{2\alpha + 2\beta^2}
\]
to see that (2.7) satisfies moment relations (2.2) with \( \zeta = e^{-\lambda h} \sqrt{e^{2\alpha h} - 1} \).
2.2. Global consensus. In this subsection, we show that the global consensus for (2.1) occurs asymptotically for all initial data under suitable conditions on \( \gamma \) and \( \zeta \). First, we recall the concepts of \( L^p \) and almost sure global consensus in the following definition.

**Definition 2.1.** Let \( \mathcal{X} = \{ X_n := (x_1^n, \cdots , x_d^n) \} \) be a stochastic process, and let \( (\Omega, \mathcal{F}, \mathbb{P}) \) be the underlying probability space.

1. The configuration process \( X \) exhibits a global consensus in \( L^p \) with \( p \geq 1 \), if the following zero \( L^p \)-convergence holds:
   \[
   \lim_{n \to +\infty} \mathbb{E}|X_i^n - X_j^n|^p = 0, \quad \forall \ i, j = 1, \cdots , N.
   \]

2. The configuration process \( X \) exhibits a global consensus almost surely if for almost sure \( \omega \in \Omega \) and \( i, j = 1, \cdots , N \), the sample path \( X_i^n(\omega) - X_j^n(\omega) \) tends to zero asymptotically.

\[
\mathbb{P}\left\{ \lim_{n \to \infty} |X_i^n - X_j^n| = 0 \right\} = 1, \quad \forall \ i, j = 1, \cdots , N.
\]

**Remark 2.1.** Recall that \( L^2 \)-convergence implies \( L^1 \) convergence on a probability space.

Now, we consider the relation for the process \( X_i^n - X_j^n \). For this, we consider the discrete algorithms: for \( i, j = 1, \cdots , N \),

\[
\begin{align*}
X_i^{n+1} &= X_i^n - \gamma (X_i^n - \bar{X}_n^i) - \sum_{l=0}^{d} (x_{i,l}^n - \bar{x}_{i,l}^n) \eta_{i,l}^n e_l, \\
X_j^{n+1} &= X_j^n - \gamma (X_j^n - \bar{X}_n^j) - \sum_{l=0}^{d} (x_{j,l}^n - \bar{x}_{j,l}^n) \eta_{j,l}^n e_l,
\end{align*}
\]

Then, it follows from (2.8) that \( x_{i,n+1}^i - x_{n+1}^j \) satisfies

\[
(2.9) \quad x_{i,n+1}^i - x_{n+1}^j = (1 - \gamma - \eta_i^n)(x_i^n - x_j^n).
\]

In the following lemma, we provide several estimates for \( x_{i,n}^i - x_{n}^j \).

**Lemma 2.1.** Let \( \{ X_n \} \) be a solution process to (2.1). Then the following estimates hold.

1. \( \mathbb{E}|X_i^n - X_j^n| = (1 - \gamma)^n \mathbb{E}|X_0^i - X_0^j| \).
2. \( \mathbb{E}|X_i^n - X_j^n|^2 = ((1 - \gamma)^2 + \zeta^2)^n \mathbb{E}|X_0^i - X_0^j|^2 \).
3. \( |x_{i,n}^i - x_{n}^j|^2 \leq |x_{0}^i - x_{0}^j|^2 e^{-nY_n^l(\omega)} \), \ a.s. \ \omega \in \Omega,

where \( Y_n^l \) is a random variable satisfying

\[
\lim_{n \to \infty} Y_n^l(\omega) = 2\gamma - \gamma^2 - \zeta^2, \quad \text{a.s.} \ \omega \in \Omega, \quad l = 1, \cdots , d.
\]

**Proof.** The estimates below for a special case (Model A) can be found in Theorem 3.4 in [14] and proofs are almost similar. However, for self-containedness of this paper, we present their proofs.

(i) It follows from the recursive relation (2.9) that

\[
(2.10) \quad x_{i,n}^i - x_{n}^j = (x_{0}^i - x_{0}^j) \prod_{m=0}^{n-1} (1 - \gamma - \eta_m^l), \quad l = 1, \cdots , d.
\]

Now we take expectation on both sides of (2.10) using the independence of \( \eta_m^l \) and \( x_{0}^{i,l} - x_{0}^{j,l} \) to get

\[
\mathbb{E}[x_{i,n}^i - x_{n}^j] = (1 - \gamma)^n \mathbb{E}[x_{0}^{i,l} - x_{0}^{j,l}], \quad \text{i.e.,} \quad \mathbb{E}[X_i^n - X_j^n] = (1 - \gamma)^n \mathbb{E}[X_0^i - X_0^j].
\]
(ii) We take the square of (2.10) to see

\begin{equation}
|x_n^{i,l} - x_n^{j,l}|^2 = |x_0^{i,l} - x_0^{j,l}|^2 \prod_{m=0}^{n-1} |1 - \gamma - \eta_m|^2, \quad l = 1, \ldots, d.
\end{equation}

Then, (1.3), (2.11), independence of \( \eta_m \) and \( x_0^{i,l} - x_0^{j,l} \) yield

\[ \mathbb{E}|x_n^{i,l} - x_n^{j,l}|^2 = ((1 - \gamma)^2 + \zeta^2)^n \mathbb{E}|x_0^{i,l} - x_0^{j,l}|^2, \]

i.e.,

\[ \mathbb{E}|X_n^i - X_n^j|^2 = ((1 - \gamma)^2 + \zeta^2)^n \mathbb{E}|X_0^i - X_0^j|^2. \]

(iii) It follows from the inequality \( e^x \geq 1 + x, \quad x \in \mathbb{R} \) that

\begin{equation}
(1 - \gamma - \eta_m)^2 \leq e^{(1-\gamma-\eta_m)^2-1} = e^{-(\gamma+\eta_m)(2-\gamma-\eta_m)}.
\end{equation}

Then, we use (2.11) and (2.12) to obtain

\[ |x_n^{i,l} - x_n^{j,l}|^2 \leq |x_0^{i,l} - x_0^{j,l}|^2 \prod_{m=0}^{n-1} e^{-(\gamma+\eta_m)(2-\gamma-\eta_m)} \]

\[ = |x_0^{i,l} - x_0^{j,l}|^2 \exp \left[ -n \times \frac{1}{n} \sum_{m=0}^{n-1} (\gamma + \eta_m)(2 - \gamma - \eta_m) \right]. \]

We set

\[ Y_n := \frac{1}{n} \sum_{m=0}^{n-1} (\gamma + \eta_m)(2 - \gamma - \eta_m). \]

Then, we use the strong law of large numbers to see

\[ Y_n \longrightarrow \mathbb{E} \left[ (\gamma + \eta_m)(2 - \gamma - \eta_m) \right] = 2\gamma - \gamma^2 - \zeta^2 \quad \text{a.s. as } n \to \infty. \]

As a direct application of Lemma 2.1, we have the following global consensus estimates.

