Abstract The invariants of rank 2 Joyce–Song semistable pairs over a Calabi–Yau threefold were computed in Sheshmani (Wall-crossing and invariants of higher rank stable pairs, Illinois J. Math., 2016), using the wall-crossing formula of Joyce–Song (A Theory of Generalized Donaldson–Thomas Invariants. Memoirs of American Mathematical Society, vol 217(1020), 2012), and Kontsevich and Soibelman (Stability structures, motivic Donaldson–Thomas invariants and cluster transformations. arXiv: 0811.2435, 2008). Such wallcrossing computations often depend on the combinatorial properties of certain elements of a Hall-algebra (these are the stack functions defined by Joyce (Configurations in abelian categories. II. Ringel–Hall algebras. Adv Math 210(2):635–706, 2007). These combinatorial computations become immediately complicated and hard to carry out, when studying higher rank stable pairs with rank > 2. The main purpose of this article is to introduce an independent approach to computation of rank 2 stable pair invariants, without applying the wallcrossing formula and rather by stratifying their corresponding moduli space and directly computing the weighted Euler characteristic of the strata. This approach may similarly be used to avoid complex combinatorial wallcrossing calculations in rank > 2 cases.

1 Introduction

The Donaldson–Thomas theory (DT in short) of a Calabi–Yau threefold $X$ is defined in [3, 17] via integration against the virtual fundamental class of the moduli space of ideal sheaves. In [13, 14], Pandharipande and Thomas introduced objects given by pairs $(F, s)$ where $F$ is a pure sheaf with one dimensional support together with a fixed Hilbert polynomial and $s \in H^0(X, F)$ is given as a section of $F$. The authors computed the invariants of stable pairs, using deformation theory and virtual fundamental classes.

Following their work, Joyce and Song defined a similar notion of a (twisted) stable pair, given by a sheaf $F$ and section map $s: \mathcal{O}(n) \rightarrow F$ where $n \gg 0$ was chosen to be a sufficiently large integer so that the cohomology vanishing condition $H^1(F(n)) = 0$ is satisfied. These stable pairs were equipped with a stability condition rather different than the one used in [13].

Definition 1 (Joyce–Song pair stability) Given a coherent sheaf $F$, let $p_F$ denote the reduced Hilbert polynomial of $F$ with respect to the ample line bundle $\mathcal{O}_X(1)$. A pair $(F, s: \mathcal{O}(−n) \rightarrow F)$ is called stable if the following conditions are satisfied:

- $p_{F'} \leq p_F$ for all proper subsheaves $F'$ of $F$ such that $F' \neq 0$.
- If $\phi$ factors through $F'$ ($F'$ a proper subsheaf of $F$), then $p_{F'} < p_F$.

In this article we refer to this stability as $\tilde{\tau}$-stability. For more on Joyce–Song stability look at [10, Definition 12.2].

One advantage in defining $\tilde{\tau}$-stability, is that it enables one to compute the generalized Donaldson–Thomas invariants with respect to the invariants of $\tilde{\tau}$-stable pairs. The generalized Donaldson–Thomas invariants could not be calculated using the machinery developed by Thomas in [17], since they were given by invariants of semistable sheaves (not just the stable ones!). After work of Joyce and Song an interesting question was whether one is able to study and compute the invariants of objects composed of a sheaf $F$ and multiple sections given by the morphism $s_1 \cdots s_r: \mathcal{O}^{\oplus r}(−n) \rightarrow F$ for $r > 1$ (we will later denote these by rank $r$ stable pairs for short). In [15], the author introduced the notion of highly frozen triples (same as rank $r$ stable pairs), and used the virtual localization technique introduced by Graber–Pandharipande [4] to compute their invariants over local Calabi–Yau threefolds (such as local $\mathbb{P}^1$). The objects studied in [15] (because of the stability condition chosen) were reminiscent of the higher rank analog of (a twisted version of) the Pandharipande–Thomas (PT in short) stable pairs [13]. In [16], the author studied the same higher rank objects, but equipped with the $\tilde{\tau}$-stability condition, and computed their invariants using the wallcrossing technique.

In this article we would like to introduce a direct method of calculation of such invariants, which involves first stratifying the moduli space of higher rank semistable pairs into disjoint components, where each stratum contains the stable rank 1 pairs and then computing the weighted Euler characteristic of the moduli space of higher
rank pairs with respect to the Euler characteristic of the rank 1 strata. In doing so, we need to first define an auxiliary category $\mathcal{B}_p$ (which was originally introduced by Joyce–Song [10, Section 13.1]). The objects in $\mathcal{B}_p$ are defined similar to the higher rank Joyce–Song pairs and they are classified basing on their numerical class $(\beta, r)$. Here, $\beta$ denotes the Chern character of $F$ and $r$ denotes the number of sections of $F$ being considered in the construction. The definition of the category $\mathcal{B}_p$ allows one to define weak stability conditions on $\mathcal{B}_p$ (look at Definition 6).

As we have shown in [16, Theorem 5.1], the moduli stack of weak semistable objects (we denote this by $\tilde{\tau}$-semistable) in $\mathcal{B}_p$ is closely related to the parameterizing moduli stack of higher rank $\tilde{\tau}$-semistable pairs, which enables us to obtain the following identity:

$$N^\beta_r (\tilde{\tau}) = (-1)^{\tau^2} B^a_p(X, \beta, r, \tilde{\tau}).$$

The left-hand side of (1) stands for invariants of $\tilde{\tau}$-semistable pairs and the right-hand side stands for invariants of $\tilde{\tau}$-semistable objects in $\mathcal{B}_p$ which are, roughly speaking, defined as the weighted Euler characteristic of their corresponding moduli stack. Therefore, using this identity, we aim at calculating the right-hand side of (1), using the stratification method mentioned above.

We show in this article that the result of our calculation agrees with the results obtained in [16]. In particular, we restrict our computations to the rank 2 pairs ($r = 2$), and very explicitly calculate their invariants in some examples. As we will see below, even though the computation of such invariants requires a detailed study of the strata involved in the moduli space, the advantage of the strategy used in here is that it is much more geometric and it avoids complicated combinatorics involved in the method of wallcrossing. Moreover, we suspect that the methods introduced in this article may be used to prove the integrality conjectures for the partition functions of the higher rank Joyce–Song invariants in special cases. Toda in [18] has used a similar stratification technique and provided an evidence of such integrality property, proposed by Kontsevich–Soibelman [12, Conjecture 6].

The auxiliary category $\mathcal{B}_p$

**Definition 2** Let $X$ be a nonsingular projective Calabi–Yau threefold equipped with an ample line bundle $\mathcal{O}_X(1)$. Let $\tau$ denote the Gieseker stability condition on the abelian category of coherent sheaves on $X$. Define $A_p$ to be the sub-category of coherent sheaves whose objects are zero sheaves and nonzero $\tau$-semistable sheaves with fixed reduced Hilbert polynomial $p$.\(^1\)

**Definition 3** Fix an integer $n$. Now define the category $\mathcal{B}_p$ to be the category whose objects are triples $(F, V, \phi)$, where $F \in \text{Obj}(A_p)$, $V$ is a finite dimensional $\mathbb{C}$-vector space, and $\phi: V \to \text{Hom}(\mathcal{O}_X(-n), F)$ is a $\mathbb{C}$-linear map. Given $(F, V, \phi)$ and $(F', V', \phi')$ in $\mathcal{B}_p$, define morphisms $(F, V, \phi) \to (F', V', \phi')$ in $\mathcal{B}_p$ to be pairs\(^1\)

\(^1\) Look at [10, Definition 13.1] for more detail.
of morphisms \((f, g)\), where \(f: F \to F'\) is a morphism in \(\mathcal{A}_p\) and \(g: V \to V'\) is a \(\mathbb{C}\)-linear map such that the following diagram commutes:

\[
\begin{array}{ccc}
V & \xrightarrow{\phi} & \text{Hom}(\mathcal{O}_X(-n), F) \\
\downarrow{g} & & \downarrow{f} \\
V' & \xrightarrow{\phi'} & \text{Hom}(\mathcal{O}_X(-n), F').
\end{array}
\]

Our definition of the category \(\mathcal{B}_p\) is compatible with that of [10, Definition 13.1]. Now we define the numerical class of objects in \(\mathcal{B}_p\) based on [10, Section 3.1].

**Definition 4** Define the Grothendieck group \(K(\mathcal{B}_p) = K(\mathcal{A}_p) \oplus \mathbb{Z}\), where \(K(\mathcal{A}_p)\) is given by the image of \(K_0(\mathcal{A}_p)\) in \(K(\text{Coh}(X)) = K^{\text{num}}(\text{Coh}(X))\). Let \(\mathcal{C}(\mathcal{A}_p)\) denote the positive cone of \(\mathcal{A}_p\) defined as

\[
\mathcal{C}(\mathcal{A}_p) = \{ E \in K^{\text{num}}(\mathcal{A}_p) : 0 \neq E \in \mathcal{A}_p \}\).

Now, given \((F, V, \phi) \in \mathcal{B}_p\), we write \([F, V, \phi] = ([F], \dim V)\) and define the positive cone of \(\mathcal{B}_p\) by

\[
\mathcal{C}(\mathcal{B}_p) = \{ (\beta, d) : \beta \in \mathcal{C}(\mathcal{A}_p), d \geq 0 \text{ or } \beta = 0 \text{ and } d > 0 \}\).

We state the following results by Joyce and Song without proof.

**Lemma 1** ([10, Lemma 13.2]) The category \(\mathcal{B}_p\) is abelian and \(\mathcal{B}_p\) satisfies the condition that if \([F] = 0 \in K(\mathcal{A}_p)\) then \(F \cong 0\). Moreover, \(\mathcal{B}_p\) is noetherian and artinian and the moduli stacks \(\mathcal{M}(\beta, d)\) are of finite type for all \((\beta, d) \in \mathcal{C}(\mathcal{B}_p)\).

**Remark 1** The category \(\mathcal{A}_p\) embeds as a full and faithful sub-category in \(\mathcal{B}_p\) by \(F \mapsto (F, 0, 0)\). Moreover, it is shown in [10, Equation (13.3)] that every object \((F, V, \phi)\) sits in a short exact sequence

\[
0 \to (F, 0, 0) \to (F, V, \phi) \to (0, V, 0) \to 0.
\]

Next we recall the definition of weak (semi)stability for a general abelian category \(\mathcal{A}\).

**Definition 5** Let \(\mathcal{A}\) be an abelian category. Let \(K(\mathcal{A})\) be the quotient of \(K_0(\mathcal{A})\) by some fixed group. Let \(\mathcal{C}(\mathcal{A})\) be the positive cone of \(\mathcal{A}\). Suppose \((T, \leq)\) is a totally ordered set and \(\tau: \mathcal{C}(\mathcal{A}) \to T\) is a map. We call \((\tau, T, \leq)\) a stability condition on \(\mathcal{A}\) if whenever \(\alpha, \beta, \gamma \in \mathcal{C}(\mathcal{A})\) with \(\beta = \alpha + \gamma\) then either

\[
\tau(\alpha) < \tau(\beta) < \tau(\gamma) \quad \text{or} \quad \tau(\alpha) > \tau(\beta) > \tau(\gamma) \quad \text{or} \quad \tau(\alpha) = \tau(\beta) = \tau(\gamma).
\]

We call \((\tau, T, \leq)\) a weak stability condition on \(\mathcal{A}\) if whenever \(\alpha, \beta, \gamma \in \mathcal{C}(\mathcal{A})\) with \(\beta = \alpha + \gamma\) then either \(\tau(\alpha) \leq \tau(\beta) \leq \tau(\gamma)\) or \(\tau(\alpha) \geq \tau(\beta) \geq \tau(\gamma)\). For such \((\tau, T, \leq)\), we say that a nonzero object \(E\) in \(\mathcal{A}\) is
- \( \tau \)-semistable if for all \( S \subset E \), where \( S \neq 0 \), we have \( \tau([S]) \leq \tau([E/S]) \),
- \( \tau \)-stable if for all \( S \subset E \), where \( S \neq 0 \), we have \( \tau([S]) < \tau([E/S]) \),
- \( \tau \)-unstable if it is not \( \tau \)-semistable.\(^2\)

Now we apply the definition of weak stability conditions to the category \( \mathcal{B}_p \).

**Definition 6** Define the weak stability condition \((\tilde{\tau}, \tilde{T}, \preceq)\) on \( \mathcal{B}_p \) by \( \tilde{T} = \{0, 1\} \) with the natural order \( 0 < 1 \), and \( \tilde{\tau}(\beta, d) = 0 \) if \( d = 0 \) and \( \tilde{\tau}(\beta, d) = 1 \) if \( d > 0 \).

Definition 6 is compatible with that of [10, Definition 13.5].

---

**Moduli stack of objects in \( \mathcal{B}_p \)**

Before constructing the moduli stack of objects in \( \mathcal{B}_p \), we would like to provide a different description of objects in \( \mathcal{B}_p \) as complexes in the derived category. This makes it easier to understand the strategy to construct their moduli spaces. By [10, Lemma 13.2], there exists a natural embedding functor \( \mathcal{F}: \mathcal{B}_p \to D(X) \) which takes \( (F, V, \phi_V) \in \mathcal{B}_p \) to an object in the derived category given by

\[
\cdots \to 0 \to V \otimes \mathbb{O}_X(-n) \to F \to 0 \to \cdots,
\]

where \( V \otimes \mathbb{O}_X(-n) \) and \( F \) sit in degree \(-1\) and \( 0 \). Assume that \( \dim V = r \). In that case \( V \otimes \mathbb{O}_X(-n) \cong \mathbb{O}_X(-n)^{\oplus r} \). Therefore, one may view an object \( (F, V, \phi_V) \in \mathcal{B}_p \) as an object in an abelian sub-category of the derived category, given as \( \mathbb{O}_X(-n)^{\oplus r} \to F \). Now let us use this perspective and define the notion of flat families for objects in \( \mathcal{B}_p \).

**Definition 7** Fix a parameterizing scheme of finite type \( S \). Let \( \pi_X: X \times S \to X \) and \( \pi_S: X \times S \to S \) denote the natural projections. Use the natural embedding functor \( \mathcal{F}: \mathcal{B}_p \to D(X) \) in [10, Lemma 13.2]. Define the \( S \)-flat family of objects in \( \mathcal{B}_p \) of type \((\beta, r)\) as a complex

\[
\pi_S^* M \otimes \pi_X^* \mathbb{O}_X(-n) \xrightarrow{\psi_S} \mathcal{F}
\]

sitting in degree \(-1\) and \( 0 \), such that \( \mathcal{F} \) is given by an \( S \)-flat family of semistable sheaves with fixed reduced Hilbert polynomial \( p \) with \( \text{ch}(F) = \beta \) and \( M \) a vector bundle of rank \( r \) over \( S \). A morphism between two such \( S \)-flat families is given by a morphism between the complexes

\[
\pi_S^* M \otimes \pi_X^* \mathbb{O}_X(-n) \xrightarrow{\psi_S} \mathcal{F} \quad \text{and} \quad \pi_S^* M' \otimes \pi_X^* \mathbb{O}_X(-n) \xrightarrow{\psi_S'} \mathcal{F}',
\]

\(^2\) For more detail on Definition 5 look at [10, Definition 3.5].
Moreover an isomorphism between two such $S$-flat families in $\mathcal{B}_p$ is given by an isomorphism between the associated complexes

\[
\begin{align*}
\pi^*_SM \otimes \pi^*_X\mathcal{O}_X(-n) & \xrightarrow{\psi_S} \mathcal{F} \\
\pi^*_SM' \otimes \pi^*_X\mathcal{O}_X(-n) & \xrightarrow{\psi'_S} \mathcal{F}'.
\end{align*}
\]

From now on, by objects in $\mathcal{B}_p$ we mean the objects which lie in the image of the natural embedding functor $\mathcal{B}_p \to D(X)$. Moreover, by the $S$-flat family of objects in $\mathcal{B}_p$ and their morphisms (or isomorphisms) we mean their corresponding definitions as stated in Definition 7.

Now we define the rigidified objects in $\mathcal{B}_p$. These are only going to provide the means for construction of moduli stack of objects in $\mathcal{B}_p$ as a quotient stack.

1.1 Rigidified objects and their realization in the derived category

As stated in Definition 7, the objects in $\mathcal{B}_p$ are defined so that the sheaf sitting in degree $-1$ is given by a trivial vector bundle of rank $r$ isomorphic to $\mathcal{O}_X^\oplus r$. However we have not fixed any choice of such trivialization. Below we will define closely related objects, which we denote by rigidified objects in $\mathcal{B}_p$, by fixing a choice of the trivialization of $\mathcal{O}_X^\oplus r$. These objects are essential for our construction, as their moduli stack forms a $GL_r(\mathbb{C})$-torsor over the (to be defined) moduli stack of objects in $\mathcal{B}_p$. Therefore our plan is to essentially construct the moduli stack of objects in $\mathcal{B}_p$ as the stacky quotient of the moduli stack of rigidified objects in $\mathcal{B}_p$, where the group we take the quotient with is $GL_r(\mathbb{C})$.

**Definition 8** Fix a positive integer $r$ and define the sub-category $\mathcal{B}_p^R \subset \mathcal{B}_p$ to be the category of rigidified objects in $\mathcal{B}_p$ of rank $r$ whose objects are defined by tuples $(F, C^\oplus r, \rho)$ where $F$ is a coherent sheaf with reduced Hilbert polynomial $p$, $ch(F) = \beta$ and $\rho: C^r \to \text{Hom}(\mathcal{O}_X(-n), F)$. Given two rigidified objects of fixed type $(\beta, r)$ as $(F, C^\oplus r, \rho)$ and $(F', C^\oplus r, \rho')$ in $\mathcal{B}_p^R$, define morphisms $(F, C^\oplus r, \rho) \to (F', C^\oplus r, \rho')$ to be given by a morphism $f: F \to F'$ in $\mathcal{A}_p$ such that the following
diagram commutes:

\[
\begin{array}{ccc}
\mathbb{C}^{\oplus r} & \xrightarrow{\rho} & \text{Hom}(\mathcal{O}_X(-n), F) \\
\downarrow \text{id} & & \downarrow f \\
\mathbb{C}^{\oplus r} & \xrightarrow{\rho'} & \text{Hom}(\mathcal{O}_X(-n), F').
\end{array}
\]

**Remark 2** Similar to before, there exists a natural embedding functor \( \mathfrak{g}^R: \mathcal{B}_p^R \to D(X) \) which takes \((F, \mathbb{C}^{\oplus r}, \rho) \in \mathcal{B}_p^R \) to an object in the derived category given by \( \cdots \to 0 \to \mathbb{C}^{\oplus r} \otimes \mathcal{O}_X(-n) \to F \to 0 \to \cdots \), where \( \mathbb{C}^{\oplus r} \otimes \mathcal{O}_X(-n) \) sits in degree \(-1 \) and \( F \) sits in degree \( 0 \). One may view an object in \( \mathcal{B}_p^R \) as a complex \( \phi: \mathcal{O}_X^r(-n) \to F \) such that the choice of trivialization of \( \mathcal{O}_X^r(-n) \) is fixed.