**Theorem 2.1.** Let \( \{X_n\} \) be a solution process to (2.1). Then, the following three global consensus results hold.

1. Suppose that system parameters satisfy

\[ |\gamma - 1| < 1 \quad \text{and} \quad 0 \leq \zeta \leq \infty. \]

Then, \( \mathbb{E}[X_n^i - X_n^j] \) tends to zero asymptotically:

\[ \lim_{n \to \infty} \mathbb{E}[X_n^i - X_n^j] = 0, \quad \forall \ i, j = 1, \ldots, N. \]

2. Suppose that system parameters \( \gamma \) and \( \zeta \) satisfy

\[ (\gamma - 1)^2 + \zeta^2 < 1 \]

then, \( L^2 \) and almost-sure global consensus emerge asymptotically: for a.s. \( \omega \in \Omega \),

\[ \lim_{n \to \infty} \mathbb{E}|X_n^i - X_n^j|^2 = 0, \quad \mathbb{E}|x_n^{i,l} - x_n^{j,l}|^2 \leq |x_0^{i,l} - x_0^{j,l}|^2 e^{-nY_n^l(\omega)}, \quad i, j = 1, \ldots, N, \quad l = 1, \ldots, d, \]

where \( Y_n^l \) is a random variable satisfying

\[ \lim_{n \to \infty} Y_n^l(\omega) = 1 - (\gamma - 1)^2 - \zeta^2 > 0, \quad \text{a.s. } \omega \in \Omega, \quad l = 1, \ldots, d. \]
Proof. Since the proofs follow from Lemma 2.1 directly, we omit them here.

As a corollary of Theorem 2.1, one has the following global consensus for Model A - Model C discussed in previous subsection.

**Corollary 2.1.** The following assertions hold.

1. Suppose that system parameters satisfy
   \[ \lambda > \frac{\sigma^2}{2}, \quad 0 < h < \frac{2\lambda - \sigma^2}{\lambda^2}, \]
   then, Model A admits \( L^2 \) and almost sure global consensus.

2. Suppose that system parameters satisfy
   \[ (1 + \sigma^2 h) e^{-2\lambda h} < 1, \]
   then, Model B admits \( L^2 \) and almost sure global consensus.

3. Suppose that system parameters satisfy
   \( (2.13) \)
   \[ \lambda > \frac{\sigma^2}{2}, \]
   then, Model C admits \( L^2 \) and almost sure global consensus, for any \( h > 0 \).

**Proof.**

(i) For Model A, we use relations \( \gamma = \lambda h, \ \zeta = \sigma \sqrt{h} \) in (2.3) to see
   \[ 2\gamma - \gamma^2 - \zeta^2 = 2\lambda h - (\lambda h)^2 - \sigma^2 h > 0, \quad \text{for} \quad 0 < h < \frac{2\lambda - \sigma^2}{\lambda^2}. \]
   Then, we use (3) in Theorem 2.1 to derive the desired estimate.

(ii) For Model B, we use relations \( \gamma = 1 - e^{-\lambda h}, \ \zeta = e^{-\lambda h} \sigma \sqrt{h} \) in (2.5) to see
   \[ 2\gamma - \gamma^2 - \zeta^2 = 2(1 - e^{-\lambda h}) - (1 - e^{-\lambda h})^2 - \sigma^2 h e^{-2\lambda h} = 1 - (1 + \sigma^2 h) e^{-2\lambda h} > 0. \]

(iii) For Model C, we use \( \gamma = 1 - e^{-\lambda h}, \ \zeta = e^{-\lambda h} \sqrt{e^{\sigma^2 h} - 1} \) in (2.7) to get
   \[ 2\gamma - \gamma^2 - \zeta^2 = 2(1 - e^{-\lambda h}) - (1 - e^{-\lambda h})^2 - (e^{\sigma^2 h} - 1) e^{-2\lambda h} = 1 - e^{(\sigma^2 - 2\lambda)h} > 0 \iff (2\lambda - \sigma^2) h > 0. \]

**Remark 2.2.** The above corollary provides the stability conditions for three algorithms. For Model C, the algorithm is unconditionally stable provided (2.13) holds, namely one can choose arbitrary \( h > 0 \). Model B is also unconditionally stable provided \( \lambda \geq \frac{\sigma^2}{2} \) is satisfied, because
   \[ e^{2\lambda h} > 1 + 2\lambda h \geq 1 + \sigma^2 h, \quad \text{for} \quad h > 0. \]

Model A is conditionally stable.

3. **Convergence analysis and error estimates**

In this section, we provide a convergence analysis with error estimates for the discrete CBO algorithm. In previous section, we studied sufficient conditions leading to the global consensus which does not mean \( X^i_n \) tends to a common fixed state \( X_\infty \). Thus, two main issues to be covered in this section are two-fold.

- (Q1): What is a sufficient framework leading to the common asymptotic state:
  \[ X^i_n(\beta) \to X_\infty(\beta), \quad \text{as} \quad n \to \infty \quad \text{for all} \quad i = 1, \cdots, N? \]
• (Q2): If the above question is resolved, then how close is the asymptotic state \( X_\infty \) to the global minimum \( X_m \) of \( L \) if the latter exists?

3.1. Emergence of common consensus state. For the emergence of common consensus state, we first introduce an ensemble average:

\[
\bar{X}_n := \frac{1}{N} \sum_{i=1}^{N} X^i_n = (\bar{x}^1_n, \cdots, \bar{x}^d_n).
\]

Before we present our second main result, we present two elementary lemmas to be crucially used in the proof of convergence analysis.