**Definition 9** Fix a parametrizing scheme of finite type \( S \). Use the natural embedding functor \( \mathfrak{g}^R: \mathcal{B}_p^R \to D(X) \) in Remark 2. An \( S \)-flat family of objects of type \((\beta, r)\) in \( \mathcal{B}_p^R \) is given by a complex

\[
\pi_S^*\mathcal{O}_S^r \otimes \pi_X^*\mathcal{O}_X(-n) \xrightarrow{\psi_S} \mathcal{F}
\]
sitting in degree \(-1\) and \( 0 \) such that \( \mathcal{F} \) is given by an \( S \)-flat family of semistable sheaves with fixed reduced Hilbert polynomial \( p \) with \( \text{ch}(\mathcal{F}_s) = \beta \) for all \( s \in S \). A morphism between two such \( S \)-flat families in \( \mathcal{B}_p^R \) is given by a morphism between the complexes

\[
\pi_S^*\mathcal{O}_S^r \otimes \pi_X^*\mathcal{O}_X(-n) \xrightarrow{\psi_S} \mathcal{F} \quad \text{and} \quad \pi_S^*\mathcal{O}_S^r \otimes \pi_X^*\mathcal{O}_X(-n) \xrightarrow{\psi'_S} \mathcal{F}'.
\]

Moreover an isomorphism between two such \( S \)-flat families in \( \mathcal{B}_p^R \) is given by an isomorphism between the associated complexes

\[
\pi_S^*\mathcal{O}_S^r \otimes \pi_X^*\mathcal{O}_X(-n) \xrightarrow{\psi_S} \mathcal{F} \quad \text{and} \quad \pi_S^*\mathcal{O}_S^r \otimes \pi_X^*\mathcal{O}_X(-n) \xrightarrow{\psi'_S} \mathcal{F}'.
\]

Similar to the way that we treated objects in \( \mathcal{B}_p \), from now on by objects in \( \mathcal{B}_p^R \) we mean the objects which lie in the image of the natural embedding functor \( \mathfrak{g}^R: \mathcal{B}_p^R \to D(X) \) in Remark 2. Moreover by the \( S \)-flat family of objects in \( \mathcal{B}_p^R \) and their morphisms (or isomorphisms) we mean the corresponding definitions as stated in Definition 9.
**Notation 1** In what follows we define $\mathcal{M}^{(\beta, r)}$ (\$\mathcal{M}^{(\beta, r)}_B\$ respectively) to be the moduli functors from $\text{Sch} / C \to \text{Groupoids}$ which send a $C$-scheme $S$ to the groupoid of $S$-flat family of objects of type $(\beta, r)$ in $\mathcal{B}_p$ (\$\mathcal{B}_p\$ respectively).

We will show that these moduli functors (as groupoid valued functors) are equivalent to algebraic quotient stacks. We will also show that the moduli stack $\mathcal{M}^{(\beta, r)}_B$ is given by a stacky quotient of $\mathcal{M}^{(\beta, r)}_B$ by $GL_r(C)$.

1.2 The underlying parameter scheme

According to Definition 3, an object in the category $A_p$ consists of semistable sheaves with fixed reduced Hilbert polynomial $p$. Note that having fixed a polynomial (in variable $t$) $p(t)$ as the reduced Hilbert polynomial of $F$ means that the Hilbert polynomial of $F$ can yet be chosen as $P_F(t) = kp(t)/d!$ for different values of $k$ where $d'$ is the dimension of $F$. However here we make an assumption that there are only finitely many possible values $k = 0, 1, \ldots, N$ for which our computation makes sense. We explain the motivation behind this assumption further below.

Our analysis inherits this finiteness property directly from applying [10, Proposition 13.7], where the authors show that there are only finitely many nontrivial contributions to their wallcrossing computation which are induced by objects, whose underlying sheaves could only have finitely many fixed Hilbert polynomials. In other words, according to [10, Proposition 13.7], it suffices to consider Hilbert polynomials $P_F(t) = kp(t)/d!$ induced by $p$ and only finitely many values of $k = 1, 2, \ldots, N$ for some $N > 0$. Similarly, for us there would only be finitely many such $k$ for which (1) holds true, which justifies the reason behind our assumption.

On the other hand, as discussed in [6, Theorem 3.37], the family of Gieseker-semistable sheaves $F$ on $X$ such that $F$ has a fixed Hilbert polynomial is bounded. Therefore, the family of coherent sheaves with finitely many fixed Hilbert polynomials is also bounded. We will use this boundedness property in our construction of parameterizing moduli stacks.

Now fix the Hilbert polynomial $P_F(t) = P$ as above and use the fact that, given a bounded family $\mathcal{F}$ of coherent sheaves with fixed Hilbert polynomial $P$ (here $F$ denotes a member of the family $\mathcal{F}$), there exists an upper bound for their Castelnuovo–Mumford regularity, given by the integer $m$, such that for each member $F$ of $\mathcal{F}$ the twisted sheaf $F(m')$ is globally generated for all $m' \geq m$. Fix such $m'$ and let $V$ be the complex vector space of dimension $d = P(m')$ given by $V = H^0(F \otimes \mathcal{O}_X(m'))$. Twisting the sheaf $F$ by the fixed large enough integer $m'$ would ensure one to get a surjective morphism of coherent sheaves $V \otimes \mathcal{O}_X(-m') \to F$. One can then construct a scheme parametrizing the flat quotients of $V \otimes \mathcal{O}_X(-m')$ with fixed given Hilbert polynomial $P$. This by usual arguments provides us with Grothendieck’s Quot-scheme. Here to shorten the notation we use $\Omega$ to denote $\text{Quot}_P(V \otimes \mathcal{O}_X(-m'))$. 
Denote by $Q^{ss} \subset \Omega$ the sublocus of Gieseker-semistable ($\tau$-semistable for short) sheaves $F$ with fixed Hilbert polynomial $P$.

**Definition 10** Let $n$ in Definition 7 be given so that $n \gg m'$. Define $\mathcal{P}$ over $Q^{ss}$ to be a bundle whose fibers parameterize $H^0(F(n))$. The fibers of the bundle $\mathcal{P}^{Br}$ over each point $[F] = \{p\}$, where $p \in Q^{ss}$, parameterize $H^0(F(n))^{Br}$. In other words, the fibers of $\mathcal{P}^{Br}$ parameterize the maps $O_X^{Br}(-n) \to F$ (which define the complexes representing the objects in $\mathcal{B}_p^R$).

There exists a right action of $GL(V)$ (where $V$ is as above) on the Quot-scheme $\Omega$ which induces an action on $Q^{ss}$, after restriction to the open subscheme of $\tau$-semistable sheaves. It is trivially seen that the action of $GL(V)$ on $Q^{ss}$ induces a right action on $\mathcal{P}^{Br}$. However note that, since we have fixed the trivialization of $O_X(n)$ for the objects in $\mathcal{B}_p^R$, there exists also an extra action of $GL_r(C)$ on $\mathcal{P}^{Br}$ which is described as follows. Let $[O_X^{Br}(-n) \to F]$ be given as a point in $\mathcal{P}^{Br}$. Let $\psi \in GL_r(C)$ be the map given by $\psi: O_X(-n)^{Br} \to O_X(-n)^{Br}$. The action of $GL_r(C)$ on $\mathcal{P}^{Br}$ is defined via precomposing the sections of $F$ with $\psi$ as shown in the diagram below:

![Diagram](Note that, by the Grothendieck–Riemann–Roch theorem, fixing a polarization over $X$ and the Chern character of sheaves as $\text{ch}(F) = \beta$, induces the fixed Hilbert polynomial for such $F$. Therefore this is the reason why we index our parameterizing moduli stacks by $(\beta, r)$ instead of $(P, r)$.

1.3 Artin stacks $\mathcal{M}^{(\beta, r)}_{\mathcal{B}_p}$ and $\mathcal{M}^{(\beta, r)}_{\mathcal{B}_p^{Br}}$

By Definitions 7 and 9, the construction of moduli stack of objects in $\mathcal{B}_p$ and $\mathcal{B}_p^{Br}$ is done similar to [15, Section 5].

**Theorem 1** Let $\mathcal{P}^{Br}$ be as in Definition 10. Then the following statements hold true:

(i) Let

\[
\begin{bmatrix}
\mathcal{P}^{Br} \\
GL(V)
\end{bmatrix}
\]

be the stack theoretic quotient of $\mathcal{P}^{Br}$ by $GL(V)$. Then, there exists an isomorphism of stacks

\[
\mathcal{M}^{(\beta, r)}_{\mathcal{B}_p^{Br}} \cong \begin{bmatrix}
\mathcal{P}^{Br} \\
GL(V)
\end{bmatrix}.
\]
In particular, $\mathcal{M}_{2p}^{(\beta,r)}$ is an Artin stack.

(ii) The moduli stack $\mathcal{M}_{2p}^{(\beta,r)}$ is a $\text{GL}_r(\mathbb{C})$-torsor over $\mathcal{M}_{2p}^{(\beta,r)}$. In particular, there exists an isomorphism of stacks

$$\mathcal{M}_{2p}^{(\beta,r)} \cong \frac{\mathcal{M}_{2p}^{(\beta,r)}}{\text{GL}_r(\mathbb{C})}.$$ 

(iii) It is true that locally in the flat topology

$$\mathcal{M}_{2p}^{(\beta,r)} \cong \mathcal{M}_{2p}^{(\beta,r)} \times \frac{\text{Spec}(\mathbb{C})}{\text{GL}_r(\mathbb{C})}.$$ 

This isomorphism does not hold true globally unless $r = 1$.

**Proof** The proofs of parts (i), (ii) are essentially the same as [15, Proposition 3.3, Remark 3.4, Theorems 3.5]. Now we prove part (iii) by showing that there exists a forgetful map $\pi: \mathcal{M}_{2p}^{(\beta,r)} \rightarrow \mathcal{M}_{2p}^{(\beta,r)}$ which induces a map from

$$\mathcal{M}_{2p}^{(\beta,r)} \times \frac{\text{Spec}(\mathbb{C})}{\text{GL}_r(\mathbb{C})}$$

to $\mathcal{M}_{2p}^{(\beta,r)}$ and show that this map has an inverse locally but not globally unless $r = 1$.

First we prove the claim for $r = 1$. GL$_1(\mathbb{C}) = \mathbb{G}_m$. For a $\mathbb{C}$-scheme $S$, an $S$-point of

$$\mathcal{M}_{2p}^{(\beta,1)}$$

is identified with the data $(O_X^S(-n) \rightarrow \mathcal{T}, L_S)$, where $L_S$ is a $\mathbb{G}_m$ line bundle over $S$. Let $\pi_S: X \times S \rightarrow S$ be the natural projection onto the second factor. There exists a map that sends this point to an $S$-point $p \in \mathcal{M}_{2p}^{(\beta,1)}$ which is obtained by tensoring with $L_S$, i.e.

$$(O_X^S(-n) \boxtimes L_S) \rightarrow \mathcal{T} \times \pi^*_S L_S.$$ 

Note that tensoring $O_X^S(-n)$ with $\pi^*_S L_S$ does not change the fact that fiber by fiber $O_{X \times S}(-n)(s) \boxtimes L_S$ is identified with $O_X(-n) \boxtimes L_S$. Moreover, there exists a section map

$$s: \mathcal{M}_{2p}^{(\beta,1)} \rightarrow \mathcal{M}_{2p}^{(\beta,1)} \times \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m}.$$ 

Simply take an $S$-point $[O_X(-n) \boxtimes L_S \rightarrow \mathcal{T}] \in (\mathcal{M}_{2p}^{(\beta,1)})(S)$ and send it to an $S$-point in

$$\left(\mathcal{M}_{2p}^{(\beta,1)} \times \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m}\right)(S).$$
by the map
\[
\left[ O_X(-n) \boxtimes \mathcal{L}_S \to \mathcal{F} \right] \mapsto \left( \left[ O_{X \times S}(-n) \to \mathcal{F} \otimes \pi_S^* \mathcal{L}_S^{-1} \right], \mathcal{L}_S \right).
\]
Note that since \( \mathcal{L}_S \) is a line bundle over \( S \) then it is invertible and hence a section map is always well-defined and \( \mathcal{M}^{(\beta, 1)}_{2, p} \) is a \( \mathbb{G}_m \)-gerbe over \( \mathcal{M}^{(\beta, 1)}_{2, p} \). Now let \( r > 1 \). It is left to show that there exists a map from
\[
\mathcal{M}^{(\beta, r)}_{2, p} \times \left[ \text{Spec} \mathbb{C} \over \text{GL}_r \mathbb{C} \right] \]
to \( \mathcal{M}^{(\beta, r)}_{2, p} \) and this map does not have an inverse (section map) globally. To proceed further, we state the following definition.

**Definition 11** Consider a stack \( \mathcal{Y}, p : \mathcal{Y} \to \text{Sch} / \mathbb{C} \). Given two morphisms of stacks \( \pi_1 : \mathcal{X} \to \mathcal{Y} \) and \( \pi_2 : \mathcal{X}' \to \mathcal{Y} \), the fibered product of \( \mathcal{X} \) and \( \mathcal{X}' \) over \( \mathcal{Y} \) is defined by the category whose objects are defined by triples \( (x, x', \alpha) \), where \( x \in \mathcal{X} \) and \( x' \in \mathcal{X}' \) respectively and \( \alpha : \pi_1(x) \to \pi_2(x') \) is an arrow in \( \mathcal{Y} \) such that \( p \circ \alpha = \text{id} \). Moreover, the morphisms \( (x, x'; \alpha) \to (y, y'; \beta) \) are defined by the tuple \( (\phi : x \to y, \psi : x' \to y') \) such that
\[
\pi_1(\psi) \circ \alpha = \beta \circ \pi_2(\phi) : P_E(x) \to P_E(y).
\]
Now observe that for \( r > 1 \), there exists a forgetful map
\[
\pi : \mathcal{M}^{(\beta, r)}_{2, p} \to \mathcal{M}^{(\beta, r)}_{2, p}
\]
which over \( S \)-points takes \( [O_X(-n) \boxtimes O_S^{\otimes r} \to \mathcal{F}] \) (see Definition 9) to \( [M \boxtimes O_X(-n) \to \mathcal{F}] \), where \( M \) is defined in Definition 7. Moreover, there exists a map
\[
g' : \mathcal{M}^{(\beta, r)}_{2, p} \to \text{BGL}_r \mathbb{C}
\]
which sends \( [M \boxtimes O_X(-n) \to \mathcal{F}] \) to \( M \) by forgetting \( \mathcal{F} \). Finally there exists the natural projection
\[
i : \text{Spec} \mathbb{C} \to \left[ \text{Spec} \mathbb{C} \over \text{GL}_r \mathbb{C} \right] = \text{BGL}_r \mathbb{C}.
\]
It follows directly from Definition 11 that the diagram
\[
\begin{array}{ccc}
\mathcal{M}^{(\beta, r)}_{2, p} & \xrightarrow{\pi} & \text{Spec} \mathbb{C} \\
\downarrow & & \downarrow i \\
\mathcal{M}^{(\beta, r)}_{2, p} & \xrightarrow{g'} & \text{BGL}_r \mathbb{C}
\end{array}
\]
is a fibered diagram and
\[ \mathcal{M}(\beta, r)_{\mathcal{B}^r_p} = \mathcal{M}(\beta, r)_{\mathcal{B}^r_p} \times_{\mathcal{B}^r_p} \text{Spec}(\mathbb{C}). \]

However, one cannot use the same argument used for the case of \( r = 1 \) to conclude that there exists a section map
\[ s: \mathcal{M}(\beta, r)_{\mathcal{B}^r_p} \to \mathcal{M}(\beta, r)_{\mathcal{B}^r_p} \times_{\mathcal{B}^r_p} \text{Spec}(\mathbb{C}), \]

since the \( S \)-point of \( \mathcal{B}^r_p \) is a \( \mathcal{B}^r_p \) bundle over \( S \) and this vector bundle is trivializable locally but not globally. Therefore locally one may think of \( \mathcal{M}(\beta, r)_{\mathcal{B}^r_p} \) as isomorphic to
\[ \mathcal{M}(\beta, r)_{\mathcal{B}^r_p} \times_{\mathcal{B}^r_p} \text{Spec}(\mathbb{C}), \]

but not globally.

**Definition 12** Define \( \mathcal{M}(\beta, r)_{\mathcal{B}^r_p, ss} \) as the substack of \( \mathcal{M}(\beta, r)_{\mathcal{B}^r_p} \) parameterizing \( \mathcal{B} \)-semi-stable objects in \( \mathcal{B}^r_p \). Since \( \mathcal{M}(\beta, r)_{\mathcal{B}^r_p} \) is of finite type \([10, \text{Lemma 13.2}]\), then \( \mathcal{M}(\beta, r)_{\mathcal{B}^r_p, ss} \) is of finite type for all \( (\beta, r) \in \mathcal{C}(\mathcal{B}^r_p) \).

2 Stack function identities in the Ringel–Hall algebra

We review here some basic facts about the stack functions in the Ringel–Hall algebras. Let \( \mathcal{M} \) be an Artin \( \mathbb{C} \)-stack with affine geometric stabilizers. Consider pairs \((\mathcal{R}, \rho)\), where \( \mathcal{R} \) is given by a finite type Artin \( \mathbb{C} \)-stack with affine geometric stabilizers and \( \rho = \mathcal{R} \to \mathcal{M} \) is a 1-morphism. Now define an equivalence relation for such pairs, where \((\mathcal{R}, \rho)\) and \((\mathcal{R}', \rho')\) are called equivalent if there exists a 1-morphism \( \varphi: \mathcal{R} \to \mathcal{R}' \) such that \( \varphi \circ \rho \) and \( \rho \) are 2-isomorphic 1-morphisms \( \mathcal{R} \to \mathcal{M} \). Joyce and Song in \([10, \text{Section 2.2}]\) define the space of stack functions \( \text{SF}(\mathcal{M}, \chi, \mathcal{Q}) \) as the \( \mathcal{Q} \)-vector space generated by the above equivalence classes of pairs \([\mathcal{R}, \rho]\) such that the following relations are imposed:

(a) Given a closed substack \((\mathcal{G}, \rho|_{\mathcal{G}}) \subset (\mathcal{R}, \rho)\), we have
\[ [(\mathcal{R}, \rho)] = [(\mathcal{G}, \rho|_{\mathcal{G}})] + [(\mathcal{R} \setminus \mathcal{G}, \rho|_{\mathcal{R} \setminus \mathcal{G}})]. \]

(b) Let \( \mathcal{U} \) denote a quasi-projective \( \mathbb{C} \)-variety, \( \pi: \mathcal{R} \times U \to \mathcal{R} \) be the natural projection and \( \rho: \mathcal{R} \to \mathcal{M} \) be a 1-morphism. Then
\[ [\mathcal{R} \times \mathcal{U}, \rho \circ \pi_{\mathcal{R}}] = \chi(\mathcal{U})[(\mathcal{R}, \rho)]. \]
(c) Assume $\mathcal{M} \cong [X/G]$, where $X$ is a quasiprojective $\mathbb{C}$-variety and $G$ a very special algebraic $\mathbb{C}$-group acting on $X$ with maximal torus $T^G$, then we have

$$[\mathcal{M}, \rho] = \sum_{Q \in \mathcal{Q}(G, T^G)} F(G, T^G, Q)\left(\left([X/Q], \rho \circ i_Q\right)\right),$$

where the rational coefficients $F(G, T^G, Q)$ have a complicated definition explained in [9, Section 6.2]. Here $\mathcal{Q}(G, T^G)$ is the set of closed $\mathbb{C}$-subgroups $Q$ of $T^G$ such that $Q = T^G \cap C_G(Q)$, where $C_G(Q) = \{g \in G : sg = gs, s \in Q\}$ and $i_Q : [X/Q] \to \mathcal{M} \cong [X/G]$ is the natural projection 1-morphism. Similarly, one defines $\text{SF}([\mathcal{M}, \chi, \mathbb{Q}])$ by restricting the 1-morphisms $\rho$ in parts (a)–(c) to be representable.

(d) There exist the notions of multiplication, pullback, pushforward of stack functions in $\text{SF}([\mathcal{M}, \chi, \mathbb{Q}])$ and $\text{SF}([\mathcal{M}, \chi, \mathbb{Q}])$. For further discussions look at [10, Definitions 2.6, 2.7 and Theorem 2.9].

Joyce and Song in [10, Section 13.3] define the notion of characteristic stack functions $\delta_\mathcal{M}^{(\beta, d)}(\bar{\tau}) \in \text{SF}([\mathcal{M}, \beta, \mathbb{Q}) \times \mathcal{C}(\mathbb{B}_p))$. Now define elements $\tau^{(\beta, r)}(\bar{\tau})$ in $\text{SF}_\mathcal{M}([\mathcal{M}, \beta, \mathbb{Q}) \times \mathcal{C}(\mathbb{B}_p))$ where $*$ is the Ringel–Hall multiplication defined in [10, Definition 3.3].

**Definition 13** Define the stack functions

$$\tau^{(\beta, r)}(\bar{\tau}) = \sum_{(\beta_1, r_1), \ldots, (\beta_n, r_n) \in \mathcal{C}(\mathbb{B}_p)} \frac{(-1)^{n-1}}{n} \delta^{(\beta_1, r_1)}(\bar{\tau}) * \delta^{(\beta_2, r_2)}(\bar{\tau}) * \cdots * \delta^{(\beta_n, r_n)}(\bar{\tau}),$$

(4)

where $*$ is the Ringel–Hall multiplication defined in [10, Definition 3.3].

Our goal in the remainder of this article is to first evaluate the element of the Hall algebra $\tau^{(\beta, r)}(\bar{\tau})$ above, by explicitly computing the right-hand side of (4), and then calculate the invariants. To do this one needs to apply the Joyce–Song Lie algebra morphism to $\tau^{(\beta, r)}(\bar{\tau})$. In order to clarify the latter, we need further definitions.

**Definition 14** ([10, Definition 13.3]) Define the Euler form in $\mathbb{B}_p$ as $\mathcal{F}_{\mathbb{B}_p} : K(\mathbb{B}_p) \times K(\mathbb{B}_p) \to \mathbb{Z}$ such that

$$\mathcal{F}_{\mathbb{B}_p}(\beta, d, (\gamma, e)) = \mathcal{F}(\beta, \gamma) - d \mathcal{F}([\mathcal{O}_X(-n)], \gamma) + e \mathcal{F}([\mathcal{O}_X(-n)], \beta).$$
where \( \overline{\tau}(\cdot) \) is the Euler form on \( K(\text{Coh}(X)) \).

**Definition 15** ([10, Definition 13.11]) Define \( S \) to be the subset of \( (\beta, d) \) in \( \mathfrak{c}(\mathcal{B}_p) \subset K(\mathcal{B}_p) \) such that \( P_p(t) = k_p(t) / d! \) for \( k = 0, \ldots, N \) and \( d = 0 \) or \( 1 \) or \( 2 \). Then \( S \) is a finite set [7, Theorem 3.37]. Define the Lie algebra \( \mathcal{L}(\mathcal{B}_p) \) to be the \( \mathbb{Q} \)-vector space with the basis of symbols \( \overline{\tau}(\beta, d) \) with \( (\beta, d) \in S \) with the Lie bracket

\[
\lbrack \overline{\tau}(\beta, d), \overline{\tau}(\gamma, e) \rbrack = (\overline{\tau}(\beta + \gamma, d + e) - \overline{\tau}(\beta, d) - \overline{\tau}(\gamma, e))
\]

for \( (\beta + \gamma, d + e) \in S \) and \( \lbrack \overline{\tau}(\beta, d), \overline{\tau}(\gamma, e) \rbrack = 0 \) otherwise. Here it can be seen that \( \mathcal{L}(\mathcal{B}_p) \) is antisymmetric and hence equation (5) satisfies the Jacobi-identity and that makes \( \mathcal{L}(\mathcal{B}_p) \) into a finite-dimensional nilpotent Lie algebra over \( \mathbb{Q} \).

Now the *Joyce–Song Lie algebra morphism* is defined as the \( \mathbb{Q} \)-linear map \( \overline{\Psi}^p: \mathfrak{F}_d^\text{ind} \mathcal{M}_{\mathcal{B}_p} \to \mathcal{L}(\mathcal{B}_p) \) by applying [10, Definition 5.13] to the moduli stack \( \mathcal{M}_{\mathcal{B}_p} \) and \( \mathcal{L}(\mathcal{B}_p) \).

**Definition 16** Define the invariant \( \mathfrak{B}^\omega_p(X, \beta, r, \bar{\tau}) \) associated to \( \bar{\tau} \)-semistable objects of type \( (\beta, r) \) in \( \mathcal{B}_p \) by

\[
\overline{\Psi}^p (\mathfrak{B}(\beta, r, \bar{\tau})) = \mathfrak{B}^\omega_p(X, \beta, r, \bar{\tau}) \cdot \overline{\tau}(\beta, r)
\]

where \( \overline{\Psi}^p \) is given by the Lie algebra morphism above.

From now on, to minimize the unnecessary computational complexity, we restrict our analysis to rank 2 pairs, i.e. \( r = 2 \). First to motivate the intuition behind our computations we study an interesting example.

### 3 Direct computation of invariants in an example

**Example 1** Computation of \( \mathfrak{B}^\omega_p(X, [\mathbb{P}^1], 2, \bar{\tau}) \), where \( X \) is given by the total space of \( \mathcal{O}^\otimes_{\mathbb{P}^1}(-1) \to \mathbb{P}^1 \).

We compute the invariant of \( \bar{\tau} \)-semistable objects \( (F, \mathcal{C}^2, \phi_{\mathcal{C}^2}) \) of type \([\mathbb{P}^1], 2\) in \( \mathcal{B}_p \). In this case \( F \) has rank 1 over its support and \( p_F(n) = n + \chi(F) \). Assume that \( \chi(F) = k \). In this case by computations in [5, 11] the only semistable sheaf \( F \) with \( \chi_2(F) = [\mathbb{P}^1] \) is given by \( \mathcal{O}_{\mathbb{P}^1}(k - 1) \) which is a stable sheaf. First we give the description of \( \mathfrak{M}_{\mathcal{B}_p, \text{ss}}([\mathbb{P}^1], \bar{\tau}) \).

By definition, an object of type \([\mathbb{P}^1], 2\) in \( \mathcal{B}_p \) is identified by a complex \( \mathcal{O}_X(-n)^{\otimes 2} \to \iota_* \mathcal{O}_{\mathbb{P}^1}(k - 1) \), where \( \iota: \mathbb{P}^1 \to X \) (from now on we suppress \( \iota_* \) in our notation). By the constructions in Sect. 1.2, the parameter scheme of \( \bar{\tau} \)-semistable objects is

\[ \text{For further detail look at [10, Definition 13.11].} \]
obtained by choosing two sections \((s_1, s_2)\) such that \(s_i \in \mathcal{H}^0(\mathcal{O}_{\mathbb{P}^1}(n+k-1))\) for \(i = 1, 2\). Moreover since \(\mathcal{O}_{\mathbb{P}^1}(k-1)\) is a stable sheaf, its stabilizer is given by \(\mathbb{G}_m\).

An important point to note is that, given a \(\tilde{\tau}\)-semistable object \((F, \mathbb{C}^2, \phi_{\mathbb{C}^2})\), one is always able to obtain an exact sequence of the form

\[
0 \to (F, C, \phi_C) \to (F, \mathbb{C}^2, \phi_{\mathbb{C}^2}) \to (0, C, 0) \to 0,
\]

for every object in the moduli stack and since \(\tilde{\tau}(F, \mathbb{C}^2, \phi_{\mathbb{C}^2}) = 1 \leq \tilde{\tau}(0, C, 0) = 1\), one concludes that all objects parametrized by the moduli stack are given by extensions of rank 1 \(\tilde{\tau}\)-stable objects and hence all objects are \(\tilde{\tau}\)-strictly-semistable. Moreover, note that giving a \(\tilde{\tau}\)-semistable object of the form

\[
\mathcal{O}_X(-n)^{\oplus 2} \xrightarrow{(s_1, s_2)} F
\]

is equivalent to requiring the condition that \((s_1, s_2) \neq (0, 0)\), since otherwise, one may be able to obtain an exact sequence

\[
0 \to (\mathbb{C}^2, 0, 0) \to (\mathbb{C}^2, F, 0) \to (0, F, 0) \to 0
\]

such that \(\tilde{\tau}(\mathbb{C}^2, 0, 0) = 1 > \tilde{\tau}(0, F, 0) = 0\), hence \((\mathbb{C}^2, 0, 0)\) (weakly) destabilizes \((\mathbb{C}^2, F, 0)\), hence a contradiction. Now use Theorem 1 and find that

\[
\mathfrak{M}_{b_p, ss}^{[\mathbb{P}^1, 2]}(\tilde{\tau}) = \left[ \frac{\mathcal{H}^0(\mathcal{O}_{\mathbb{P}^1}(n+k-1))^{\oplus 2} \setminus \{0\}/\mathbb{G}_m}{\text{GL}_2(\mathbb{C})} \right] \cong \left[ \mathbb{P}(\mathcal{H}^0(\mathcal{O}_{\mathbb{P}^1}(n+k-1))^{\oplus 2}) / \text{GL}_2(\mathbb{C}) \right].
\]

We need to compute the element of the Hall algebra \(\tau^{[\mathbb{P}^1, 2]}(\tilde{\tau})\). By applying Definition 13 to \(\mathfrak{M}_{b_p, ss}^{[\mathbb{P}^1, 2]}(\tilde{\tau})\), we obtain

\[
\tau^{[\mathbb{P}^1, 2]}(\tilde{\tau}) = \tau_{ss}^{[\mathbb{P}^1, 2]}(\tilde{\tau}) - \frac{1}{2} \sum_{\beta_k + \beta_i = [\mathbb{P}^1]} \delta_{\tilde{\beta}_k, \tilde{\beta}_i}(\tilde{\tau}) \ast \delta_{1, \tilde{\beta}_i}(\tilde{\tau}).
\]

Now we use a stratification strategy in order to decompose \(\mathfrak{M}_{b_p, ss}^{[\mathbb{P}^1, 2]}(\tilde{\tau})\) into a disjoint union of strata as follows. Since the objects in the moduli stack are of type \(([\mathbb{P}^1], 2)\), one would immediately see that the only possible decomposition of a \(\tilde{\tau}\)-semistable object of type \(([\mathbb{P}^1], 2)\) is given by \(([\mathbb{P}^1], 2) = ([\mathbb{P}^1], 1) + (0, 1)\). This means that a strictly \(\tilde{\tau}\)-semistable object of type \(([\mathbb{P}^1], 2)\) is always given by an (split or non-split) extension, involving an object of type \(([\mathbb{P}^1], 1)\) and an object of type \((0, 1)\). Note that it is allowable to flip the order of an extension, as long as the original strictly semistable object is re-produced. Our stratification then involves a study of the parametrizing moduli stack for the objects, depending on which extension is used to produce them. This will enable us to decompose \(\mathfrak{M}_{b_p, ss}^{[\mathbb{P}^1, 2]}(\tilde{\tau})\) into a disjoint union of split and non-split strata (i.e. induced by split or non-split extensions).
Definition 17 Define $\mathcal{M}(\mathbb{P}^1, 2)_{\text{sp}}(\bar{\tau}) \subset \mathcal{M}(\mathbb{P}^1, 2)_{\text{ss}}(\bar{\tau})$ to be the locally closed stratum over which an object of type $(\mathbb{P}^1, 2)$ is given by split extensions involving objects of type $(\mathbb{P}^1, 1)$ and $(0, 1)$. Define $\mathcal{M}(\mathbb{P}^1, 2)_{\text{ss}}(\bar{\tau}) \subset \mathcal{M}(\mathbb{P}^1, 2)_{\text{sp}}(\bar{\tau})$ to be the locally closed stratum over which an object of type $(\mathbb{P}^1, 2)$ is given by non-split extensions involving objects of type $(\mathbb{P}^1, 1)$ and $(0, 1)$.

Now we study the structure of each stratum separately.

3.1 Stacky structure of $\mathcal{M}(\mathbb{P}^1, 2)_{\text{sp}}(\bar{\tau})$

It is easy to see that any $\mathcal{O}_X(\mathbb{P}^1, 2)$-semistable objects of type $(\mathbb{P}^1, 2)$ given as

$$[\mathcal{O}_X(-n)^{\oplus 2} \to \mathcal{O}_{\mathbb{P}^1}(k-1) \cong [\mathcal{O}_X(-n)^{\oplus 2} \to \mathcal{O}_{\mathbb{P}^1}(k-1)] \oplus [\mathcal{O}_X(-n) \to 0]$$

has the property that the sections $s_1, s_2$ for this object are linearly dependent on one another. Hence the underlying parameter scheme of $\mathcal{O}_X$-semistable objects of this given form is given by choosing a nonzero section of $\mathcal{O}_{\mathbb{P}^1}(n+k-1)$, in other words we obtain $H^0(\mathcal{O}_{\mathbb{P}^1}(n+k-1)) \setminus \{0\}$. Now we need to take the quotient of this space by the stabilizer group of points. We know that the condition required for a $\mathcal{O}_X$-semistable object

$$\mathcal{O}_X(-n)^{\oplus 2} \xrightarrow{(s_1,s_2)} F$$

to be given by split extensions of rank 1 objects is that $s_1$ and $s_2$ are linearly dependent on one another. Now pick such an object given by

$$\mathcal{O}_X(-n)^{\oplus 2} \xrightarrow{(s_1,0)} F.$$ 

The automorphisms of this object are given by the group which makes the following diagram commutative:

$$\begin{array}{ccc}
\mathcal{O}_X(-n)^{\oplus 2} & \xrightarrow{(s_1,0)} & \mathcal{O}_{\mathbb{P}^1}(k-1) \\
\cong & & \cong \\
\mathcal{O}_X(-n)^{\oplus 2} & \xrightarrow{(s_1,0)} & \mathcal{O}_{\mathbb{P}^1}(k-1).
\end{array}$$

Hence it is seen that the left vertical map needs to be given by a subgroup of $\text{GL}_2(\mathbb{C})$ which preserves $s_1$, i.e. the Borel subgroup of $\text{GL}_2(\mathbb{C})$ whose elements are given by $2 \times 2$ upper triangular matrices

$$\begin{pmatrix} k_1 & k_2 \\ 0 & k_3 \end{pmatrix},$$

where $k_1, k_3 \in \mathbb{G}_m$ and $k_2 \in \mathbb{A}^1$. Having fixed one of the automorphisms via fixing $k_1, k_2, k_3$, it is seen that, by the commutativity of the square diagram, the right vertical map needs to be given by multiplication by $k_1$ which is an element of $\mathbb{G}_m$. Note that one needs to take the quotient of the parameter scheme by all isomorphisms between any two objects in the split stratum, not just the automorphisms of one fixed representative. In general for an
object to live in the split stratum one requires the sections \((s_1, s_2)\) to be given by \((s_1, a \cdot s_1)\). We observed that fixing a representative for a split object of rank 2 (such as fixing \((s_1, s_2) = (s_1, 0)\) as above) would tell us that its automorphisms are given by \(\mathbb{G}_m^2 \rtimes \mathbb{A}^1\). Hence, taking into account all possible representatives implies that the stabilizer group of objects in the split stratum is given by \(\mathbb{G}_m^2 \rtimes \mathbb{A}^1/\text{ST}_X\mathbb{G}_m\). Hence we obtain

\[
\mathfrak{M}^{[\mathbb{P}^1, 2]}(\bar{\tau}) = \left[ \frac{H^0(\mathcal{O}_{\mathbb{P}^1 (n + k - 1)}) \setminus \{0\}}{\mathbb{G}_m^2 \rtimes \mathbb{A}^1} \right] = \left[ \frac{\mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^1 (n + k - 1)}))}{\mathbb{G}_m^2 \rtimes \mathbb{A}^1} \right].
\] (9)

### 3.2 Stacky structure of \(\mathfrak{M}^{[\mathbb{P}^1, 2]}(\bar{\tau})\)

In this case, the objects in \(\mathfrak{M}^{[\mathbb{P}^1, 2]}(\bar{\tau})\) are given by non-split extensions of the form

\[
\begin{array}{cccccccc}
0 & \to & \mathcal{O}_X(-n) & \to & \mathcal{O}_X^{\mathbb{P}^1, 2}(-n) & \to & \mathcal{O}_X(-n) & \to & 0 \\
0 & \to & \mathcal{O}_{\mathbb{P}^1}(k - 1) & \xrightarrow{(s_1, s_2)} & F & \to & 0 & \to & 0.
\end{array}
\] (10)

Note that switching the place of \(\mathcal{O}_{\mathbb{P}^1}(k - 1)\) and 0 in the bottom row of diagram (10) would produce a split extension and so such extensions cannot lie in the non-split stratum. Now, in order to obtain non-split extensions, one needs to choose two sections \(s_1, s_2\) such that \(s_1 \) and \(s_2\) are linearly independent. The set of all linearly independent choices of \(s_1\) and \(s_2\) spans a two dimensional subspace of \(H^0(\mathcal{O}_{\mathbb{P}^1 (n + k - 1)})\) which is given by the Grassmanian \(G(2, n + k)\).

Now, we need to take the quotient of this scheme by the stabilizer group of points in the stratum. We know that the condition required for a \(\bar{\tau}\)-semistable object

\[
\mathcal{O}_X(-n)^{\mathbb{P}^1, 2} \xrightarrow{(s_1, s_2)} F
\]

to be given by non-split extensions of rank 1 objects is that \(s_1\) and \(s_2\) are linearly independent. Now pick such an object given by

\[
\mathcal{O}_X(-n)^{\mathbb{P}^1, 2} \xrightarrow{(s_1, s_2)} F.
\]

The automorphisms of this object are given by the group which makes the following diagram commutative:

\[
\begin{array}{cccccccc}
\mathcal{O}_X(-n)^{\mathbb{P}^1, 2} & \xrightarrow{(s_1, s_2)} & \mathcal{O}_{\mathbb{P}^1}(k - 1) \\
\xrightarrow{=} & & \xrightarrow{=} \\
\mathcal{O}_X(-n)^{\mathbb{P}^1, 2} & \xrightarrow{(s_1, s_2)} & \mathcal{O}_{\mathbb{P}^1}(k - 1).
\end{array}
\]
Hence it is seen that the left vertical map needs to be given by a subgroup of $GL_2(\mathbb{C})$ whose elements are given by $2 \times 2$ diagonal matrices of the form \[
abla = \begin{pmatrix} k_1 & 0 \\ 0 & k_2 \end{pmatrix}, \] where $k_1 \in \mathbb{G}_m$. Having fixed one of the automorphisms via fixing $k_1$, it is seen that by the commutativity of the square diagram, the right vertical map needs to be given by multiplication by $k_1$ which is an element of $\mathbb{G}_m$. Hence we obtain

\[
\mathfrak{M}_{[p^1,2]}(\bar{r}) = \left[ \frac{G(2, n + k)}{\mathbb{G}_m} \right].
\] (11)

Now we are ready to compute $\sum_{\beta_2 + \beta_1 = [p^1]} \overline{\delta}_s^{(\beta_2 + \beta_1)}(\bar{r}) * \overline{\delta}_s^{(\beta_1)}(\bar{r})$ appearing on the right-hand side of (8). We use the fact that

\[
\sum_{\beta_2 + \beta_1 = [p^1]} \overline{\delta}_s^{(\beta_2 + \beta_1)}(\bar{r}) * \overline{\delta}_s^{(\beta_1)}(\bar{r}) = \overline{\delta}_s^{([p^1],1)}(\bar{r}) * \overline{\delta}_s^{([0,1])}(\bar{r}) + \overline{\delta}_s^{([0,1])}(\bar{r}) * \overline{\delta}_s^{([p^1],1)}(\bar{r})
\] (12)

and compute each term on the right-hand side of (12) separately.