**Lemma 3.1.** Let \( \{X^i_n\}_{1 \leq i \leq N} \) be a solution to (2.1). Then, the following estimates hold almost surely.

\[
(i) |X^i_n - \bar{X}_n|^2 = \sum_{l=1}^{d} (x^i_{0,l} - \bar{x}_0^l)^2 \prod_{m=0}^{n-1} \left( 1 - \gamma - \eta_m^l \right)^2.
\]

\[
(ii) |\bar{X}_n - \bar{X}_n|^2 \leq \max_{1 \leq i \leq N} |X^i_n - \bar{X}_n|^2.
\]

\[
(iii) \frac{1}{N} \sum_{i=1}^{d} |X^i_n - \bar{X}_n|^2 \leq 2 \sum_{l=1}^{d} \left( \max_{1 \leq i \leq N} (x^i_{0,l} - \bar{x}_0^l)^2 \right) \prod_{m=0}^{n-1} \left( 1 - \gamma - \eta_m^l \right)^2.
\]

**Proof.** (i) It follows from (2.1) that

\[
\bar{X}_{n+1} - \bar{X}_n = -\gamma (\bar{X}_n - \bar{X}_n) - \sum_{l=1}^{d} (\bar{x}_n^l - \bar{x}_n^l)\eta_n^l e_l.
\]

We subtract (3.1) from (2.1) to obtain

\[
(X^i_{n+1} - \bar{X}_{n+1}) - (X^i_n - \bar{X}_n) = -\gamma (X^i_n - \bar{X}_n) - \sum_{l=1}^{d} (x^i_{n,l} - \bar{x}_n^l)\eta_n^l e_l.
\]

The \( l \)-th component of (3.2) implies

\[
x^i_{n,l} - \bar{x}_n^l = (x^i_{0,l} - \bar{x}_0^l) \prod_{m=0}^{n-1} \left( 1 - \gamma - \eta_m^l \right).
\]

This yields

\[
|X^i_n - \bar{X}_n|^2 = \sum_{l=1}^{d} (x^i_{0,l} - \bar{x}_0^l)^2 \prod_{m=0}^{n-1} \left( 1 - \gamma - \eta_m^l \right)^2.
\]

(ii) We apply the triangle inequality and the Cauchy-Schwarz inequality:

\[
|\bar{X}_n - \bar{X}_n|^2 \leq \left[ \sum_{k=1}^{N} e^{-\beta \langle X^k_n \rangle} (\bar{X}_n - X^k_n) \right]^2 \leq \left[ \sum_{k=1}^{N} e^{-\beta \langle X^k_n \rangle} |\bar{X}_n - X^k_n| \right]^2 \leq \max_{1 \leq k \leq N} |\bar{X}_n - X^k_n|^2.
\]
Next, we show the a.s. convergence of $I_i$.

**Proof.** Note that summing the equation (2.1) over $l$ and $(i,l) = 1, \ldots, N$ and let
\[
\{X^n_i\}_{i,l} \rightarrow R_i
\]
be a solution to
\[
\tag{2.1}
\]
Then, there exists a common constant state $X_\infty = (x^1_\infty, \cdots, x^d_\infty)$ such that
\[
\lim_{n \to \infty} X^n_i = X_\infty \text{ a.s., } 1 \leq i \leq N.
\]

**Theorem 3.1.** Suppose that system parameters satisfy
\[
(1 - \gamma)^2 + \zeta^2 < 1,
\]
and let $\{X^n_i\}_{1 \leq i \leq N}$ be a solution to (2.1). Then, there exists a common constant state $X_\infty = (x^i_\infty, \cdots, x^d_\infty)$ such that
\[
\lim_{n \to \infty} X^n_i = X_\infty \text{ a.s., } 1 \leq i \leq N.
\]

**Proof.** Note that summing the equation (2.1) over $n$ yields the following relation: for $i = 1, \cdots, N$ and $l = 1, \cdots, d,$
\[
x_n^{i,l} = x_0^{i,l} - \gamma \sum_{m=0}^{n-1} (x_m^{i,l} - \bar{x}_m^{i,l}) - \sum_{m=0}^{n-1} (x_m^{i,l} - \bar{x}_m^{i,l}) \eta_m =: x_0^{i,l} - I_{31} - I_{32}.
\]
Next, we show the a.s. convergence of $I_{31}$ and $I_{32}$ separately.

(iii) Note that
\[
\frac{1}{N} \sum_{i=1}^{d} |X^n_i - X^*_n|^2 = \frac{1}{N} \sum_{i=1}^{d} \left( |X^n_i - X^*_n|^2 + 2(X^n_i - \bar{X}_{n}^i) \cdot (\bar{X}_{n}^i - X^*_n) + |X^n_i - X^*_n|^2 \right)
\]
\[
= \frac{1}{N} \sum_{i=1}^{d} \left( |X^n_i - X^*_n|^2 + |X^n_i - X^*_n|^2 \right) \leq 2 \max_{1 \leq i \leq N} |X^n_i - X^*_n|^2
\]
\[
= 2 \max_{1 \leq i \leq N} \left( \sum_{l=1}^{d} (x_0^{i,l} - \bar{x}_0^{i,l})^2 \prod_{m=0}^{n-1} \left( 1 - \gamma - \eta_m^l \right)^2 \right)
\]
\[
\leq 2 \sum_{l=1}^{d} \left( \max_{1 \leq i \leq N} (x_0^{i,l} - \bar{x}_0^l)^2 \right) \prod_{m=0}^{n-1} \left( 1 - \gamma - \eta_m^l \right)^2,
\]
where we used the results from (i) and (ii).

**Lemma 3.2.** Let $\{X^n_i\}_{1 \leq i \leq N}$ be a solution to (2.1). Then, one has
\[
E|X^n_i - X^*_n|^2 \leq 2((1 - \gamma)^2 + \zeta^2)^n \sum_{l=1}^{d} \left( E \max_{1 \leq i \leq N} (x_0^{i,l} - \bar{x}_0^l)^2 \right).
\]

**Proof.** We take expectation on both sides of the inequality in Lemma 3.1 (iii) to get
\[
E|X^n_i - X^*_n|^2 \leq 2 \sum_{l=1}^{d} \left( E \max_{1 \leq i \leq N} (x_0^{i,l} - \bar{x}_0^l)^2 \right) \prod_{m=0}^{n-1} E \left( 1 - \gamma - \eta_m^l \right)^2
\]
\[
\leq 2((1 - \gamma)^2 + \zeta^2)^n \sum_{l=1}^{d} \left( E \max_{1 \leq i \leq N} (x_0^{i,l} - \bar{x}_0^l)^2 \right).
\]
• (Estimate of $I_{31}$): By Lemma 3.1 (iii), we have

$$|x_m^i - x_m^*| \leq \sum_{i=1}^d |X_m^i - \bar{X}_m^*|$$

$$\leq 2N \sum_{l=1}^d \left( \max_{1 \leq i \leq N} (x_0^i - \bar{x}_0^l)^2 \right) \frac{m-1}{p=0}(1 - \gamma - \eta^l_p)^2$$

$$\leq 2N \sum_{l=1}^d \left( \max_{1 \leq i \leq N} (x_0^i - \bar{x}_0^l)^2 \right) \prod_{p=0}^{m-1} \exp ((1 - \gamma - \eta^l_p)^2 - 1)$$

$$= 2N \sum_{l=1}^d \left( \max_{1 \leq i \leq N} (x_0^i - \bar{x}_0^l)^2 \right) \exp \left( \sum_{p=0}^{m-1} (-2\gamma + \gamma^2 - 2(1 - \gamma)\eta_p + (\eta^l_p)^2) \right).$$

On the other hand, by the strong law of large numbers, one has

$$\lim_{m \to \infty} \frac{1}{m} \sum_{p=0}^{m-1} \left(-2\gamma + \gamma^2 - 2(1 - \gamma)\eta_p + (\eta^l_p)^2 \right)$$

$$= \mathbb{E} \left[-2\gamma + \gamma^2 - 2(1 - \gamma)\eta_p + (\eta^l_p)^2 \right] = -(2\gamma - \gamma^2 - \zeta^2), \quad \text{a.s.}$$

This yields that there exist positive random functions $C_i = C_i(\omega), \ i = 1, 2$ such that

$$|x_m^i - x_m^*| \leq C_1 e^{-C_2m}, \quad \text{a.s.} \ \omega \in \Omega,$$

where $C_1$ and $C_2$ are positive constants. We set

$$J_{31} := I_{31} - \gamma \sum_{m=0}^{n-1} C_1 e^{-C_2m} = \gamma \sum_{m=0}^{n-1} \left( x_m^i - \bar{x}_m^l - C_1 e^{-C_2m} \right).$$

Since the summand is nonpositive a.s., $J_{31}$ is non-increasing in $n$ a.s.

On the other hand, note that

$$J_{31} = I_{31} + \gamma \sum_{m=0}^{n-1} C_1 e^{-C_2m} - 2\gamma \sum_{m=0}^{n-1} C_1 e^{-C_2m}$$

$$= \gamma \sum_{m=0}^{n-1} \left( x_m^i - \bar{x}_m^l + C_1 e^{-C_2m} \right) - 2\gamma C_1 \frac{1 - e^{-C_2n}}{1 - e^{-C_2}} \geq -2\gamma C_1 \frac{1 - e^{-C_2n}}{1 - e^{-C_2}}.$$

Since $J_{31}$ is monotone decreasing and bounded below along sample paths, one has

$$\exists \alpha = \lim_{n \to \infty} J_{31}(n) = \lim_{n \to \infty} \left( I_{31} - \gamma \sum_{m=0}^{n-1} C_1 e^{-C_2m} \right), \quad \text{a.s.}$$

This implies

$$\lim_{n \to \infty} I_{31} = \alpha + \frac{C_1 \gamma}{1 - e^{-C_2}}, \quad \text{a.s.}$$
(Estimate of $I_{32}$): Note that $I_{32}$ is martingale and its $L^2(\Omega)$-norm is uniformly bounded in $n$:

\[
\mathbb{E}\left[\sum_{m=0}^{n-1} (x_{j,m}^i - \bar{x}_m^i) \eta_m^i\right]^2 = \zeta^2 \sum_{m=0}^{n-1} \mathbb{E}(x_{j,m}^i - \bar{x}_m^i)^2
\]

\[
\leq 2N\zeta^2 \left( \sum_{m=0}^{n-1} ((1-\gamma)^2 + \zeta^2)^m \right) \sum_{i=1}^d \left( \mathbb{E} \max_{1 \leq i \leq N} (x_{0,i}^i - \bar{x}_0^i)^2 \right)
\]

\[
\leq \frac{2N\zeta^2}{2\gamma - \gamma^2 - \zeta^2} \sum_{i=1}^d \left( \mathbb{E} \max_{1 \leq i \leq N} (x_{0,i}^i - \bar{x}_0^i)^2 \right).
\]

In the first inequality we used (iii). Hence $\lim_{n \to \infty} I_{32}$ exists a.s. Now we have shown that for each $i = 1, \ldots, N$, there exists some random variable $X_n^i$ such that

\[
\lim_{n \to \infty} X_n^i = X_\infty^i \quad \text{a.s.}
\]

Recall that by Theorem 2.1 for any $1 \leq i, j \leq N$,

\[
\lim_{n \to \infty} |X_n^i - X_n^j| = 0, \quad \text{a.s.}
\]

Hence, there exists $X_\infty$ such that

\[
X_\infty^i = X_\infty^j =: X_\infty \quad \text{a.s.}
\]

\[\square\]

3.2. Error estimate. In this subsection, we study an error analysis of (2.1) toward the global minimum. Below, we present a sufficient framework (A1) – (A3) for error analysis in terms of the objective function $L$, global minimum point $X_*$ and reference random variable $X_{in}$ as follows:

- (A1): Let $L = L(x)$ be a $C^2$-objective function satisfying the following relations:

  \[
  L_m := \min_{x \in \mathbb{R}^d} L(x) > 0 \quad \text{and} \quad C_L := \sup_{x \in \mathbb{R}^d} \|\nabla^2 L(x)\|_2 < \infty,
  \]

  where $\| \cdot \|_2$ denotes the spectral norm.