Remark 3 As we described above, there exists an action of $GL_2(\mathbb{C})$ on

\[
S = \mathbb{P}(H^0(\mathcal{O}_{p^1}(n + k - 1))^{\oplus 2}).
\]

This action induces an action of the corresponding Lie algebra on the tangent space of $S$ given by the map

\[
\mathcal{O}_S \otimes \mathfrak{gl}_2(\mathbb{C}) \rightarrow T_S,
\] (13)

where $\mathfrak{gl}_2(\mathbb{C})$ denotes the Lie algebra associated to the group $GL_2(\mathbb{C})$. The dimension of the automorphism group of objects representing the elements of $S$ is given by the dimension of the stabilizer (in $GL_2(\mathbb{C})$) group of these elements, which itself is given by the dimension of the kernel of the map in (13). On the other hand, the dimension of the kernel of the map in (13) is an upper-semicontinuous function. Therefore by the usual arguments, we obtain a stratification of $S$ which induces a stratification of

\[
\left[ \frac{S}{GL_2(\mathbb{C})} \right]
\]

into locally closed strata, such that over each stratum the dimension of the stabilizer group is constant as we vary over points inside that stratum. Here in Definition 17 we stated without proof that the defined strata are locally closed in $\mathfrak{M}_{[p^1,2]}(\bar{r})$, this is discussed in detail and for more general cases in Appendix 10.
3.3 Computation of $\overline{\delta}_s^{(p^1,1)}(\overline{\tau}) \ast \overline{\delta}_s^{(0,1)}(\overline{\tau})$

Given

$$\overline{\delta}_s^{(p^1,1)}(\overline{\tau}) = \left( \left[ \frac{\mathcal{P}(\mathbb{H}^0(\mathcal{O}_2(n+k-1)))}{G_m} \right], \rho_1 \right),$$

$$\overline{\delta}_s^{(0,1)}(\overline{\tau}) = \left( \left[ \text{Spec}(\mathbb{C}) \right], \rho_2 \right)$$

($\rho_1, \rho_2$ are natural embedding maps to $\mathcal{M}_{\beta,p}(\overline{\tau})$), consider the diagram

$$\xymatrix{ Z_{12}' \ar[r]^\Phi \ar[d] & \text{Fact}_{\beta,p} \ar[d]^{\pi_1 \times \pi_3} \\ \left[ \frac{\mathcal{P}(\mathbb{H}^0(\mathcal{O}_2(n+k-1)))}{G_m} \right] \times \left[ \text{Spec}(\mathbb{C}) \right] & \mathcal{M}_{\beta,p}(\overline{\tau}) \times \mathcal{M}_{\beta,p}(\overline{\tau}),}$

where $Z_{12}'$ is given by the scheme parametrizing the set of commutative diagrams

$$\xymatrix{ 0 \ar[r] & \mathcal{O}_X(-n) \ar[r]^{s_1} & \mathcal{O}_X^{\otimes 2}(-n) \ar[r] & \mathcal{O}_X(-n) \ar[r] & 0 \\ 0 \ar[r] & \mathcal{O}_{\mathcal{P}^1}(k-1) \ar[r]^{s_2} & \mathcal{O}_{\mathcal{P}^1}(k-1) \ar[r] & \mathcal{O}_{\mathcal{P}^1}(k-1) \ar[r] & 0.}

(14)

Since that the extensions in (14) have the possibility of being split or non-split, therefore, we consider each case separately and define the multiplication

$$\overline{\delta}_s^{(p^1,1)}(\overline{\tau}) \ast \overline{\delta}_s^{(0,1)}(\overline{\tau})$$

in each case separately as follows below.

**Definition 18** Let $[\overline{\delta}_s^{(p^1,1)}(\overline{\tau}) \ast \overline{\delta}_s^{(0,1)}(\overline{\tau})]_{sp}$ denote the stratum of $(\pi_2 \circ \Phi)_* Z_{12}'$ over which the points are represented by split extensions given by the commutative diagram in (14).

**Definition 19** Let $[\overline{\delta}_s^{(p^1,1)}(\overline{\tau}) \ast \overline{\delta}_s^{(0,1)}(\overline{\tau})]_{nsp}$ denote the stratum of $(\pi_2 \circ \Phi)_* Z_{12}'$ over which the points are represented by the non-split extensions given by commutative diagram in (14).

Therefore

$$\overline{\delta}_s^{(p^1,1)}(\overline{\tau}) \ast \overline{\delta}_s^{(0,1)}(\overline{\tau}) = [\overline{\delta}_s^{(p^1,1)}(\overline{\tau}) \ast \overline{\delta}_s^{(0,1)}(\overline{\tau})]_{sp} + [\overline{\delta}_s^{(p^1,1)}(\overline{\tau}) \ast \overline{\delta}_s^{(0,1)}(\overline{\tau})]_{nsp}.$$

Now we compute $[\overline{\delta}_s^{(p^1,1)}(\overline{\tau}) \ast \overline{\delta}_s^{(0,1)}(\overline{\tau})]_{sp}$. This amounts to choosing $s_1, s_2$ so that $s_1$ and $s_2$ are linearly depending on one another. The scheme parametrizing nonzero
sections \( s_1 \) is given by \( \mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^1}(n+k-1))) \). Now we take the quotient of this scheme by the stabilizer group of points. Similar to arguments in [16, Lemma 12.1], given any point in \( \mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^1}(n+k-1))) \) represented by the extension in (14), its stabilizer group is given by the semi-direct product \( \mathbb{G}_m \rtimes \text{Hom}(E_3, E_1) \), where each factor of \( \mathbb{G}_m \) amounts to the stabilizer group of objects given as \( E_3 = \mathcal{O}_X(-n) \rightarrow 0 \) and \( E_1 = \mathcal{O}_X(-n) \rightarrow \mathcal{O}_{\mathbb{P}^1}(k-1) \) respectively. Note that the extra factor of \( \mathbb{A}^1 \) will not appear as a part of the stabilizer group since, by the given description of \( E_1 \) and \( E_3 \), we know that \( \text{Hom}(E_3, E_1) = 0 \) for every such \( E_1 \) and \( E_3 \). We obtain the following conclusion:

\[
\left[ \bar{\delta}_s^{(p^1,1)}(\tilde{\tau}) \ast \tilde{\sigma}_s^{(0,1)}(\tilde{\tau}) \right]_{\text{sp}} = \left[ \frac{\mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^1}(n+k-1))))}{\mathbb{G}_m^2} \right].
\]

(15)

Now we compute \( \left[ \bar{\eta}_s^{(p^1,1)}(\tilde{\tau}) \ast \tilde{\sigma}_s^{(0,1)}(\tilde{\tau}) \right]_{\text{sp}} \). This amounts to choosing \( s_1, s_2 \) so that \( s_1 \) and \( s_2 \) are linearly independent and the extension in diagram (14) becomes non-split. Note that for any fixed value of \( s_1 \), one has \( \mathbb{P}^1 \) worth of choices for \( s_2 \). Now we need to consider all possible choices of \( s_1 \) and in doing so, we require the sections \( s_1, s_2 \) to remain linearly independent. This gives the flag variety \( F(1, 2, n+k) \). Hence we obtain

\[
\left[ \bar{\eta}_s^{(p^1,1)}(\tilde{\tau}) \ast \tilde{\sigma}_s^{(0,1)}(\tilde{\tau}) \right]_{\text{sp}} = \left[ \frac{\mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^1}(n+k-1))))}{\mathbb{G}_m^2} \right] + \left[ \frac{\mathbb{F}(1, 2, n+k)}{\mathbb{G}_m} \right].
\]

(16)

Note that the factor of \( \mathbb{G}_m \) in the denominator of (16) is due to the fact that we have used one of the \( \mathbb{G}_m \) factors in projectivising the bundle of \( s_2 \)-choices over the Grassmanian. We finish this section by summarizing our computation. By (15) and (16) one obtains

\[
\bar{\eta}_s^{(p^1,1)}(\tilde{\tau}) \ast \tilde{\sigma}_s^{(0,1)}(\tilde{\tau}) = \left[ \frac{\mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^1}(n+k-1))))}{\mathbb{G}_m^2} \right] + \left[ \frac{\mathbb{F}(1, 2, n+k)}{\mathbb{G}_m} \right].
\]

(17)

3.4 Computation of \( \bar{\eta}_s^{(0,1)}(\tilde{\tau}) \ast \tilde{\sigma}_s^{(p^1,1)}(\tilde{\tau}) \)

Now change the order of \( \bar{\eta}_s^{(0,1)}(\tilde{\tau}) \) and \( \tilde{\sigma}_s^{(p^1,1)}(\tilde{\tau}) \) and obtain the diagram

\[
\begin{array}{c}
\mathbb{Spec}(\mathbb{C}) \\
\mathbb{G}_m \end{array} \xrightarrow{\varrho_2 \times \varrho_1} \mathbb{P}(H^0(\mathcal{O}_{\mathbb{P}^1}(n+k-1))) \xrightarrow{\rho_2 \times \rho_1} \mathfrak{M}_{\mathbb{P}^1}(\tilde{\tau}) \times \mathfrak{M}_{\mathbb{P}^1}(\tilde{\tau}).
\]

Here \( \mathbb{Z}'_{\mathcal{A}^1} \) is given by the scheme parametrizing the set of commutative diagrams

\[
\begin{array}{cccccc}
0 & \longrightarrow & \mathcal{O}_X(-n) & \longrightarrow & \mathcal{O}_X^2(-n) & \longrightarrow & \mathcal{O}_X(-n) & \longrightarrow & 0 \\
0 & \downarrow & \varnothing & \downarrow & (0,s_2) & \downarrow & \varnothing & \downarrow & 0 \\
0 & \longrightarrow & 0 & \longrightarrow & F & \longrightarrow & \mathcal{O}_{\mathbb{P}^1}(k-1) & \longrightarrow & 0.
\end{array}
\]

(18)
Note that the computation in this case is easier since the only possible extensions of the form given in (18) are the split extensions. The computation in this case is similar to computation in (15) except that one needs to take into account that over any point represented by an extension (as in diagram (18)) of $E_1 = \mathcal{O}_X(-n) \to 0$ and $E_3 = \mathcal{O}_X(-n) \to \mathcal{O}_{P^1}(k - 1)$ we have $\text{Hom}(E_3, E_1) \cong \mathbb{A}^1$. Hence by similar discussions we obtain

$$\mathbb{F}_s^\bullet([P^1, 1])(\tilde{\epsilon}) * \mathbb{F}_s^\bullet([0, 1])(\tilde{\epsilon}) = \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2 \times \mathbb{A}^1} \right].$$

(19)

3.5 Computation of $\tau^{(\beta, 2)}(\tilde{\epsilon})$

By (8), (9), (11), (12), (17) and (19) we obtain

$$\tau^{(\beta, 2)}(\tilde{\epsilon}) = \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2 \times \mathbb{A}^1} \right] + \left[ \frac{G(2, n + k)}{G_m^2} \right]$$

$$- \frac{1}{2} \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2} \right]$$

$$- \frac{1}{2} \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2} \right]$$

$$+ \frac{1}{2} \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2} \right].$$

(20)

Now use the decomposition used by Joyce and Song in [10, p. 158] and write

$$\left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2 \times \mathbb{A}^1} \right] = F(G, G_m^2, G_m^2) \cdot \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2} \right]$$

$$+ F(G, G_m^2, G_m) \cdot \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m} \right].$$

where $F(G, G_m^2, G_m^2) = 1$ and $F(G, G_m^2, G_m) = -1$. Equation (20) simplifies as follows:

$$\tau^{(\beta, 2)}(\tilde{\epsilon}) = \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2} \right] - \frac{1}{2} \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2} \right]$$

$$+ \frac{1}{2} \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2} \right]$$

$$- \frac{1}{2} \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2} \right]$$

$$- \frac{1}{2} \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2} \right]$$

$$+ \frac{1}{2} \left[ \frac{\mathbb{P}(\mathcal{H}^0(\mathcal{O}_{P^1}(n + k - 1)))}{G_m^2} \right].$$
Now use Definition 22 and write
\[
\left[ \frac{G(2, n+k)}{\mathbb{G}_m} \right] = \chi(G(2, n+k)) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right]
\]
and
\[
\left[ \frac{F(1, 2, n+k)}{\mathbb{G}_m} \right] = \chi(F(1, 2, n+k)) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right]
= \chi(\mathbb{P}^1) \cdot \chi(G(2, n+k)) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right]
= 2 \cdot \chi(G(2, n+k)) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right]
\]
(21)

where the second equality is due to the fact that the topological Euler characteristic of a vector bundle over a base variety is equal to the Euler characteristic of its fibers times the Euler characteristic of the base. By (20) and (21), we obtain
\[
-\frac{1}{2} \left[ \frac{\mathbb{P}(\mathcal{O}_{\mathbb{P}^1}(n+k-1))}{\mathbb{G}_m} \right] + \chi(G(2, n+k)) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right] - 2 \cdot \frac{1}{2} \cdot \chi(G(2, n+k)) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right]
= -\frac{1}{2} \left[ \frac{\mathbb{P}(\mathcal{O}_{\mathbb{P}^1}(n+k-1))}{\mathbb{G}_m} \right]
= -\frac{1}{2} \chi(\mathbb{P}(\mathcal{O}_{\mathbb{P}^1}(n+k-1))) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right]
= -\frac{1}{2} \chi(\mathbb{P}(\mathcal{O}_{\mathbb{P}^1}(n+k-1))) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right]
\]

3.6 Computation of the invariant

Now apply the Lie algebra morphism $\Psi^{2,2}$ in Definition 15 to $\tau([\mathbb{P}^1], 2)(\overline{\tau})$. By definition,
\[
\Psi^{2,2}(\tau([\mathbb{P}^1], 2)(\overline{\tau})) = \chi^\text{naive} \left( -\frac{1}{2} \left( n+k \right) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right] \cdot (\mu \circ i_2)^* \nu_{\Psi^{2,2}} \right) \cdot \overline{\tau},
\]
where by $\chi^\text{naive}$ we mean the naive Euler characteristic defined by Joyce and Song [10, Definition 2.3], weighted by the corresponding Behrend function. Note that by (7),
\[
\nu^{\mathbb{P}^1, 2}\left( \overline{\tau} \right) = \left[ \frac{\mathbb{P}(\mathcal{O}_{\mathbb{P}^1}(n+k-1))}{\mathbb{G}_m} \right] \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right]
\]
and hence
\[
\chi(\mathbb{P}(\mathcal{O}_{\mathbb{P}^1}(n+k-1))) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right]
\]
has relative dimension $-1 - (2n + 2k - 5) = 4 - 2n - 2k$ over $\mathcal{M}_{[\mathbb{P}^1],,2}^p(\tilde{\tau})$. Moreover,

$$\left[ \frac{\text{Spec}(\mathbb{C})}{G_m} \right]$$

is given by a single point with Behrend’s multiplicity $-1$ and

$$(\mu \circ i)^* v_{\mathcal{M}_{[\mathbb{P}^1],,2}^p} \cdot \lambda((\mathbb{P}^1),,2) = (-1)^{4-2n-2k} \cdot v_{\frac{\text{Spec}(\mathbb{C})}{G_m}} = v_{\frac{\text{Spec}(\mathbb{C})}{G_m}},$$

therefore,

$$\tilde{\nu}^p_{[\mathbb{P}^1],,2}(\tilde{\tau}) = \chi^m \left( -\frac{1}{2} (n + k) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{G_m} \right], v_{\frac{\text{Spec}(\mathbb{C})}{G_m}} \right) \cdot \lambda((\mathbb{P}^1),,2)$$

$$= (-1)^1 \cdot \left( -\frac{1}{2} (n + k) \right) \lambda((\mathbb{P}^1),,2).$$

Finally by Definition 16, we obtain

$$B_p^\alpha(X, \beta, 2, \tilde{\tau}) = \frac{n + k}{2}. \quad (22)$$

Note that a simple calculation shows that substituting $([\mathbb{P}^1], 2)$ for $(\beta, 2)$ in [16, Equation (5.2)] would give the same answer as in (22). Hence our result is compatible with wallcrossing calculations.

To summarize, in Sect. 3 we introduced our strategy of direct computations over an example where $r = 2$ and $\beta$ was given by the irreducible class $[\mathbb{P}^1]$. Our strategy involved computing the weighted Euler characteristic of the right-hand side of (8). After carefully analyzing the stacky structure of the moduli space of objects of type $([\mathbb{P}^1], 2)$ (Sect. 3.2), first we computed the second summand on the right-hand side of (8) (Sects. 3.3 and 3.4). Then, by the stratification of the original moduli stack, we showed that the first summand on the right-hand side of (8) is written as a sum of the characteristic stack functions of the strata in a suitable way, such that essentially the difference of the first and second summands on the right-hand side of (8) turned out to be given as a sum of stack functions supported over virtual indecomposables. This enabled us to apply the Lie algebra morphism defined in Definition 15 to both sides of (8) and obtain the final answer in (22).

4 Direct calculations in general cases

In this section we extend the computational strategy in Sect. 3 to one level of generalization further, i.e. to the case where $r = 2$, however $\beta$ can have the possibility of being given by a reducible class. Eventually the final generalization, which is to consider semistable pairs with rank $> 2$, follows the same strategy as will be described in detail below.
As was seen above, a key condition to hold for our strategy to work is that the strata involved in our stratification are locally closed and disjoint from one another. In order to show that such stratification is possible for general cases, we start below by assuming that an object $E_2: \mathcal{O}_X(-n) \rightarrow F_2$, with $F_2$ being a semistable sheaf with reducible Chern character, is decomposable into rank 1 objects $E_1 = \mathcal{O}_X(-n) \rightarrow F_1$ and $E_3 = \mathcal{O}_X(-n) \rightarrow F_3$, where $F_1, F_3$ are stable sheaves. We then show that the moduli space parameterizing $E_2$ can be decomposed into a disjoint union of locally closed strata, depending on how $E_2$ is produced by extensions of $E_1, E_3$. In other words, we will show below that the extensions of the form $0 \rightarrow E_1 \rightarrow E_2 \rightarrow E_3 \rightarrow 0$ (depending on being split or non-split), or the ones with the order of the extension flipped as in $0 \rightarrow E_3 \rightarrow E_2 \rightarrow E_1 \rightarrow 0$ are all locally closed and disjoint from one another.

Assumption 1 Throughout this section we assume that a $\tau$-semistable object $(F, V, \phi_V) \in B_p$ of type $(\beta, 2)$ has the property that $\beta$ is either indecomposable or it satisfies the condition that if $\beta = \beta_k + \beta_l$ (i.e. if $\beta$ is decomposable) then $\beta_k = [F_k]$ and $\beta_l = [F_l]$ such that $F_k$ and $F_l$ are $\tau$-stable sheaves with fixed reduced Hilbert polynomial $p$. In other words, $\beta$ cannot be decomposed into smaller classes whose associated sheaves are not $\tau$-stable.

Lemma 2 Let $\mathcal{S}_x^{(\beta_k, 1)}$ and $\mathcal{S}_x^{(\beta_l, 1)}$ (for some $\beta_k, \beta_l$) denote the underlying schemes, as in Sect. 1.2 given as a bundle $\mathcal{P}$ over the $\tau$-stable locus of the Quot-scheme $Q^3 \subset Q$, parameterizing maps $\mathcal{O}_X(-n) \rightarrow F$ such that the Chern character of $F$ is given by $\beta_k$ and $\beta_l$ respectively, satisfying Assumption 1. Then, given a tuple of objects $(E_1, E_3) \in \mathcal{S}_x^{(\beta_k, 1)} \times \mathcal{S}_x^{(\beta_l, 1)}$, the following is true:

$$\text{Hom}(E_3, E_1) = \mathbb{A}^1 \quad \text{if} \quad E_1 \cong E_3,$$

and

$$\text{Hom}(E_3, E_1) = 0 \quad \text{if} \quad E_1 \ncong E_3.$$

Proof This is mainly due to the assumption on the stability of the sheaves involved. Fix $E_1 = [\mathcal{O}_X(-n) \rightarrow F_1] \in \mathcal{S}_x^{(\beta_k, 1)}$ and $E_3 = [\mathcal{O}_X(-n) \rightarrow F_3] \in \mathcal{S}_x^{(\beta_l, 1)}$. Consider a map $\psi: E_1 \rightarrow E_3$. By definition, the morphism between $E_1$ and $E_3$ is defined by a morphism $\psi_F: F_1 \rightarrow F_3$ which makes the following diagram commutative:

$$\begin{array}{ccc}
\mathcal{O}_X(-n) & \rightarrow & F_1 \\
\downarrow \text{id}_{\mathcal{O}_X} & & \downarrow \psi_F \\
\mathcal{O}_X(-n) & \rightarrow & F_3.
\end{array}$$

(23)

By assumption, $F_1$ and $F_3$ are given as stable sheaves with fixed reduced Hilbert polynomial $p$. Hence any nontrivial sheaf homomorphism from $F_1$ to $F_3$ is an isomorphism. Moreover by simplicity of stable sheaves any such nontrivial isomorphism is identified with $\mathbb{A}^1$. Now use the commutativity of the diagram in (23). \qed
Given a reducible class $\beta$, there might be multiple ways to decompose it into underlying smaller classes $\beta_k$ and $\beta_l$. We will now show that having fixed a class $\beta$ and moving from one decomposition type, say $\beta = \beta_k + \beta_l$, to another given by $\beta = \beta_{k'} + \beta_{l'}$, will correspond to moving from one stratum to another in the ambient moduli space of $E_2$, such that the corresponding strata are disjoint from one another.

**Lemma 3** Fix $\beta_k$ and $\beta_l$ such that $\beta_k + \beta_l = \beta$ and $\beta, \beta_k$ and $\beta_l$ satisfy the condition in Assumption 1. Consider an object $E_2$ given as an element of $S_2^{(\beta, 1)}$ (by this notation we mean that an object $E_2$ may consist of a semistable sheaf with reducible class $\beta$, which fits into a non-split extension of objects

$$0 \rightarrow E_1 \rightarrow E_2 \rightarrow E_3 \rightarrow 0,$$

such that $E_1$ and $E_3$ are given by the elements of $S_k^{(\beta_k, 1)}$ and $S_l^{(\beta_l, 1)}$ respectively. Now suppose $E'_1$ and $E'_3$ are objects with classes $(\beta_k', 1)$ and $(\beta_l', 1)$ respectively such that $\beta_k' + \beta_l' = \beta, \beta_k' \neq \beta_k, \beta_l' \neq \beta_l$ and furthermore, $\beta, \beta_k'$ and $\beta_l'$ also satisfy the condition in Assumption 1. Then it is true that $E_2$ cannot be given as an extension

$$0 \rightarrow E'_1 \rightarrow E_2 \rightarrow E'_3 \rightarrow 0.$$

**Proof** If $E_2$ is given by both extensions then we obtain a map between the two short exact sequences

$$
\begin{array}{ccc}
0 & \rightarrow & E_1 \\
\uparrow & & \uparrow \\
0 & \rightarrow & E'_1 \\
\end{array}
\quad
\begin{array}{ccc}
E_2 & \rightarrow & E_3 \\
\uparrow & & \uparrow \\
E'_2 & \rightarrow & E'_3 \\
\end{array}
\quad
\begin{array}{ccc}
\rightarrow & \rightarrow & 0 \\
\rightarrow & \rightarrow & 0.
\end{array}
$$

Hence we obtain a map $p \circ i : E_1 \rightarrow E'_1$. Since by assumption $\beta_k \neq \beta_k'$ (this means $\beta_l \neq \beta_l'$ because $\beta_k + \beta_l = \beta_k' + \beta_l' = \beta$), by Lemma 2, we conclude that $p \circ i$ is the zero map. Hence $p \circ i$ factors through the map $i' \circ g$ in the following diagram:

$$
\begin{array}{ccc}
0 & \rightarrow & E_1 \\
\downarrow & & \downarrow \\
0 & \rightarrow & E'_1
\end{array}
\quad
\begin{array}{ccc}
i' & \rightarrow & E_2 \\
\uparrow & & \uparrow \\
0 & \rightarrow & E'_2
\end{array}
\quad
\begin{array}{ccc}
\rightarrow & \rightarrow & E_3 \\
\rightarrow & \rightarrow & E'_3 \\
\rightarrow & \rightarrow & 0.
\end{array}
$$

Since $E_1 \neq E'_1$, by Lemma 2, $g$ is the zero map. By considering the left commutative square in (25) we obtain a contradiction, since the image of $E_1$ in $E_2$ cannot always be zero. $\square$

Now we show that flipping the order of non-split extensions will again induce disjoint parameterizing stratum in the ambient moduli space.
Lemma 4 Fix $\beta_k$ and $\beta_l$ such that $\beta_k + \beta_l = \beta$ as in Assumption 1. Now consider $E_2 \in \mathcal{S}_\text{ss}^{(\beta,2)}$ which fits into a non-split extension

$$0 \to E_1 \to E_2 \to E_3 \to 0,$$

where $E_1$ and $E_3$ are given by the elements of $\mathcal{S}_s^{(\beta_k,1)}$ and $\mathcal{S}_s^{(\beta_l,1)}$ respectively. Then the object $E_2$ cannot be given as an extension

$$0 \to E'_1 \to E_2 \to E'_3 \to 0,$$

where $[E'_1] = (\beta_l, 1)$ and $[E'_3] = (\beta_k, 1)$.

Proof We prove by contradiction. Assume $E_2$ fits in both exact sequences. We obtain a map between the two sequences

\[
\begin{array}{cccccc}
0 & \to & E_1 & \to & E_2 & \to & E_3 & \to & 0 \\
& & \uparrow \cong & & \downarrow & &  & \\
0 & \to & E'_1 & \to & E'_2 & \to & E'_3 & \to & 0.
\end{array}
\]

Similar to before, we obtain a map $p \circ i: E_1 \to E'_3$. Since $E_1$ and $E'_3$ have equal classes, we need to consider two possibilities. First when $E_1 \cong E'_3$ and second when $E_1 \not\cong E'_3$.

If $E_1 \cong E'_3$, then the image of the map $p \circ i$ is either multiple of identity over $E_1$ or the zero map. If the former case happens it means that the exact sequence on the first row is split, contradicting the assumption that $E_2$ fits in a non-split exact sequence. If the map is given by the zero map, then we can apply the argument in Lemma 3 and obtain a contradiction. If $E_1 \not\cong E'_3$ then the map $p \circ i$ is the zero map and the proof similarly reduces to argument in proof of Lemma 3. \qed

5 GL$_2(\mathbb{C})$-invariant stratification

Now we are ready to introduce a GL$_2(\mathbb{C})$-invariant stratification of $\mathcal{M}_{\beta_p, ss}^{(\beta,2)}(\tilde{\tau})$ for $\beta$ satisfying the condition in Assumption 1. Note that, by Theorem 1 and Definition 12,

$$\mathcal{M}_{\text{ss, ss}}^{(\beta,2)} = \frac{\mathcal{S}_s^{(\beta,2)}}{\text{GL}(V)}, \quad \mathcal{M}_{\beta_p, ss}^{(\beta,2)}(\tilde{\tau}) \subset \mathcal{M}_{\text{ss, ss}}^{(\beta,2)} = \left[ \frac{\mathcal{M}_{\beta_p, ss}^{(\beta,2)}}{\text{GL}_2(\mathbb{C})} \right],$$

which shows us that a suitable stratification of $\mathcal{S}_s^{(\beta,2)}$, after passing to the subsequent quotient stacks and restricting to the $\tilde{\tau}$-semistable locus, induces a GL$_2(\mathbb{C})$-invariant stratification of $\mathcal{M}_{\beta_p, ss}^{(\beta,2)}(\tilde{\tau})$. The cartoon below explains the intuition behind our strategy:
Strictly semistable objects in $\mathcal{M}_{\mathcal{B}_p,ss}(\tilde{\tau})$ and further stratifications

Now we pass to the subsequent quotients of $\mathcal{S}_{\mathcal{M}}^{(\beta,2)}$ (the picture above) and study the stratification of $\tilde{\tau}$-semistable loci in $\mathcal{M}_{\mathcal{B}_p,ss}^{(\beta,2)}$. These strata will be induced by the decomposition types of the objects involved. Note that in this section we provide only the description of the disjoint strata involved in our calculation and we assume that they are locally closed. The proof of locally closedness property of these strata is somewhat technical and so the interested reader may find the details in Appendix 10.

**Definition 20** Define $\mathcal{M}_{\mathcal{M},ss}^{(\beta,2)}(\tilde{\tau})$ to be the parametrizing scheme of strictly $\tilde{\tau}$-semistable objects in $\mathcal{B}_p$ of type $(\beta,2)$ (for $\beta$ as in Assumption 1) which are obtained as an extension of two $\tilde{\tau}$-stable objects of rank 1. In other words, an object $E_2 \in \mathcal{M}_{\mathcal{M},ss}^{(\beta,2)}(\tilde{\tau})$ with class $(\beta,2)$ fits in an exact sequence

$$0 \to E_1 \to E_2 \to E_3 \to 0,$$

where $E_1$ and $E_3$ are $\tilde{\tau}$-stable objects with classes $(\beta_k,1)$ and $(\beta_1,1)$ respectively for some $\beta_k$ and $\beta_1$ such that $\beta_k + \beta_1 = \beta$.

**Remark 5** Note that the existence of exact sequence (6) and the discussion in Sect. 3 show that all objects in $\mathcal{B}_p$ of type $(\beta,2)$ are strictly $\tilde{\tau}$-semistable. Hence $\mathcal{M}_{\mathcal{M},ss}^{(\beta,2)}(\tilde{\tau}) \cong \mathcal{M}_{\mathcal{B}_p,ss}^{(\beta,2)}(\tilde{\tau})$. 
If the extension in (24) is non-split then its automorphism group is obtained by \( \text{Hom}(E_3, E_1) \times \mathbb{G}_m \) and if split the automorphism group is obtained by \( \text{Hom}(E_3, E_1) \times \mathbb{G}_m^2 \) [10, p. 33]. We need these automorphism groups in order to compute the product \( * \) of the elements of the Ringe–Hall algebra. These elements are given as stack functions which parametrize objects of a given type (such as \((\beta_k, 1)\) or \((\beta_1, 1)\)). Now assume that the exact sequence in (24) is non-split and moreover \( E_1 \cong E_3 \). In this case since a semistable rank 1 object in \( \mathcal{M}_{\text{st-ss}}^{(\beta, 1)}(\tilde{\pi}) \) is also stable, by the property of \( \beta \) in Assumption 1 and Lemma 2, \( \text{Hom}(E_3, E_1) \cong \mathbb{A}^1 \) and the automorphism group of extension (24) is obtained by \( \mathbb{A}^1 \times \mathbb{G}_m \). Moreover if in (24), \( E_1 \not\cong E_3 \), then by Lemma 2, \( \text{Hom}(E_3, E_1) = 0 \) and the automorphism group of extension (24) is obtained by \( \mathbb{G}_m \).

Following similar argument for case of split extensions, we find that the automorphism group of the split extension is \( \mathbb{A}^1 \times \mathbb{G}_m^2 \) when \( E_1 \cong E_3 \) and \( \mathbb{G}_m^2 \) when \( E_1 \not\cong E_3 \). Therefore, first we decompose \( \mathcal{M}_{\text{st-ss}}^{(\beta, 2)}(\tilde{\pi}) \) into two disjoint strata

\[
\mathcal{M}_{\text{st-ss}}^{(\beta, 2)}(\tilde{\pi}) = \mathcal{M}_{\text{np-sp}}^{(\beta, 2)}(\tilde{\pi}) \sqcup \mathcal{M}_{\text{np}}^{(\beta, 2)}(\tilde{\pi}).
\]

Here \( \mathcal{M}_{\text{np-sp}}^{(\beta, 2)}(\tilde{\pi}) \) and \( \mathcal{M}_{\text{np}}^{(\beta, 2)}(\tilde{\pi}) \) stand for the strata over which the objects representing the elements in \( \mathcal{M}_{\text{st-ss}}^{(\beta, 2)}(\tilde{\pi}) \) are given by non-split and split extensions respectively. These strata are disjoint since an element \( E_2 \in \mathcal{M}_{\text{st-ss}}^{(\beta, 2)}(\tilde{\pi}) \) cannot be given by both split and non-split extensions. Now by Lemmas 3 and 4, \( \mathcal{M}_{\text{np-sp}}^{(\beta, 2)}(\tilde{\pi}) \) can further be stratified into a disjoint union over all possible \( \beta_k \) and \( \beta_l \):

\[
\mathcal{M}_{\text{np-sp}}^{(\beta, 2)}(\tilde{\pi}) = \bigsqcup_{\beta_k + \beta_l = \beta} \mathcal{M}_{\text{np-sp}}^{(\beta_k, \beta_l, 2)}(\tilde{\pi}),
\]

where \( \mathcal{M}_{\text{np-sp}}^{(\beta_k, \beta_l, 2)}(\tilde{\pi}) \) stands for stratum over which \( E_2 \) is obtained by a non-split extension of \( \tilde{\pi} \)-stable objects \( E_1 \) by \( E_3 \) with fixed classes \( (\beta_k, 1) \) and \( (\beta_l, 1) \) respectively. Now take one of these strata \( \mathcal{M}_{\text{np-sp}}^{(\beta_k, \beta_l, 2)}(\tilde{\pi}) \) by fixing \( \beta_k \) and \( \beta_l \). We claim that one may decompose this stratum further into two disjoint strata, depending on the values of \( \beta_k \) and \( \beta_l \) respectively.

- **Define** \( \mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\tilde{\pi}) \) to be the parametrizing stack of objects \( E_2 \in \mathcal{M}_{\text{np-sp}}^{(\beta_k, \beta_l, 2)}(\tilde{\pi}) \) such that there exists a non-split exact sequence \( 0 \to E_1 \to E_2 \to E_3 \to 0 \), where \( E_1 \in \mathcal{M}_{\text{np-sp}}^{(\beta_k, 1)}(\tilde{\pi}) \) and \( E_3 \in \mathcal{M}_{\text{np-sp}}^{(\beta_l, 1)}(\tilde{\pi}) \) and \( E_1 \not\cong E_3 \).

- **Define** \( \mathcal{M}_2^{(\beta_k, \beta_l, 2)}(\tilde{\pi}) \) to be the parametrizing stack of objects \( E_2 \in \mathcal{M}_{\text{np-sp}}^{(\beta_k, \beta_l, 2)}(\tilde{\pi}) \) such that there exists a non-split exact sequence \( 0 \to E_1 \to E_2 \to E_3 \to 0 \), where \( E_1, E_3 \in \mathcal{M}_{\text{np-sp}}^{(\beta, 2), 1}(\tilde{\pi}) \) and \( E_1 \cong E_3 \).

**Lemma 5** There exists a stratification of \( \mathcal{M}_{\text{np-sp}}^{(\beta_k, \beta_l, 2)}(\tilde{\pi}) \):

\[
\mathcal{M}_{\text{np-sp}}^{(\beta_k, \beta_l, 2)}(\tilde{\pi}) = \mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\tilde{\pi}) \sqcup \mathcal{M}_2^{(\beta_k, \beta_l, 2)}(\tilde{\pi}).
\]
Proof We show that $\mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\tilde{\tau})$ and $\mathcal{M}_2^{(\beta_k, \beta_l, 2)}(\tilde{\tau})$ are disjoint. Assume that

$$\mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\tilde{\tau}) \cap \mathcal{M}_2^{(\beta_k, \beta_l, 2)}(\tilde{\tau}) \neq \emptyset.$$ 

Therefore, there exists an object $E_2 \in \mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\tilde{\tau})$ which fits in exact sequences

$$0 \to E_1 \to E_2 \to E_3 \to 0 \quad \text{and} \quad 0 \to E'_1 \to E'_2 \to E'_3 \to 0,$$

such that $E_1 \not\cong E_3$ and $E'_1 \cong E'_3$. Hence, one obtains a map $p \circ \iota: E_1 \to E'_3$ via the following diagram:

$$0 \to E_1 \to E_2 \to E_3 \to 0 \quad \text{and} \quad 0 \to E'_1 \to E'_2 \to E'_3 \to 0.$$

If $E_1 \cong E'_3$, then the image of $p \circ \iota$ is multiple of identity over $E_1$ or the zero map. For the former case we conclude that the first row splits, hence a contradiction. If $p \circ \iota$ is the zero map, then $p \circ \iota$ factors through the map $\iota \circ g$ in the following diagram:

$$0 \to E_1 \to E_2 \to E_3 \to 0 \quad \text{and} \quad 0 \to E'_1 \to E'_2 \to E'_3 \to 0.$$

Since $E_1 \cong E'_3$ and $E'_1 \cong E'_3$, then $E_1 \cong E'_1$ and we conclude one of the following possibilities: either $\iota$ and $\iota'$ are both given as zero maps which is over-ruled (since $\iota$ and $\iota'$ are both injections) or the map $g$ is zero which is obviously over-ruled. Moreover if the map $g$ is an isomorphism then $E_3 \cong E'_3$ and since $E_1 \cong E'_1$ by assumption, then $E_1 \cong E_3$ which is a contradiction. Therefore, we assume $E_1 \not\cong E'_3$. In this case $p \circ \iota \in \text{Hom}(E_1, E'_3)$ which is the zero map by Lemma 2. Then similarly $p \circ \iota$ factors through the map $\iota \circ g$ in diagram (25). Since $E'_1 \cong E'_3$ and $E_1 \not\cong E'_3$, then $E_1 \not\cong E'_3$ and, by Lemma 2, $g$ is the zero map. By considering the left commutative square in (25), we obtain a contradiction since the image of $E_1$ in $E_2$ is nonzero. Therefore $\mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\tilde{\tau}) \cap \mathcal{M}_2^{(\beta_k, \beta_l, 2)}(\tilde{\tau}) = \emptyset$.