- (A2): Let $X_*$ be the unique global minimum point of $L$ in $\mathbb{R}^d$ satisfying the local convexity relation:

  \[
  \det (\nabla^2 L(X_*)) > 0.
  \]

- (A3): Let $X_{in}$ be a reference random variable with a law which is absolutely continuous with respect to the Lebesgue measure, and let $f$ be the probability density function of $X_{in}$ satisfying the following conditions:

  \[
  f \text{ is compactly supported, continuous at } X_*, \text{ and } f(X_*) > 0.
  \]

In the next theorem, we study how close is the common consensus state $X_\infty$ to the global minimum $X_*$ in suitable sense. Now, we are ready to provide an error analysis of the discrete CBO algorithm, which is analogous to Theorem 4.1 in [14] for the continuous case.
Theorem 3.2. Suppose that the framework (A1) – (A3) holds, and system parameters $\beta, \gamma, \zeta$ and the initial data $\{X^i_0\}$ satisfy

$$\beta > 0, \quad (\gamma - 1)^2 + \zeta^2 < 1, \quad X^i_0 : i, i.d, \quad X^i_0 \sim X^m,$$

(3.3)

$$\frac{2CL\sqrt{(1 + (1 - \gamma)^2 + \zeta^2)(\gamma^2 + \zeta^2)}\beta e^{-\beta L_m}}{1 - e^{-[1 - (\gamma - 1)^2 - \zeta^2]}} \sum_{l=1}^{d} \left( \mathbb{E} \max_{1 \leq i \leq N}(x^i_l - \bar{x}^l_0)^2 \right),$$

for some $0 < \varepsilon < 1$. Then for a solution $\{X^n_i\}_{1 \leq i \leq N}$ to (1.1), one has the following error estimate:

(3.4)

$$\left| \inf_{\omega \in \Omega} L(X^\infty) - L(X^s) \right| \leq \frac{d \log \beta}{2 \beta} + E(\beta),$$

for some function $E(\beta) = O\left(\frac{1}{\beta}\right)$.

Remark 3.1. 1. Note that the third condition (3.3) does hold only for some intermediate $\beta$ for given initial data satisfying

$$\sum_{l=1}^{d} \left( \mathbb{E} \max_{1 \leq i \leq N}(x^i_l - \bar{x}^l_0)^2 \right) > 0.$$ 

This can be checked as follows. We multiply $e^{\beta L_m}$ on the both sides of (3.5) to get

$$(1 - \varepsilon)\mathbb{E} [e^{-\beta L_m}] \geq \frac{2CL\sqrt{(1 + (1 - \gamma)^2 + \zeta^2)(\gamma^2 + \zeta^2)}\beta e^{-\beta L_m}}{1 - e^{-[1 - (\gamma - 1)^2 - \zeta^2]}} \sum_{l=1}^{d} \left( \mathbb{E} \max_{1 \leq i \leq N}(x^i_l - \bar{x}^l_0)^2 \right),$$

By letting $\beta \to \infty$ in the above relation, we can see that L.H.S. is less than or equal to $1 - \varepsilon$, but R.H.S. goes to $+\infty$. Hence, the estimate (3.4) is only an error estimate for the discrete CBO algorithm for fixed $\beta$ (indeed numerically one chooses a fixed $\beta$ for computation), not viewed as a convergence for $\beta \to \infty$ (which would impose restrictive constraints on the initial data from (3.3)).

In Appendix A, we provide an alternative error analysis for (1.1) without employing Laplace’s principle.

2. In the sequel, we check how the conditions in (3.3) can be reinterpreted for Model A - Model C in Section 2.1.
Model A: We use \((\lambda, \zeta) = (\lambda h, \sigma \sqrt{h})\) to rewrite (3.3) as
\[
\beta > 0, \quad \lambda > \frac{\sigma^2}{2}, \quad 0 < h < \frac{2\lambda - \sigma^2}{\lambda^2},
\]
\[
(1 - \varepsilon)\mathbb{E}\left[ e^{-\beta L(X_{in})} \right] \geq \frac{2C_L}{1 - e^{-\lambda(2h - \lambda^2 - \sigma^2)}} \times \sum_{l=1}^{d} \left( \mathbb{E} \max_{1 \leq i \leq N} (x_0^i - \bar{x}_0^l)^2 \right).
\]

Model B: We use \((\lambda, \zeta) = (1 - e^{-\lambda h}, e^{-\lambda h} \sigma \sqrt{h})\) to rewrite (3.3) as
\[
\beta > 0, \quad h > 0, \quad (1 + \sigma^2 h) e^{-2\lambda h} < 1,
\]
\[
(1 - \varepsilon)\mathbb{E}\left[ e^{-\beta L(X_{in})} \right] \geq \frac{2C_L}{1 - e^{-1/(1+\sigma^2 h) e^{-2\lambda h}} \times \sum_{l=1}^{d} \left( \mathbb{E} \max_{1 \leq i \leq N} (x_0^i - \bar{x}_0^l)^2 \right)}
\]

Model C: We use \((\lambda, \zeta) = (1 - e^{-\lambda h}, e^{-\lambda h} \sqrt{\sigma^2 h} - 1)\) to rewrite (3.3) as
\[
\beta > 0, \quad h > 0, \quad \lambda > \frac{\sigma^2}{2},
\]
\[
(1 - \varepsilon)\mathbb{E}\left[ e^{-\beta L(X_{in})} \right] \geq \frac{2C_L}{1 - e^{-1/(e^{\sigma^2 h} - 2\lambda h}) (1 + e^{-\lambda h (e^{-\lambda h} + e^{\sigma^2 h} - 3)})} \times \sum_{l=1}^{d} \left( \mathbb{E} \max_{1 \leq i \leq N} (x_0^i - \bar{x}_0^l)^2 \right).
\]

Before we present a proof of Theorem 3.2, we first briefly review Laplace’s principle with a convergence rate.

- **(Laplace’s principle with a rate for \(\beta \gg 1\):** Note that under some suitable conditions on \(L\) and the law of \(X_{in}\), we can apply Varadhan’s lemma (cf. [9]) to get
\[
(3.6) \quad \lim_{\beta \to \infty} \left( -\frac{1}{\beta} \log \mathbb{E} e^{-\beta L(X_{in})} \right) = \inf_{\omega \in \Omega} L(X_{in}).
\]

However, as far as the authors know, standard proofs for Varadhan’s lemma do not yield a convergence rate. Hence, we try a different approach for a possible convergence rate in (3.6).

Recall that the set \(D \in \mathbb{R}^d\) is called a **\(d\)-dimensional closed domain** if it is a bounded finitely connected open set (in \(\mathbb{R}^d\)) plus its boundary, where the boundary is a Euclidean \((d - 1)\)-surface. One simple example of such \(D\) is a closed ball in \(\mathbb{R}^d\). In the sequel, let \(D\) be a \(d\)-dimensional closed domain.

**Lemma 3.3.** [18] Suppose that two functions \(\phi : D \to \mathbb{R}\) and \(h : D \to \mathbb{R}\) satisfy the following conditions:

1. \(h\) is positive and is of class \(C^2\).
2. \(\phi h^n\) is absolutely integrable over \(D\), \(n = 1, 2, \cdots\).
h has an absolutely maximum value at an interior point ξ of D and det (−∇^2 h(ξ)) > 0. 
(4) φ is continuous at ξ and φ(ξ) ≠ 0.

Then, we have
\[ \int_D \phi(x)[h(x)]^n \, dx \sim \left( \frac{2\pi}{n} \right)^{\frac{d}{2}} \frac{\phi(ξ)[h(ξ)]^n}{\sqrt{\det (−∇^2 \log h(ξ))}}, \quad n \to ∞. \]

Proof. We refer to Lemma 1 in [18] for details.

**Proposition 3.1.** Suppose that the law of X in is absolutely continuous with respect to the Lebesgue measure on \( \mathbb{R}^d \) and let f be a probability density function. Suppose that

(1) f is compactly supported.
(2) f is continuous at the global minimizer of L, namely \( X_∗ \), and \( f(X_*) > 0 \).
(3) L is \( C^2 \) and \( \det (\nabla^2 L(X_*)) > 0 \).

Then, we have
\[ -\frac{1}{β} \log \mathbb{E} e^{-βL(X_∞)} = L(X_*) + \frac{d \log β}{2} + O \left( \frac{1}{β} \right), \quad β \to ∞. \]

Proof. Let D be any closed ball containing the support of f. We set
\[ φ(x) := f(x) \quad \text{and} \quad h(x) := e^{-L(x)}. \]

For the above pair \((φ, h)\), we will check that the assumptions in Lemma 3.3 hold. Note that
\[ \det (−∇^2 h(X_*)) = \det \left( e^{-L(X_*)}(∇^2 L(X_*) - (∇L \otimes ∇L)(X_*))\right) \]
\[ = e^{-dL(X_*)} \det (∇^2 L(X_*)) > 0. \]

The rest of the assumptions can be checked straightforwardly. By Lemma 3.3, we have
\[ \lim_{β \to ∞} \sqrt{\det (∇^2 L(X_*))} \mathbb{E} e^{-βL(X_∞)} \left( \frac{2\pi}{n} \right)^{\frac{d}{2}} f(X_*) e^{-βL(X_*)} = 1. \]

By taking logarithms on both sides of (3.7), we get
\[ \log \mathbb{E} e^{-βL(X_∞)} - \frac{d}{2} \log \left( \frac{2\pi}{β} \right) - \log f(X_*) + \frac{1}{β} \log (∇^2 L(X_*)) = O(1). \]

We multiply \(-\frac{1}{β}\) on both sides to obtain
\[ -\frac{1}{β} \log \mathbb{E} e^{-βL(X_∞)} = L(X_*) + \left( -\frac{d}{2} \log (2\pi) - \log f(X_*) + \frac{1}{2} \log (∇^2 L(X_*)) \right) \frac{1}{β} + \frac{d \log β}{2} + O \left( \frac{1}{β} \right). \]

Hence, one has the desired estimate:
\[ -\frac{1}{β} \log \mathbb{E} e^{-βL(X_∞)} = L(X_*) + \frac{d \log β}{2} + O \left( \frac{1}{β} \right), \]

for a sufficiently large \( β \).

\[ \text{(Proof of Theorem 3.2)}: \] First, we claim:
\[ \text{essinf}_{ω ∈ Ω} L(X_∞) ≤ -\frac{1}{β} \log \mathbb{E} e^{-βL(X_∞)} - \frac{1}{β} \log ε. \]
Note that

\[
\frac{1}{N} \sum_{i=1}^{N} e^{-\beta L(X_{n+1}^i)} - \frac{1}{N} \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \\
= \frac{1}{N} \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \left( e^{-\beta (L(X_{n+1}^i) - L(X_n^i))} - 1 \right)
\]

(3.9)

\[
\geq \frac{1}{N} \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \left( -\beta \left(L(X_{n+1}^i) - L(X_n^i) \right) \right)
\]

\[
= -\frac{\beta}{N} \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \nabla L(cX_{n+1}^i + (1-c)X_n^i) \cdot (X_{n+1}^i - X_n^i),
\]

where we used a mean-value theorem with \( c \in (0, 1) \). We use definition of \( \bar{X}_n^* \) to see

\[
\left( \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \right) \bar{X}_n^* = \sum_{i=1}^{N} e^{-\beta L(X_n^i)} X_n^i, \quad \left( \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \right) \bar{x}^*_{n,l} = \sum_{i=1}^{N} e^{-\beta L(X_n^i)} x^*_{n,l}, \quad l = 1, \ldots, d.
\]

This yields

\[
\sum_{i=1}^{N} e^{-\beta L(X_n^i)} \nabla L(\bar{X}_n^*) \cdot (X_{n+1}^i - X_n^i)
\]

(3.10)

\[
= \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \nabla L(\bar{X}_n^*) \cdot \left( -\gamma (X_n^i - \bar{X}_n^*) - \sum_{l=1}^{d} (x^i_{n,l} - \bar{x}^*_{n,l}) \eta^i_{n,l} e_l \right)
\]

\[
= \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \nabla L(\bar{X}_n^*) \cdot \left( -\sum_{l=1}^{d} (x^i_{n,l} - \bar{x}^*_{n,l}) (\gamma + \eta^i_{n,l}) e_l \right) = 0.
\]
Combining (3.9) and (3.10) gives

\[(3.11)\]

\[
\frac{1}{N} \sum_{i=1}^{N} e^{-\beta L(X_{n+1}^i)} - \frac{1}{N} \sum_{i=1}^{N} e^{-\beta L(X_n^i)} 
\geq - \frac{\beta}{N} \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \nabla L(cX_{n+1}^i + (1 - c)X_n^i) \cdot (X_{n+1}^i - X_n^i)
\]