So far we have proved

$$\mathcal{M}_1^{(\beta, 2)}(\tilde{\tau}) = \bigcup_{\beta_k + \beta_l = \beta} \left( \mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\tilde{\tau}) \cup \mathcal{M}_2^{(\beta_k, \beta_l, 2)}(\tilde{\tau}) \right).$$

Now consider the split stratum $\mathcal{M}_1^{(\beta, 2)}(\tilde{\tau})$. We similarly decompose this stratum further, depending on the values of $\beta_k, \beta_l$.

- Define $\mathcal{M}_2^{(\beta, 2)}(\tilde{\tau})$ to be the parametrizing stack of objects $E_2 \in \mathcal{M}_2^{(\beta, 2)}(\tilde{\tau})$ such that

$$E_2 \cong E_1 \oplus E_3,$$

where $E_1, E_3 \in \mathcal{M}_3^{(\beta/2, 1)}(\tilde{\tau})$ and $E_1 \cong E_3$. 

Weighted Euler characteristic of the moduli space of higher rank Joyce–Song pairs 29
• Define $\mathcal{M}^{(\beta_k, \beta_l, 2)}_{O-La}(\bar{\tau})$ to be the parametrizing stack of objects $E_2 \in \mathcal{M}^{(\beta, 2)}_{\beta}(\bar{\tau})$ such that

$$E_2 \cong E_1 \oplus E_3,$$

where $E_1 \in \mathcal{M}^{(\beta_k, 1)}_{2p, ss}, E_3 \in \mathcal{M}^{(\beta_l, 1)}_{2p, ss}$ and $E_1 \neq E_3$.

By the same argument as in Lemma 5, we see that

$$\mathcal{M}^{(\beta, 2)}_{\beta}(\bar{\tau}) = \mathcal{M}^{(\beta, 2)}_{\beta}(\bar{\tau}) \cup \mathcal{M}^{(\beta_k, \beta_l, 2)}_{O-La}(\bar{\tau}).$$

The above arguments enable us to give a stratification of $\mathcal{M}^{(\beta, 2)}_{\beta}(\bar{\tau})$:

$$\mathcal{M}^{(\beta, 2)}_{\beta}(\bar{\tau}) = \bigcup_{\beta_k + \beta_l = \beta}^0 (\mathcal{M}^{(\beta_k, \beta_l, 2)}_{\beta}(\bar{\tau}) \cup \mathcal{M}^{(\beta_k, \beta_l, 2)}_{O-La}(\bar{\tau}))$$

$$\cup \bigcup_{\beta_k + \beta_l = \beta}^{u-o} (\mathcal{M}^{(\beta_k, \beta_l, 2)}_{O-La}(\bar{\tau}) \cup \mathcal{M}^{(\beta, 2)}_{\beta}(\bar{\tau})). \quad (26)$$

Here $\bigcup_{\beta_k + \beta_l = \beta}^0$ and $\bigcup_{\beta_k + \beta_l = \beta}^{u-o}$ stand for ordered and un-ordered disjoint unions respectively. The latter notation makes sense because for non-split extensions it is important which of the two classes $\beta_k, \beta_l$ appear first (flipping the order of a non-split extension would mean obtaining a different stratum), while for split extensions flipping the order of appearance of $\beta_k, \beta_l$ will not make any change.

We introduce a new notation. Fix $\beta_k$ and $\beta_l$ such that $\beta_k + \beta_l = \beta$. Let $\mathcal{D}^{(\beta_k, \beta_l, 2)}(\bar{\tau})$ be the parametrizing stack of objects $E_2 \cong E_1 \oplus E_3$ such that $(E_1, E_3) \in \mathcal{M}^{(\beta_k, 1)}_{2p, ss} \times \mathcal{M}^{(\beta_l, 1)}_{2p, ss}$ and $E_1 \cong E_3$. It is obvious from the definition that if $\beta_k \neq \beta_l$ then $\mathcal{D}^{(\beta_k, \beta_l, 2)}(\bar{\tau}) = \emptyset$ and for $\beta_k = \beta_l = \beta/2$, $\mathcal{D}^{(\beta_k, \beta_l, 2)}(\bar{\tau}) = \mathcal{M}^{(\beta, 2)}_{\beta}(\bar{\tau})$. Using this new notation,

$$\mathcal{M}^{(\beta, 2)}_{\beta}(\bar{\tau}) = \bigcup_{\beta_k + \beta_l = \beta} \mathcal{D}^{(\beta_k, \beta_l, 2)}(\bar{\tau})$$

and by (26) we obtain

$$\mathcal{M}^{(\beta, 2)}_{\beta}(\bar{\tau}) = \bigcup_{\beta_k + \beta_l = \beta}^0 (\mathcal{M}^{(\beta_k, \beta_l, 2)}_{\beta}(\bar{\tau}) \cup \mathcal{M}^{(\beta_k, \beta_l, 2)}_{O-La}(\bar{\tau}))$$

$$\cup \bigcup_{\beta_k + \beta_l = \beta}^{u-o} (\mathcal{M}^{(\beta_k, \beta_l, 2)}_{O-La}(\bar{\tau}) \cup \mathcal{D}^{(\beta_k, \beta_l, 2)}(\bar{\tau})). \quad (27)$$

6 The element of the Hall algebra of $\mathcal{M}^{(\beta, 2)}_{2p, ss}(\bar{\tau})$

**Definition 21** Define functions $\overline{\tau}^{(\beta, 2)}_{\beta}(\bar{\tau}), \overline{\tau}^{(\beta_k, \beta_l, 2)}_{\beta}(\bar{\tau}), \overline{\tau}^{(\beta_k, \beta_l, 2)}_{O-La}(\bar{\tau}), \overline{\tau}^{(\beta_k, \beta_l, 2)}_{La}(\bar{\tau})$ and $\overline{\tau}^{(\beta_k, \beta_l, 2)}_{D}(\bar{\tau})$ to be the characteristic stack functions of $\mathcal{M}^{(\beta, 2)}_{\beta}(\bar{\tau}) \cong \mathcal{M}^{(\beta, 2)}_{2p, ss}(\bar{\tau})$, $\mathcal{M}^{(\beta_k, \beta_l, 2)}_{\beta}(\bar{\tau}), \mathcal{M}^{(\beta_k, \beta_l, 2)}_{O-La}(\bar{\tau})$ and $\mathcal{D}^{(\beta_k, \beta_l, 2)}(\bar{\tau})$ respectively.

---

4 The notation $\Delta$ and $O-\Delta$ stand for diagonal and off-diagonal respectively.
Then, by Definition 21 and (27) the following identity is true:

\[
\bar{\tau}_{\text{ss}}^{(\beta, 2)}(\bar{\tau}) = \sum_{\beta_k + \beta_l = \beta}^\infty (\bar{\delta}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau}) + \bar{\delta}_2^{(\beta_k, \beta_l, 2)}(\bar{\tau})) + \sum_{\beta_k + \beta_l = \beta}^{\text{u-o}} (\bar{\delta}_3^{(\beta_k, \beta_l, 2)}(\bar{\tau}) + \bar{\delta}_4^{(\beta_k, \beta_l, 2)}(\bar{\tau})),
\]

where \(\sum_{\beta_k + \beta_l = \beta}^\infty\) and \(\sum_{\beta_k + \beta_l = \beta}^{\text{u-o}}\) denote the ordered and un-ordered sums respectively. However by construction, \(\bar{\tau}_{\text{ss}}^{(\beta_k, \beta_l, 2)}(\bar{\tau}) = \bar{\tau}_{\text{ss}}^{(\beta_k, \beta_l, 2)}(\bar{\tau}) = \emptyset\) whenever \(\beta_k \neq \beta_l\), hence we obtain

\[
\bar{\tau}_{\text{ss}}^{(\beta, 2)}(\bar{\tau}) = \sum_{\beta_k + \beta_l = \beta}^\infty (\bar{\delta}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau}) + \bar{\delta}_2^{(\beta, 2, \beta/2, 2)}(\bar{\tau})) + \sum_{\beta_k + \beta_l = \beta}^{\text{u-o}} (\bar{\delta}_3^{(\beta_k, \beta_l, 2)}(\bar{\tau}) + \bar{\delta}_4^{(\beta/2, 2, \beta/2, 2)}(\bar{\tau})).
\]

On the other hand, by applying Definition 13 to \(\mathfrak{M}^{(\beta, 2)}_{\text{ss}}(\bar{\tau})\), we obtain the following description of the element of the Hall algebra:

\[
\tau^{(\beta, 2)}(\bar{\tau}) = \bar{\tau}_{\text{ss}}^{(\beta, 2)}(\bar{\tau}) - \sum_{\beta_k + \beta_l = \beta}^\infty \frac{1}{2} \bar{\delta}_2^{(\beta_k, 1)}(\bar{\tau}) \# \bar{\delta}_4^{(\beta_l, 1)}(\bar{\tau}).
\]

Now, by (28) and (29), we obtain

\[
\tau^{(\beta, 2)}(\bar{\tau}) = \sum_{\beta_k + \beta_l = \beta}^\infty (\bar{\delta}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau}) + \bar{\delta}_2^{(\beta, 2, \beta/2, 2)}(\bar{\tau})) + \sum_{\beta_k + \beta_l = \beta}^{\text{u-o}} \bar{\delta}_3^{(\beta_k, \beta_l, 2)}(\bar{\tau}) + \bar{\delta}_4^{(\beta/2, 2, \beta/2, 2)}(\bar{\tau}) - \sum_{\beta_k + \beta_l = \beta}^\infty \frac{1}{2} \bar{\delta}_2^{(\beta_k, 1)}(\bar{\tau}) \# \bar{\delta}_4^{(\beta_l, 1)}(\bar{\tau}).
\]

It is easily seen that

\[
\sum_{\beta_k + \beta_l = \beta}^{\text{u-o}} \bar{\delta}_3^{(\beta_k, \beta_l, 2)}(\bar{\tau}) = \bar{\delta}_3^{(\beta/2, 2, \beta/2, 2)}(\bar{\tau}) + \frac{1}{2} \sum_{\beta_k + \beta_l = \beta}^\infty \bar{\delta}_3^{(\beta_k, \beta_l, 2)}(\bar{\tau}).
\]

Hence, we rewrite the right-hand side of (30) as

\[
\tau^{(\beta, 2)}(\bar{\tau}) = \sum_{\beta_k + \beta_l = \beta}^\infty (\bar{\delta}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau}) + \bar{\delta}_2^{(\beta, 2, \beta/2, 2)}(\bar{\tau}) + \bar{\delta}_3^{(\beta/2, 2, \beta/2, 2)}(\bar{\tau}))
\]

\[
+ \frac{1}{2} \sum_{\beta_k + \beta_l = \beta}^\infty \bar{\delta}_3^{(\beta_k, \beta_l, 2)}(\bar{\tau})
\]

\[
+ \bar{\delta}_4^{(\beta/2, 2, \beta/2, 2)}(\bar{\tau})
\]

\[
- \sum_{\beta_k + \beta_l = \beta}^\infty \frac{1}{2} \bar{\delta}_2^{(\beta_k, 1)}(\bar{\tau}) \# \bar{\delta}_4^{(\beta_l, 1)}(\bar{\tau}).
\]
Next we compute the ordered product $\delta^i_{\beta_k, 1}(\tilde{\tau}) \ast \delta^i_{\beta_l, 1}(\tilde{\tau})$ for a fixed choice of $\beta_k$ and $\beta_l$.

7 Computation of $\delta^i_{\beta_k, 1}(\tilde{\tau}) \ast \delta^i_{\beta_l, 1}(\tilde{\tau})$

In this section we describe the computation of the Ringel–Hall product of the stack functions $\delta^i_{\beta_k, 1}(\tilde{\tau}) \ast \delta^i_{\beta_l, 1}(\tilde{\tau})$ for $\beta_k$ and $\beta_l$ satisfying the condition in Assumption 1. Similar to discussions in Sect. 3, let $\pi_i; \mathcal{E} \text{ract}_{\mathcal{B}_p} \to \mathcal{M}_{\mathcal{B}_p}(\tilde{\tau})$, for $i = 1, 2, 3$, be the projection map that sends an exact sequence

$$0 \to E_1 \to E_2 \to E_3 \to 0$$

to its first, second and third objects respectively over moduli stack of objects in $\mathcal{B}_p$. We also have the map $\pi_1 \times \pi_3; \mathcal{E} \text{ract}_{\mathcal{B}_p} \to \mathcal{M}_{\mathcal{B}_p}(\tilde{\tau}) \times \mathcal{M}_{\mathcal{B}_p}(\tilde{\tau})$. By the Joyce and Song definition in [10, Definition 3.3],

$$\delta^i_{\beta_k, 1}(\tilde{\tau}) \ast \delta^i_{\beta_l, 1}(\tilde{\tau}) = \pi_2 \ast ((\pi_1 \times \pi_3)^* (\delta^i_{\beta_k, 1}(\tilde{\tau}) \otimes \delta^i_{\beta_l, 1}(\tilde{\tau}))).$$

(32)

Suppose that

$$\delta^i_{\beta_k, 1} = \begin{bmatrix} \mathcal{M}(\beta_k, 1)(\tilde{\tau}) \end{bmatrix}_{\mathbb{G}_m, \rho_1} \quad \text{and} \quad \delta^i_{\beta_l, 1} = \begin{bmatrix} \mathcal{M}(\beta_l, 1)(\tilde{\tau}) \end{bmatrix}_{\mathbb{G}_m, \rho_3},$$

where $\mathcal{M}(\beta_k, 1)(\tilde{\tau})$ and $\mathcal{M}(\beta_l, 1)(\tilde{\tau})$ denote some underlying parameter schemes and

$$\rho_1; \begin{bmatrix} \mathcal{M}(\beta_k, 1)(\tilde{\tau}) \end{bmatrix}_{\mathbb{G}_m} \to \mathcal{M}_{\mathcal{B}_p}(\tilde{\tau}), \quad \rho_3; \begin{bmatrix} \mathcal{M}(\beta_l, 1)(\tilde{\tau}) \end{bmatrix}_{\mathbb{G}_m} \to \mathcal{M}_{\mathcal{B}_p}(\tilde{\tau}).$$

Let us denote by $\mathcal{Z}'$ the fibered product

$$\left( \begin{bmatrix} \mathcal{M}(\beta_k, 1)(\tilde{\tau}) \end{bmatrix}_{\mathbb{G}_m} \times \begin{bmatrix} \mathcal{M}(\beta_l, 1)(\tilde{\tau}) \end{bmatrix}_{\mathbb{G}_m} \right) \times_{\rho_1 \times \rho_3; \mathcal{M}_{\mathcal{B}_p}(\tilde{\tau}) \times \mathcal{M}_{\mathcal{B}_p}(\tilde{\tau}), \pi_1 \times \pi_3; \mathcal{E} \text{ract}_{\mathcal{B}_p}}.$$

The identity in (32) is described by $(\pi_2 \circ \Phi)_* \mathcal{Z}'$ in the following diagram:

$$\begin{array}{ccc}
\mathcal{Z}' & \xrightarrow{\Phi} & \mathcal{E} \text{ract}_{\mathcal{B}_p} \\
\downarrow \left[ \begin{bmatrix} \mathcal{M}(\beta_k, 1)(\tilde{\tau}) \end{bmatrix}_{\mathbb{G}_m} \times \begin{bmatrix} \mathcal{M}(\beta_l, 1)(\tilde{\tau}) \end{bmatrix}_{\mathbb{G}_m} \right]_{\rho_1 \times \rho_3} & \xrightarrow{\pi_1 \times \pi_3} & \mathcal{M}_{\mathcal{B}_p}(\tilde{\tau}) \\
\mathcal{M}_{\mathcal{B}_p}(\tilde{\tau}) \times \mathcal{M}_{\mathcal{B}_p}(\tilde{\tau}) & \xrightarrow{\mathcal{E} \text{ract}_{\mathcal{B}_p}} & \mathcal{M}_{\mathcal{B}_p}(\tilde{\tau}).
\end{array}$$

We compute the product of stack functions in (32) by computing it over the $\mathbb{C}$-points of $\delta^i_{\beta_k, 1}(\tilde{\tau})$ and $\delta^i_{\beta_l, 1}(\tilde{\tau})$ (these are induced from $\mathbb{C}$-points of $\mathcal{M}(\beta_k, 1)(\tilde{\tau})$ and $\mathcal{M}(\beta_l, 1)(\tilde{\tau})$) and then integrating over all points in $\mathcal{M}(\beta_k, 1)(\tilde{\tau}) \times \mathcal{M}(\beta_l, 1)(\tilde{\tau})$. 
7.0.1 Pointwise products

Consider the stack function
\[ \delta_1 = \left( \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m}, \rho_1 \circ \iota_1 \right), \quad \text{with} \quad \iota_1 : \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \to \frac{\mathcal{M}(\beta_k,1)_{(\tilde{\tau})}}{\mathbb{G}_m}. \]
Moreover let
\[ \delta_3 = \left( \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m}, \rho_3 \circ \iota_3 \right), \quad \text{with} \quad \iota_3 : \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \to \frac{\mathcal{M}(\beta_l,1)_{(\tilde{\tau})}}{\mathbb{G}_m}. \]

Note that \( \delta_1 \subset \delta_1(\beta_k,1)_{(\tilde{\tau})} \) and \( \delta_3 \subset \delta_3(\beta_l,1)_{(\tilde{\tau})} \) are the substack functions, induced by taking the stacky quotients of \( \mathbb{C} \)-points of \( \mathcal{M}(\beta_k,1)_{(\tilde{\tau})} \) and \( \mathcal{M}(\beta_l,1)_{(\tilde{\tau})} \) respectively.

Let \( E_1 \in \mathcal{M}(\beta_k,1)_{(\tilde{\tau})}, E_3 \in \mathcal{M}(\beta_l,1)_{(\tilde{\tau})} \) and \( E_2 \in \mathcal{M}(\beta_2,1)_{(\tilde{\tau})} \). Consider the exact sequence in \( \text{Ext}_{\mathfrak{m}^2_p} \)
\[ 0 \to E_1 \to E_2 \to E_3 \to 0. \quad (33) \]
The automorphism group of the extension (33) is given by \( \text{Hom}(E_3, E_1) \rtimes \mathbb{G}_m^2 \). The element \((g_1, g_2) \in \mathbb{G}_m^2\) acts on \( \text{Ext}^1(E_3, E_1) \) by multiplication by \( g_2^{-1} g_1 \) and the action of \( \text{Hom}(E_3, E_1) \) on \( \text{Ext}^1(E_3, E_1) \) is trivial. If extensions in (33) are non-split, then the parametrizing scheme of such extensions is obtained by \( \mathbb{P}(\text{Ext}^1(E_3, E_1)) \) and for split extensions, it is obtained by \( \text{Spec}(\mathbb{C}) \). In case of non-split extensions, the stabilizer group of the action of \( \mathbb{G}_m^2 \) is given by \( \mathbb{G}_m \) and for split extensions, the stabilizer group of the action of \( \mathbb{G}_m^2 \) is \( \mathbb{G}_m^2 \) itself, hence
\[ \delta_1 \ast \delta_3 = \left( \frac{\text{Spec}(\mathbb{C})}{\text{Hom}(E_3, E_1) \rtimes \mathbb{G}_m^2}, \mu_1 \right) + \left( \frac{\mathbb{P}(\text{Ext}^1(E_3, E_1))}{\text{Hom}(E_3, E_1) \rtimes \mathbb{G}_m^2}, \mu_3 \right). \quad (34) \]

7.0.2 Motivic integration over points

Now we can integrate the right-hand side of (34) over \( \mathbb{C} \)-points of \( \mathcal{M}(\beta_k,1)_{(\tilde{\tau})} \) and \( \mathcal{M}(\beta_l,1)_{(\tilde{\tau})} \) respectively. Let us define/recall such notion of integration.