\[= - \frac{\beta}{N} \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \left( \nabla L(cX_{n+1}^i + (1 - c)X_n^i - \nabla L(\bar{X}_n)) \cdot (X_{n+1}^i - X_n^i) \right)
\]

\[= - \frac{\beta}{N} \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \times \left[ \int_0^1 \nabla^2 L \left( s(cX_{n+1}^i + (1 - c)X_n^i) + (1 - s)\bar{X}_n \right) : \left( cX_{n+1}^i + (1 - c)X_n^i - \bar{X}_n \right) ds \cdot (X_{n+1}^i - X_n^i) \right]
\]

\[\geq - \frac{\beta}{N} \sum_{i=1}^{N} e^{-\beta L(X_n^i)} \left[ \int_0^1 \left\| \nabla^2 L \left( s(cX_{n+1}^i + (1 - c)X_n^i) + (1 - s)\bar{X}_n \right) \right\|_2 ds \right.
\]

\[\times \left. \left| cX_{n+1}^i + (1 - c)X_n^i - \bar{X}_n \right| \left| X_{n+1}^i - X_n^i \right| \right]
\]

\[\geq - \frac{C_L \beta e^{-\beta L_m}}{N} \sum_{i=1}^{N} \left| cX_{n+1}^i + (1 - c)X_n^i - \bar{X}_n \right| \left| X_{n+1}^i - X_n^i \right|
\]

\[= - \frac{C_L \beta e^{-\beta L_m}}{N} \sum_{i=1}^{N} \left[ \sum_{l=1}^{d} (x_{n+1}^{i,l} - \bar{x}_n^{i,l})(1 - c\gamma - cr_n^i) e_l \right] \left[ - \sum_{l=1}^{d} (x_{n+1}^{i,l} - \bar{x}_n^{i,l})(\gamma + \eta_n^l) e_l \right]
\]

\[= - \frac{C_L \beta e^{-\beta L_m}}{N} \sum_{i=1}^{N} \sqrt{\sum_{l=1}^{d} (x_{n+1}^{i,l} - \bar{x}_n^{i,l})^2 (1 - c\gamma - cr_n^i)^2} \sqrt{\sum_{l=1}^{d} (x_{n+1}^{i,l} - \bar{x}_n^{i,l})^2 (\gamma + \eta_n^l)^2}.
\]

Set

\[g(r) := (1 - r\gamma - r\eta_n^l)^2, \quad 0 \leq r \leq 1.
\]

Then, we use the convexity of \(g\) to find

\[(1 - c\gamma - cr_n^i)^2 \leq \sup_{0 \leq r \leq 1} g(r) = \max\{g(0), g(1)\} \leq g(0) + g(1) = 1 + (1 - \gamma - \eta_n^l)^2.
\]

We substitute the above relation into (3.11) to obtain

\[(3.12)\]

\[
\frac{1}{N} \sum_{i=1}^{N} e^{-\beta L(X_{n+1}^i)} - \frac{1}{N} \sum_{i=1}^{N} e^{-\beta L(X_n^i)} 
\geq - \frac{C_L \beta e^{-\beta L_m}}{N} \sum_{i=1}^{N} \sqrt{\sum_{l=1}^{d} (x_{n+1}^{i,l} - \bar{x}_n^{i,l})^2 (1 + (1 - \gamma - \eta_n^l)^2)} \sqrt{\sum_{l=1}^{d} (x_{n+1}^{i,l} - \bar{x}_n^{i,l})^2 (\gamma + \eta_n^l)^2}.
\]
Taking expectations on the both sides of (3.12) using the Cauchy-Schwarz inequality leads to (3.13)

$$\frac{1}{N} \sum_{i=1}^{N} \mathbb{E} e^{-\beta L(X_{n,i})} \leq \frac{C_0}{N} \sum_{i=1}^{N} \mathbb{E} e^{-\beta L(X_{i})}$$

Hence

$$\frac{1}{N} \sum_{i=1}^{N} \mathbb{E} e^{-\beta L(X_{n,i})} \leq \frac{C_0}{N} \sum_{i=1}^{N} \mathbb{E} e^{-\beta L(X_{i})}$$

Taking expectations on the both sides of (3.12) using the Cauchy-Schwarz inequality leads to

$$\frac{1}{N} \sum_{i=1}^{N} \mathbb{E} e^{-\beta L(X_{n,i})} \leq \frac{C_0}{N} \sum_{i=1}^{N} \mathbb{E} e^{-\beta L(X_{i})}$$

Letting $n \to \infty$, we use Lemma 3.2 to find

$$\mathbb{E} e^{-\beta L(X_{\infty})} \geq \frac{1}{N} \sum_{i=1}^{N} \mathbb{E} e^{-\beta L(X_{i})}$$

We sum up (3.13) over $n$ to get

$$\frac{1}{N} \sum_{i=1}^{N} \mathbb{E} e^{-\beta L(X_{n,i})} \geq \frac{1}{N} \sum_{i=1}^{N} \mathbb{E} e^{-\beta L(X_{i})}$$

Letting $n \to \infty$, we use Lemma 3.2 to find

$$\mathbb{E} e^{-\beta L(X_{\infty})} \geq \frac{1}{N} \sum_{i=1}^{N} \mathbb{E} e^{-\beta L(X_{i})}$$

By taking logarithm to the both sides of the above relation yields the desired estimate (3.14).
Next, we apply Proposition 3.1 to obtain
\[
\inf_{\omega \in \Omega} L(X_{\infty}) \leq L(X_*) + \frac{d \log \beta}{2 \beta} + E(\beta),
\]
for some function \( E(\beta) = O\left(\frac{1}{\beta}\right) \). This completes the proof of Theorem 3.2.

4. Conclusion

In this paper, we presented a convergence study with an error estimate for a time-discrete consensus-based non-convex optimization algorithm, which includes three discrete-in-time algorithms used in [4]. For the continuous algorithm introduced in [4], convergence and error analysis was studied by the authors recently using the detailed structure of the algorithm and Itô’s stochastic analysis. However, for the discrete algorithm such analysis was not done in the aforementioned work [14]. The main reason for that was the lack of discrete analog of the Itô’s stochastic analysis which has been crucially used in the study of the continuous algorithm. Our error analysis employed in this work is based on the elementary and simple probability arguments together with the detailed structure of nonlinear interaction terms, and consequently provides the stability condition, convergence and an error analysis toward the global minimum for all three time-discrete algorithms implemented in [4]. Our analysis shows that these algorithms, under certain conditions on the parameters and with sufficiently well-chosen initial data, do converge to a point close to the global minimum for moderately high dimensional problems.
Appendix A. Error estimate under an alternative framework

In this subsection, we provide an alternative result for an error estimate for time-discrete CBO scheme (1.1) without using Laplace’s principle under a slightly different framework (B1) – (B2). Below, we present a framework for the objective function $L$, global minimum point $X_*$ and reference random variable $X_{in}$ as follows:

- **(B1):** Let $L = L(x)$ be a $C^2$-objective function satisfying the following relations:
  \[ L_m := \min_{x \in \mathbb{R}^d} L(x) > 0 \quad \text{and} \quad C_L := \sup_{x \in \mathbb{R}^d} \| \nabla^2 L(x) \|_2 < \infty, \]
  where $\| \cdot \|_2$ denotes the spectral norm.

- **(B2):** Let $X_{in}$ be a reference random variable associated with a law whose support $\hat{D}$ is compact and contains $X_*$. Note that the condition (B1) is exactly the same as (A1), whereas the condition (B2) is different from (A3) in which the probability measures associated with $X_{in}$ is absolutely continuous with respect to Lebesgue measure. Moreover, notice that this new framework does not need any condition on $\det(\nabla^2 L(X_*))$ as in (A2).

Next, we study how the common consensus state $X_\infty$ is close to the global minimum $X_*$ in suitable sense. Now, we are ready to provide an error estimate for the discrete CBO algorithm, which is analogous to Theorem 4.1 in [14] for the continuous case.

**Theorem A.1.** Suppose that the framework (B1) – (B2) holds, and parameters $\beta, \gamma, \zeta, \delta$ and the initial data $\{X_0^i\}$ satisfy

\[
\beta > 0, \quad \delta > 0, \quad (\gamma - 1)^2 + \zeta^2 < 1, \quad X_0^i \text{ i.i.d, } X_0^i \sim X_{in}, \quad \sup_{x \in \hat{D}} L(x) - L_m < \delta,
\]

\[
(1 - \varepsilon) \mathbb{E} \left[ e^{-\beta L(X_{in})} \right] \geq \frac{2C_L}{1 - e^{-1-(\gamma-1)^2-\zeta^2}} \beta e^{-\beta L_m} \sum_{l=1}^{d} \left( \mathbb{E}_{1 \leq i \leq N} (x_{0l}^i - \bar{x}_0^l)^2 \right),
\]

for some $0 < \varepsilon < 1$. Then, for a solution $\{X_i^n\}_{1 \leq i \leq N}$ to (1.1),

\[
\left| \text{essinf}_{\omega \in \Omega} L(X_\infty) - L_m \right| \leq \delta + \left| \frac{\log \varepsilon}{\beta} \right|.
\]

**Remark A.1.** Before we provide a proof, we give several comments on the result of this theorem.

1. In the proof of Theorem A.1, we will first derive the estimate:

\[
\text{essinf}_{\omega \in \Omega} L(X_\infty) \leq \sup_{x \in \hat{D}} L(x) - \frac{1}{\beta} \log \varepsilon.
\]

2. For any given $\delta > 0$, $\varepsilon > 0$ and $\beta > 0$, the conditions (A.1) can be attained with suitable $X_{in}$. To see this, we choose the law of $X_{in}$ such that $\hat{D}$ is a small neighborhood of a global minimum $X_*$ satisfying the following two relations:

\[
\sup_{x \in \hat{D}} L(x) - L_m < \delta,
\]
and

\[ 1 - \varepsilon \geq \frac{2C_L \sqrt{(1 + (1 - \gamma)^2 + \zeta^2)(\gamma^2 + \zeta^2)} \beta \left( \sup_{x \in \tilde{D}} L(x) - L_m \right) \beta L_m}{1 - e^{-\left(2\gamma - \sqrt{-\gamma^2 - \zeta^2}\right)}} \left( \text{diam}(\mathcal{R}_m) \right)^2, \]

where \( \mathcal{R}_m = [a_1, b_1] \times \cdots \times [a_d, b_d] \) is the smallest closed \( d \)-dimensional rectangle containing \( \tilde{D} \) so that

\[ (A.6) \quad \mathbb{E} \left[ \max_{1 \leq i \leq N} (x_0^{i,l} - \bar{x}_0^l)^2 \right] \leq |b_l - a_l|^2, \]

for each \( l = 1, \ldots, d \). Then, due to \( (A.6) \), the relation \( (A.5) \) implies the condition \( (A.4) \). Hence, we can apply the estimate \( (A.3) \) and \( (A.4) \) to get the desired error estimate:

\[ \text{essinf}_{\omega \in \Omega} L(X_\infty) \leq L_m + \left( \sup_{x \in \tilde{D}} L(x) - L_m \right) - \frac{1}{\beta} \log \varepsilon \leq L_m + \delta - \frac{\log \varepsilon}{\beta}. \]

Now we are ready to provide a proof of Theorem \( A.1 \). By the same way as in the proof of Theorem \( 3.2 \), we obtain

\[
\mathbb{E} e^{-\beta L(X_\infty)} \geq \frac{1}{N} \sum_{i=1}^{N} \mathbb{E} e^{-\beta L(X_0^i)} - 2C_L \sqrt{(1 + (1 - \gamma)^2 + \zeta^2)(\gamma^2 + \zeta^2)} \beta e^{-\beta L_m} \left( \sup_{l=1}^{d} \left( \mathbb{E} \max_{1 \leq i \leq N} (x_0^{i,l} - \bar{x}_0^l)^2 \right) \right) \geq \varepsilon \mathbb{E} e^{-\beta L(X_{\text{in}})}.
\]

Hence one has

\[
e^{-\beta \text{essinf}_{\omega \in \Omega} L(X_\infty)} = \mathbb{E} e^{-\beta \text{essinf}_{\omega \in \Omega} L(X_\infty)} \geq \mathbb{E} e^{-\beta L(X_{\infty})} \geq \varepsilon \mathbb{E} e^{-\beta L(X_{\text{in}})} \geq \varepsilon e^{-\beta \sup_{x \in \tilde{D}} L(x)}.
\]

Finally, we take logarithm to the both sides of the above relation to get the desired estimate \( (A.3) \).