**Definition 22** Let \( \mathfrak{R} \) be a \( \mathbb{C} \)-stack given by
\[ \mathfrak{R} = \left[ \frac{\mathcal{M}}{G} \right]. \]
Let \( \mathbb{B}G \) denote the quotient stack
\[ \left[ \frac{\text{Spec}(\mathbb{C})}{G} \right]. \]
Now define **motivic integration over \( \mathfrak{R} \)** as an identity in the motivic ring of stack functions
\[ \int_{\mathcal{M}} \left[ \frac{\text{Spec}(\mathbb{C})}{G} \right] \ d\mu_m = \left[ \frac{\mathfrak{R}}{G} \right]. \]
Moreover assume that $P \to \mathcal{M}$ is a vector bundle over $\mathcal{M}$. Then define

$$
\int_{\mathcal{M}} \left[ \frac{P}{G} \right] d\mu_m = \int_{\mathcal{M}} \chi(P) \cdot \left[ \frac{\text{Spec}(\mathbb{C})}{G} \right] d\mu_m = \chi(P) \cdot \left[ \frac{\mathcal{M}}{G} \right],
$$

where $\chi(P)$ denotes the topological Euler characteristic of $P$. Here, the *measure* $\mu_m$ is the map sending constructible sets on $\mathcal{M}$ to the their corresponding elements in the Grothendieck group of stacks.

Now we use Definition 22 to **motivically integrate** (34) over the points of $\mathcal{M}(\beta_k,1)(\tilde{t}) \times \mathcal{M}(\beta_l,1)(\tilde{t})$:

$$
\mathcal{M}(\beta_k,1)(\tilde{t}) \times \mathcal{M}(\beta_l,1)(\tilde{t}) = \int (E_1, E_2) \in \mathcal{M}(\beta_k,1)(\tilde{t}) \times \mathcal{M}(\beta_l,1)(\tilde{t}) \delta_1 \delta_2 d\mu_m
$$

$$
= \int (E_1, E_2) \in \mathcal{M}(\beta_k,1)(\tilde{t}) \times \mathcal{M}(\beta_l,1)(\tilde{t}) \left[ \frac{\text{Spec}(\mathbb{C})}{\text{Hom}(E_3, E_1) \times \mathbb{G}_m^2} \right] d\mu_m
$$

$$
+ \int (E_1, E_2) \in \mathcal{M}(\beta_k,1)(\tilde{t}) \times \mathcal{M}(\beta_l,1)(\tilde{t}) \left[ \frac{\text{Ext}^1(E_3, E_1)}{\text{Hom}(E_3, E_1) \times \mathbb{G}_m} \right] d\mu_m. \tag{35}
$$

By the result of Lemma 2, if $t_1 = t_3$, i.e. if $E_1 \cong E_3$, then $\text{Hom}(E_3, E_1) \cong \mathbb{A}^1$ and if $t_1 \neq t_3$, then $\text{Hom}(E_3, E_1) = \text{Spec}(\mathbb{C})$, hence we can evaluate the first summand on the right-hand side (35) as follows:

$$
\int (E_1, E_2) \in \mathcal{M}(\beta_k,1)(\tilde{t}) \times \mathcal{M}(\beta_l,1)(\tilde{t}) \left[ \frac{\text{Spec}(\mathbb{C})}{\text{Hom}(E_3, E_1) \times \mathbb{G}_m^2} \right] d\mu_m
$$

$$
= \int \Delta \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{A}^1 \times \mathbb{G}_m^2} \right] d\mu_m
$$

$$
+ \int \mathcal{M}(\beta_k,1)(\tilde{t}) \times \mathcal{M}(\beta_l,1)(\tilde{t}) \Delta \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m^2} \right] d\mu_m \tag{36}
$$

Here $\Delta$ is the diagonal in the product $\mathcal{M}(\beta_k,1)(\tilde{t}) \times \mathcal{M}(\beta_l,1)(\tilde{t})$. Similarly for the second summand on the right-hand side of (35) we obtain

$$
\int (E_1, E_2) \in \mathcal{M}(\beta_k,1)(\tilde{t}) \times \mathcal{M}(\beta_l,1)(\tilde{t}) \left[ \frac{\text{Ext}^1(E_3, E_1)}{\text{Hom}(E_3, E_1) \times \mathbb{G}_m} \right] d\mu_m
$$

$$
= \int \mathcal{M}(\beta_k,1)(\tilde{t}) \left[ \frac{\text{Ext}^1(E_3, E_1)}{\mathbb{A}^1 \times \mathbb{G}_m} \right] d\mu_m \tag{37}
$$

$$
+ \int \mathcal{M}(\beta_k,1)(\tilde{t}) \times \mathcal{M}(\beta_l,1)(\tilde{t}) \Delta \left[ \frac{\text{Ext}^1(E_3, E_1)}{\mathbb{G}_m} \right] d\mu_m.$$
From (35), (36) and (37) we obtain

\[
\bar{\delta}_s (\beta_{k,1}) (\bar{\tau}) \ast \bar{\delta}_s (\beta_{l,1}) (\bar{\tau}) = \left[ \mathcal{M}^{(\beta/2,1)} (\bar{\tau}) \times \mathcal{M}^{(\beta,1)} (\bar{\tau}) \right]_{\mathbb{G}_m^2} + \int_{\mathcal{M}^{(\beta/2,1)} (\bar{\tau}) \times \mathcal{M}^{(\beta,1)} (\bar{\tau})} \left[ \mathbb{P}(\operatorname{Ext}^1(E_1, E_3)) \right] d\mu_m \]

Equation (38) was obtained by fixing the classes \( \beta_k, \beta_l \) and adding motivically over the points of the underlying parameterizing schemes, i.e. adding the contribution of all sheaves with the same fixed numerical classes. Now, the final step to complete the calculation is to vary the classes \( \beta_k, \beta_l \) as long as \( \beta_k + \beta_l = \beta \).

\[
\sum_{\beta_k + \beta_l = \beta} \bar{\delta}_s (\beta_{k,1}) (\bar{\tau}) \ast \bar{\delta}_s (\beta_{l,1}) (\bar{\tau}) = \sum_{\beta_k + \beta_l = \beta} \int_{\mathcal{M}^{(\beta/2,1)} (\bar{\tau}) \times \mathcal{M}^{(\beta,1)} (\bar{\tau})} \left[ \mathbb{P}(\operatorname{Ext}^1(E_1, E_3)) \right] d\mu_m \]

It is easily seen that

\[
\sum_{\beta_k + \beta_l = \beta} \left[ \mathcal{M}^{(\beta_{k,1}) (\bar{\tau}) \times \mathcal{M}^{(\beta_{l,1}) (\bar{\tau}) \Delta} \right] = \left[ \mathcal{M}^{(\beta/2,1)} (\bar{\tau}) \times \mathcal{M}^{(\beta,1)} (\bar{\tau}) \Delta \right]_{\mathbb{G}_m^2} + \sum_{\beta_k + \beta_l = \beta} \left[ \mathcal{M}^{(\beta_{k,1}) (\bar{\tau}) \times \mathcal{M}^{(\beta_{l,1}) (\bar{\tau})} \Delta \right].
\]
Hence
\[
\sum_{\beta_k + \beta_l = \beta}^\circ \delta_s^{(\beta_k, 1)}(\bar{\tau}) * \delta_s^{(\beta_l, 1)}(\bar{\tau}) = \sum_{\beta_k + \beta_l = \beta}^\circ \int_{M(\beta_k, 1)(\bar{\tau}) \times M(\beta_l, 1)(\bar{\tau}) \Delta} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_3, E_1))}{G_m} \right] d\mu_m \\
+ \int_{M(\beta, 2, 1)(\bar{\tau})} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_1, E_1))}{A^1 \times G_m} \right] d\mu_m \\
+ \frac{1}{2} \int_{M(\beta, 2, 1)(\bar{\tau}) \times M(\beta, 2, 1)(\bar{\tau}) \Delta} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_1, E_1))}{G_m^2} \right] d\mu_m \\
+ \sum_{\beta_k + \beta_l = \beta}^\circ \frac{1}{2} \int_{M(\beta_k, 1)(\bar{\tau}) \times M(\beta_l, 1)(\bar{\tau}) \Delta} \left[ \mathbb{P}(\text{Ext}^1(E_1, E_1)) \right] d\mu_m.
\]

By (31) and the above equation, we obtain
\[
\tau^{(\beta, 2)}(\bar{\tau}) = \sum_{\beta_k + \beta_l = \beta}^\circ \left( \delta_s^{(\beta_k, \beta_l, 2)}(\bar{\tau}) - \frac{1}{2} \int_{M(\beta_k, 1)(\bar{\tau}) \times M(\beta_l, 1)(\bar{\tau}) \Delta} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_3, E_1))}{G_m} \right] d\mu_m \\
+ \delta_s^{(\beta, 2, 2)}(\bar{\tau}) - \frac{1}{2} \int_{M(\beta, 2, 1)(\bar{\tau})} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_1, E_1))}{A^1 \times G_m} \right] d\mu_m \\
+ \frac{1}{2} \int_{M(\beta, 2, 1)(\bar{\tau}) \times M(\beta, 2, 1)(\bar{\tau}) \Delta} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_1, E_1))}{G_m^2} \right] d\mu_m \\
+ \sum_{\beta_k + \beta_l = \beta}^\circ \frac{1}{2} \int_{M(\beta_k, 1)(\bar{\tau}) \times M(\beta_l, 1)(\bar{\tau}) \Delta} \left[ \mathbb{P}(\text{Ext}^1(E_1, E_1)) \right] d\mu_m \right).
\]

We introduce a new notation which simplifies the right-hand side of (39). Let
\[
\epsilon_i^{(k, 1)}(\bar{\tau}) = \tau_i^{(k, 1)}(\bar{\tau}) - \frac{1}{2} \int_{M(\beta_k, 1)(\bar{\tau}) \times M(\beta_l, 1)(\bar{\tau}) \Delta} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_3, E_1))}{G_m} \right] d\mu_m,
\]
\[
\epsilon_i^{(1/2, 1)}(\bar{\tau}) = \tau_i^{(1/2, 1)}(\bar{\tau}) - \frac{1}{2} \int_{M(\beta, 2, 1)(\bar{\tau})} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_1, E_1))}{A^1 \times G_m} \right] d\mu_m,
\]
\[
\epsilon_i^{(1, 1/2)}(\bar{\tau}) = \tau_i^{(1, 1/2)}(\bar{\tau}) - \frac{1}{2} \int_{M(\beta, 2, 1)(\bar{\tau}) \times M(\beta, 2, 1)(\bar{\tau}) \Delta} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_1, E_1))}{G_m^2} \right] d\mu_m,
\]
\[
\epsilon_i^{(k, 1)}(\bar{\tau}) = \left( \frac{1}{2} \delta_s^{(\beta_k, \beta_l, 2)}(\bar{\tau}) - \frac{1}{2} \int_{M(\beta_k, 1)(\bar{\tau}) \times M(\beta_l, 1)(\bar{\tau}) \Delta} \left[ \mathbb{P}(\text{Ext}^1(E_1, E_1)) \right] d\mu_m \right)_{\beta_k \neq \beta_l},
\]
\[
\epsilon_i^{(1/2, 1)}(\bar{\tau}) = \tau_i^{(1/2, 1)}(\bar{\tau}) - \frac{1}{2} \int_{M(\beta, 2, 1)(\bar{\tau}) \times M(\beta, 2, 1)(\bar{\tau}) \Delta} \left[ \mathbb{P}(\text{Ext}^1(E_1, E_1)) \right] d\mu_m.
\]
Using the notation in (40), (39) is rewritten as
\[
\tau^{(\beta,2)}(\tilde{\tau}) = \sum_{\beta_k + \beta_l = \beta} \epsilon_1^{(k,l)}(\tilde{\tau}) + \epsilon_2^{(1/2,1/2)}(\tilde{\tau}) + \epsilon_3^{(1/2,1/2)}(\tilde{\tau}) + \sum_{\beta_k + \beta_l = \beta} \epsilon_3^{(k,l)}(\tilde{\tau}) + \epsilon_4^{(1/2,1/2)}(\tilde{\tau}).
\] (41)

Next we show that each summand on the right-hand side of (41) is given by a stack function supported over virtual indecomposables. Note that by construction and Theorem 1, the first summands on the right-hand side of equations (40) are each characteristic stack functions which are given as (stacky) quotients of some associated parameterizing scheme by the action of $GL_2(\mathbb{C})$, together with the corresponding embedding map, in other words,
\[
\tau^{(\beta_k,\beta_l,2)}(\tilde{\tau}) = \left( \left[ \frac{M^{(\beta_k,\beta_l,2)}(\tilde{\tau})}{GL_2(\mathbb{C})} \right], \rho_1 \right).
\]

For more detail on how to obtain the schemes $M^{(\beta_k,\beta_l,2)}(\tilde{\tau})$ look at Appendix 10, Definition 23. Joyce in [9, Section 6.2] has shown that given
\[
\left[ \left( \left[ \frac{U}{GL_2(\mathbb{C})} \right], \nu \right) \right],
\]
one has the following identity of stack functions:
\[
\left[ \left( \left[ \frac{U}{GL_2(\mathbb{C})} \right], \nu \right) \right] = F(GL_2(\mathbb{C}), G_m^2, G_m^2) \left[ \left[ \left[ \frac{U}{G_m^2} \right], \mu \circ i_1 \right] \right] + F(GL_2(\mathbb{C}), G_m^2, G_m^2) \left[ \left[ \left[ \frac{U}{G_m^2} \right], \mu \circ i_2 \right] \right],
\]
where
\[
F(GL_2(\mathbb{C}), G_m^2, G_m^2) = \frac{1}{2}, \quad F(GL_2(\mathbb{C}), G_m^2, G_m^2) = -\frac{3}{4},
\]
and $\mu \circ i_1$ and $\mu \circ i_2$ are the obvious embeddings. Now apply the result of Joyce [9, Section 6.2] and obtain a decomposition of $\tau^{(\beta_k,\beta_l,2)}(\tilde{\tau})$ of the following form:
\[
\tau^{(\beta_k,\beta_l,2)}(\tilde{\tau}) = \left[ \left[ \frac{M^{(\beta_k,\beta_l,2)}(\tilde{\tau})}{G_m^2} \right], \mu' \circ i_1 \right] \right] = \frac{1}{2} \left[ \left[ \frac{M^{(\beta_k,\beta_l,2)}(\tilde{\tau})}{G_m^2} \right], \mu' \circ i_1 \right] - \frac{3}{4} \left[ \left[ \frac{M^{(\beta_k,\beta_l,2)}(\tilde{\tau})}{G_m^2} \right], \mu' \circ i_2 \right],
\] (42)
where $\mu' \circ i_1$ and $\mu' \circ i_2$ are the obvious embeddings.
7.1 Computation of $\Psi^p_\nu(\epsilon^{(k,l)}_1(\bar{\tau}))$

By definition, for any fixed choice of $k,l$, the objects $E_2 \in \mathcal{M}^{(\beta_k, \beta_l, 2)}_1(\bar{\tau})$ fit into non-split exact sequences

$$0 \rightarrow E_1 \rightarrow E_2 \rightarrow E_3 \rightarrow 0,$$

where $E_1 \neq E_3$. In this case, the automorphism group of extension (43) is given by $\mathbb{G}_m$. Since over $\mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau})$ there exists an action of $\text{GL}_2(\mathbb{C})$ and the stabilizer group of each point in $\mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau})$ is $\mathbb{G}_m$, then the $\text{GL}_2(\mathbb{C})$ action reduces to a free action of $\text{PGL}_2(\mathbb{C})$ on $\mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau})$. Hence it is easy to see that there exists a map

$$\pi_1: \mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau})/\text{PGL}_2(\mathbb{C}) \rightarrow \mathcal{M}(\beta_l, 1)(\bar{\tau}) \times \mathcal{M}(\beta_l, 1)(\bar{\tau}) \setminus \Delta$$

which sends $E_2$ to $(E_1, E_3)$.

Consider $(E_1, E_3) \in \mathcal{M}(\beta_l, 1)(\bar{\tau}) \times \mathcal{M}(\beta_l, 1)(\bar{\tau}) \setminus \Delta$. Consider the fiber $\pi_1^{-1}(E_1, E_3)$ which is given by the set of points $E_2 \in \mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau})$ which fit in the exact sequence (43). Dividing by the automorphism group of extension (43), $\mathbb{G}_m$, would provide a bijective correspondence between the set of isomorphism classes of such $E_2$ (which still undergo a free action of $\text{PGL}_2(\mathbb{C})$) and the set of tuples $(E_1, E_3)$. Therefore there exists a bijective map between the closed points of the fiber of $\pi_1$ over $(E_1, E_3) \in \mathcal{M}(\beta_l, 1)(\bar{\tau}) \times \mathcal{M}(\beta_l, 1)(\bar{\tau}) \setminus \Delta$ and the closed points of $\mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau})/\text{PGL}_2(\mathbb{C})$ which fit into (43), i.e. the closed points of $\mathbb{P}(\text{Ext}^1(E_3, E_1))$ over $\mathcal{M}(\beta_l, 1)(\bar{\tau}) \times \mathcal{M}(\beta_l, 1)(\bar{\tau}) \setminus \Delta$. Now rewrite $\mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau})$ as

$$\mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau}) = \mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\bar{\tau})/\text{PGL}_2(\mathbb{C}) \left/ \mathbb{G}_m \right.$$  \( \left. \right. \setminus \Delta \)  \( \left. \right. \setminus \Delta \)

by (44) and (39) the equation for $\epsilon^{(k,l)}_1(\bar{\tau})$ is obtained as

$$\epsilon^{(k,l)}_1(\bar{\tau}) = \int_{\mathcal{M}(\beta_l, 1)(\bar{\tau}) \times \mathcal{M}(\beta_l, 1)(\bar{\tau}) \setminus \Delta} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_3, E_1))}{\mathbb{G}_m} \right] d\mu_m$$

$$= \frac{1}{2} \int_{\mathcal{M}(\beta_l, 1)(\bar{\tau}) \times \mathcal{M}(\beta_l, 1)(\bar{\tau}) \setminus \Delta} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_3, E_1))}{\mathbb{G}_m} \right] d\mu_m$$

$$= \frac{1}{2} \int_{\mathcal{M}(\beta_l, 1)(\bar{\tau}) \times \mathcal{M}(\beta_l, 1)(\bar{\tau}) \setminus \Delta} \left[ \frac{\mathbb{P}(\text{Ext}^1(E_3, E_1))}{\mathbb{G}_m} \right] d\mu_m.$$
Now apply the Lie algebra morphism $\tilde{\Psi}^{B_p}$ to $\epsilon_1^{(k,l)}(\tilde{t})$ and obtain
\[
\tilde{\Psi}^{B_p}(\epsilon_1^{(k,l)}(\tilde{t})) = \frac{1}{2} \chi_{\text{na}} \left( \int \left[ \mu^{*}\nu^{(\beta,2)} \right] d\mu_{m, \mu} \right) \cdot \lambda(\beta,2)
\]
\[
= \frac{1}{2} \chi \left( \text{Spec}(\mathbb{C}) \right) \left[ \frac{\text{Spec}(\mathbb{C})}{\mathbb{G}_m} \right] d\chi \cdot \lambda(\beta,2)
\]
\[
= (-1)^1 \cdot (-1)^{\dim\mathbb{M}(\beta_k,\beta_l)} (\tilde{t}) - 1 \cdot \frac{1}{2} \chi (\text{Spec}(\mathbb{C}) \right) d\chi \cdot \lambda(\beta,2),
\]
where integrals are taken over the points of $\mathbb{M}(\beta_k,\beta_l)$ with respect to the ambient stack. Moreover, the factor of $(-1)^{\dim\mathbb{M}(\beta_k,\beta_l)} (\tilde{t}) - 1$ is due to the fact that a stacky point given as $\text{Spec}(\mathbb{C})/\mathbb{G}_m$ detects a singular point of multiplicity 1.

7.2 Computation of $\tilde{\Psi}^{B_p}(\epsilon_2^{(1/2,1/2)}(\tilde{t}))$

By (42),
\[
\tilde{\Psi}_2^{(\beta/\beta,\beta/\beta)}(\tilde{t}) = \left[ \frac{\mathcal{M}_2^{(\beta/\beta,\beta/\beta)}(\tilde{t})}{\text{GL}_2(\mathbb{C})} \right]
\]
\[
= \frac{1}{2} \left[ \left( \left[ \frac{\mathcal{M}_2^{(\beta/\beta,\beta/\beta)}(\tilde{t})}{\mathbb{G}_m^2} \right], \mu_2^{*}\iota_1 \right) \right]
\]
\[
- \frac{3}{4} \left[ \left( \left[ \frac{\mathcal{M}_2^{(\beta/\beta,\beta/\beta)}(\tilde{t})}{\mathbb{G}_m} \right], \mu_2^{*}\iota_2 \right) \right].
\]

The stabilizer group of points in $\mathcal{M}_2^{(\beta/\beta,\beta/\beta)}(\tilde{t})$ is given by the automorphism group of extensions associated to those points. Since a point $p \in \mathcal{M}_2^{(\beta/\beta,\beta/\beta)}(\tilde{t})(\mathbb{C})$ is represented by an object $E_2$ which fits into a non-split exact sequence
\[
0 \rightarrow E_1 \rightarrow E_2 \rightarrow E_1 \rightarrow 0,
\]
then the automorphism group of extension (46) is given by $\mathbb{A}_1 \times \mathbb{G}_m$. The stabilizer group (at point $p$) of the action of $\text{GL}_2(\mathbb{C})$ on $\mathcal{M}_2^{(\beta/\beta,\beta/\beta)}(\tilde{t})$ is obtained by $\mathbb{A}_1 \times \mathbb{G}_m$. Since $E_1 \cong E_3$ then for diagonal matrices (given by $\mathbb{G}_m^2 = T_{\text{GL}_2(\mathbb{C})}$) we have that
\[
\mathbb{G}_m^2 \cap \text{Stab}_p(\text{GL}_2(\mathbb{C})) = \mathbb{G}_m \subset \mathbb{G}_m^2.
\]
hence the action of $G_m^2$ descends to a free action of $G_m^2/G_m \cong G_m$. Hence
\[
\left[ \left( \frac{M_2^2(\emptyset/\emptyset, \emptyset/\emptyset)}{G_m^2}, \mu'_2 \circ i_1 \right) \right] = \left[ \left( \frac{M_2(\emptyset/\emptyset, \emptyset/\emptyset)}{G_m}, \mu'_2 \circ i_1 \right) \right].
\]

Hence
\[
\delta_2^* (\emptyset/\emptyset, \emptyset/\emptyset)(\emptyset) = \frac{1}{2} \left[ \left( \frac{M_2^2(\emptyset/\emptyset, \emptyset/\emptyset)}{G_m^2}, \mu'_2 \circ i_1 \right) \right]
- \frac{3}{4} \left[ \left( \frac{M_2(\emptyset/\emptyset, \emptyset/\emptyset)}{G_m}, \mu'_2 \circ i_1 \right) \right].
\]
\[\text{(47)}\]

By (39) and (47),
\[
e_2^* (\emptyset/\emptyset, \emptyset/\emptyset)(\emptyset) = \frac{1}{2} \left[ \left( \frac{M_2^2(\emptyset/\emptyset, \emptyset/\emptyset)}{G_m^2}, \mu'_2 \circ i_1 \right) \right]
- \frac{3}{4} \left[ \left( \frac{M_2(\emptyset/\emptyset, \emptyset/\emptyset)}{G_m}, \mu'_2 \circ i_1 \right) \right]
- \frac{1}{2} \int_{M(\emptyset/\emptyset, \emptyset/\emptyset)} \left[ \frac{\mathcal{P}(\text{Ext}^1(E_1, E_1))}{G_m} \right].
\]
\[\text{(48)}\]

7.2.1 Calculation of $\int_{M(\emptyset/\emptyset, \emptyset/\emptyset)} \left[ \frac{\mathcal{P}(\text{Ext}^1(E_1, E_1))}{G_m} \right]$

Note that there exists a map $\rho: M_2^2(\emptyset/\emptyset, \emptyset/\emptyset) \to \Delta \cong M(\emptyset/\emptyset, \emptyset/\emptyset)$ which sends an object $E_2$ fitting in the exact sequence (46) to $E_1$. Moreover, given $E_1 \in M(\emptyset/\emptyset, \emptyset/\emptyset)$, the fiber of $\rho$ over $E_1$ is the set of points $p \in M_2^2(\emptyset/\emptyset, \emptyset/\emptyset)$ represented by the exact sequence (46). Now for any point $E_1 \in M(\emptyset/\emptyset, \emptyset/\emptyset)$ there exists a map $\pi_{\text{Ext}}: \rho^{-1}(\Delta) \to \text{Ext}^1(E_1, E_1)$ which projects the points $p \in \rho^{-1}(E_1)$ to their extension classes. Now consider an element of the extension class $\alpha \in \text{Ext}^1(E_1, E_1) \setminus 0$. The pre-image $\pi_{\text{Ext}}^{-1}(\alpha)$ consists of points $p \in \rho^{-1}(E_1)$ which fall into the class $\alpha$. There exists a surjective morphism
\[
\text{GL}_2(\mathbb{C}) \twoheadrightarrow \pi_{\text{Ext}}^{-1}(\alpha)
\]
which is induced by the $\text{GL}_2(\mathbb{C})$-action on $M_2^2(\emptyset/\emptyset, \emptyset/\emptyset)$. The stabilizer group of the action of $\text{GL}_2(\mathbb{C})$ at the point $p \in M_2^2(\emptyset/\emptyset, \emptyset/\emptyset)$ represented by $E_2$ sitting inside the exact sequence (46) is given by $\mathbb{A}_1 \times G_m$ hence $\text{Stab}(\text{GL}_2(\mathbb{C}))_p$ for $p \in \rho^{-1}(E_1)$ is given by $\mathbb{A}_1 \times G_m$. Now it is easy to relate the virtual Poincaré polynomial of $\pi_{\text{Ext}}^{-1}(\alpha)$ to the virtual Poincaré polynomial of $\text{GL}_2(\mathbb{C})$.

In general, given two algebraic spaces $X$ and $Y$ and a fibration $X \to Y$ with fibers $Z$, one has the following identity for their corresponding virtual Poincaré polynomials:
\[
P_t(X) = P_t(Y) \cdot P_t(Z).
\]
Therefore, we obtain

\[ P_r(GL_2(\mathbb{C})) = P_r(A^1 \times \mathbb{G}_m) \cdot P_r(\pi_{\text{Ext}}^{-1}(\alpha)). \] (49)

On the other hand, for each \( \alpha \) the free action of \( \mathbb{G}_m^2/\mathbb{G}_m \cong \mathbb{G}_m \) on \( M_2^{(\beta/2, \beta/2, 2)}(\tilde{\tau}) \) induces a free \( \mathbb{G}_m \)-action on \( \pi_{\text{Ext}}^{-1}(\alpha) \). Passing to the quotients via this action, we obtain a map

\[ \pi_{\text{Ext}}^{-1}(\alpha) \to \pi_{\text{Ext}}^{-1}(\alpha)/(\mathbb{G}_m^2/\mathbb{G}_m). \]

whose fibers are given by \( \mathbb{G}_m^2/\mathbb{G}_m \cong \mathbb{G}_m \). Hence we obtain the following relation for the virtual Poincaré polynomials:

\[ P_r(\pi_{\text{Ext}}^{-1}(\alpha)) = P_r(\mathbb{G}_m^2/\mathbb{G}_m \cdot P_r(\pi_{\text{Ext}}^{-1}(\alpha)/(\mathbb{G}_m^2/\mathbb{G}_m))). \] (50)

By (49) and (50) and according to calculations in [1, p. 4], we obtain

\[ P_r(\pi_{\text{Ext}}^{-1}(\alpha)/(\mathbb{G}_m^2/\mathbb{G}_m)) = \frac{P_r(GL_2(\mathbb{C}))}{P_r(A^1 \times \mathbb{G}_m) \cdot P_r(\mathbb{G}_m^2/\mathbb{G}_m)} = \frac{(t^4 - 1) \cdot (t^2 - 1) \cdot t^2}{t^2 \cdot (t^2 - 1) \cdot (t^2 - 1)} = t^2 + 1. \] (51)

The computation in (51) means that for each \( E_1 \in M^{(\beta/2, 1)}(\tilde{\tau}) \) by passing to the quotients via the action of \( \mathbb{G}_m^2/\mathbb{G}_m \), the map \( \pi_{\text{Ext}} \) induces a map

\[ \pi_{(\mathbb{G}_m^2/\mathbb{G}_m)}|_{E_1} : \rho^{-1}(E_1)/(\mathbb{G}_m^2/\mathbb{G}_m) \to \mathbb{P}(\text{Ext}^1(E_1, E_1)), \]

whose fibers have virtual Poincaré polynomial as obtained in (51). Moreover, the Euler characteristic of the fibers is computed by evaluating their virtual Poincaré polynomial at \( t = 1 \), hence for every such \( E_1 \) the fiber of the map \( \pi_{(\mathbb{G}_m^2/\mathbb{G}_m)}|_{E_1} \) has the Euler characteristic equal to 2. We will use this factor of 2 in (53) below.

Now go back to (48). Since \( \epsilon_{2}^{(1/2, 1/2)}(\tilde{\tau}) \) is supported over virtual indecomposables, we can apply the Lie algebra homomorphism \( \Psi^{B_p} : \)

\[ \Psi^{B_p}(\epsilon_{2}^{(1/2, 1/2)}(\tilde{\tau})) \]

\[ = \frac{1}{2} \cdot \chi^{m} \left( \frac{[M_2^{(\beta/2, \beta/2, 2)}(\tilde{\tau})/(\mathbb{G}_m^2/\mathbb{G}_m)]}{\mathbb{G}_m} \cdot (\mu_2' \circ i_1')^* \nu_{20}^{(\beta, 2)} \right) \cdot \overline{\chi}(\beta, 2) \]

\[ - \frac{3}{4} \cdot \chi^{m} \left( \frac{[M_2^{(\beta/2, \beta/2, 2)}(\tilde{\tau})]}{\mathbb{G}_m} \cdot (\mu_2' \circ i_2')^* \nu_{20}^{(\beta, 2)} \right) \cdot \overline{\chi}(\beta, 2) \]

\[ - \frac{1}{2} \cdot \chi^{m} \left( \int_{\lambda(\beta/2, 1)} \left[ \mathbb{P}(\text{Ext}^1(E_1, E_1)) \right] \frac{d\mu_m, \mu^* \nu_{20}^{(\beta, 2)}}{[\mathbb{G}_m]} \right) \cdot \overline{\chi}(\beta, 2). \] (52)
Now we compute each term on the right-hand side of (52) separately. For the first term we obtain

$$\frac{1}{2} \cdot \chi^a\left( \left[ \frac{\mathcal{M}_2^{(\beta/2, \beta/2, 2)}(\bar{\tau})}{G_m} \right] \cdot \left( \mu_2 \circ i_1 \right)^* v_{\mathfrak{m}_2^{(\beta, 2)}} \right) \cdot \overline{\lambda}^{(\beta, 2)}$$

$$= (-1)^{\dim \mathfrak{m}_2^{(\beta, 2)}} \cdot \frac{1}{2} \int_{\mathcal{M}_2^{(\beta/2, \beta/2, 2)}(\bar{\tau})/G_m} \left[ \left( \mathfrak{p}(\text{Spec}(C)) \right) \right] \cdot d\bar{\chi} \cdot \overline{\lambda}^{(\beta, 2)}$$

$$= (-1)^{1} \cdot (-1)^{\dim \mathfrak{m}_2^{(\beta, \beta/2, 2)}(\bar{\tau})} \cdot \frac{1}{2} \cdot 2 \int_{\mathcal{M}^{(\beta/2, 2)}(\bar{\tau})} \chi\left( \mathfrak{p}(\text{Ext}^1(E_1, E_1)) \right) \cdot d\bar{\chi} \cdot \overline{\lambda}^{(\beta, 2)}.$$ 

(53)

For the second term on the right-hand side of (52) we use property (b) of the stack functions in (3)

$$\left[ \frac{\mathcal{M}_2^{(\beta/2, \beta/2, 2)}(\bar{\tau})}{G_m} \right] = \chi\left( \mathcal{M}_2^{(\beta/2, \beta/2, 2)}(\bar{\tau}) \right) \cdot \frac{\text{Spec}(C)}{G_m}.$$ 

The action of $G_m \cong \mathbb{G}_m^2/G_m$ is free on $\mathcal{M}_2^{(\beta/2, \beta/2, 2)}(\bar{\tau})$ and since the $G_m$-fixed locus via this action is empty we have that

$$\chi\left( \mathcal{M}_2^{(\beta/2, \beta/2, 2)}(\bar{\tau}) \right) = 0.$$ 

Therefore, the second term on the right-hand side of (52) vanishes

$$-\frac{3}{4} \cdot \chi^a\left( \left[ \frac{\mathcal{M}_2^{(\beta/2, \beta/2, 2)}(\bar{\tau})}{G_m} \right] \cdot \left( \mu_2 \circ i_2 \right)^* v_{\mathfrak{m}_2^{(\beta, 2)}} \right) \cdot \overline{\lambda}^{(\beta, 2)} = 0.$$ 

Finally, by (53) and (52), we obtain

$$\overline{\Psi}_p\left( \epsilon^{(1/2, 1/2)}_2(\bar{\tau}) \right) = -\int_{\mathcal{M}^{(\beta/2, 2)}(\bar{\tau})} \chi\left( \mathfrak{p}(\text{Ext}^1(E_1, E_1)) \right) \cdot d\bar{\chi} \cdot \overline{\lambda}^{(\beta, 2)}$$

$$= -\frac{1}{2} \int_{\mathcal{M}^{(\beta/2, 2)}(\bar{\tau})} \chi\left( \mathfrak{p}(\text{Ext}^1(E_1, E_1)) \right) \cdot d\bar{\chi} \cdot \overline{\lambda}^{(\beta, 2)}$$

$$= -\frac{3}{2} \cdot (-1)^{\dim \mathfrak{m}_2^{(\beta, \beta/2, 2)}(\bar{\tau})} \cdot \frac{1}{2} \int_{\mathcal{M}^{(\beta/2, 2)}(\bar{\tau})} \chi\left( \mathfrak{p}(\text{Ext}^1(E_1, E_1)) \right) \cdot d\bar{\chi} \cdot \overline{\lambda}^{(\beta, 2)}.$$ 

(54)
7.3 Computation of $\tilde{\Psi}_p^{\mathbb{B}^p}(\epsilon_3^{1/2,1/2}(\tilde{\tau}))$

By (39) and (42), we rewrite $\epsilon_3^{1/2,1/2}(\tilde{\tau})$ as follows:

$$\epsilon_3^{1/2,1/2}(\tilde{\tau}) = \frac{1}{2} \left[ \left( \frac{\mathcal{M}_3^{(\beta/2,\beta/2,2)}(\tilde{\tau})}{\mathbb{G}_m^2}, \mu'_3 \circ i_1 \right) \right]$$

$$- \frac{3}{4} \left[ \left( \frac{\mathcal{M}_3^{(\beta/2,\beta/2,2)}(\tilde{\tau})}{\mathbb{G}_m^2}, \mu'_3 \circ i_2 \right) \right]$$

$$- \frac{1}{2} \left[ \frac{\mathcal{M}(\beta/2,1)(\tilde{\tau}) \times \mathcal{M}(\beta/2,1)(\tilde{\tau}) \setminus \Delta}{\mathbb{G}_m^2} \right].$$

The set of $T_{\text{GL}_2}(\mathbb{C})/\mathbb{G}_m$-fixed points is given by the image of the map $f : \mathcal{N}(\beta/2,1)(\tilde{\tau}) \times \mathcal{N}(\beta/2,1)(\tilde{\tau}) \setminus \Delta \to \mathcal{N}_3^{(\beta/2,\beta/2,2)}(\tilde{\tau})$ such that for every $E_1 \neq E_3$ it sends $(E_1, E_3)$ to $E_1 \oplus E_3$. Rewrite

$$\left[ \frac{\mathcal{M}_3^{(\beta/2,\beta/2,2)}(\tilde{\tau})}{\mathbb{G}_m^2} \right] = \left[ \frac{\text{Im}(f)}{\mathbb{G}_m^2} \right] + \left[ \frac{\mathcal{N}_3^{(\beta/2,\beta/2,2)}(\tilde{\tau}) \setminus \text{Im}(f)}{\mathbb{G}_m^2} \right],$$

where (55) is obtained by property (a) of stack functions in (2). Now by injectivity of the map $f$,

$$\left[ \frac{\text{Im}(f)}{\mathbb{G}_m^2} \right] = \left[ \frac{\mathcal{N}(\beta/2,1)(\tilde{\tau}) \times \mathcal{N}(\beta/2,1)(\tilde{\tau}) \setminus \Delta}{\mathbb{G}_m^2} \right],$$

hence

$$\epsilon_3^{1/2,1/2}(\tilde{\tau}) = \frac{1}{2} \left[ \left( \frac{\mathcal{N}(\beta/2,1)(\tilde{\tau}) \times \mathcal{N}(\beta/2,1)(\tilde{\tau}) \setminus \Delta}{\mathbb{G}_m^2}, \mu'_3 \circ i_1 \right) \right]$$

$$+ \frac{1}{2} \left[ \left( \frac{\mathcal{N}_3^{(\beta/2,\beta/2,2)}(\tilde{\tau}) \setminus \text{Im}(f)}{\mathbb{G}_m^2}, \mu'_3 \circ i_1 \right) \right]$$

$$- \frac{3}{4} \left[ \left( \frac{\mathcal{N}_3^{(\beta/2,\beta/2,2)}(\tilde{\tau})}{\mathbb{G}_m^2}, \mu'_3 \circ i_2 \right) \right]$$

$$- \frac{1}{2} \left[ \frac{\mathcal{M}(\beta/2,1)(\tilde{\tau}) \times \mathcal{M}(\beta/2,1)(\tilde{\tau}) \setminus \Delta}{\mathbb{G}_m^2} \right].$$

There exists a free action of $\mathbb{G}_m^2$ on $\mathcal{N}_3^{(\beta/2,\beta/2,2)}(\tilde{\tau})$. Moreover, there exists a trivial action of $\mathbb{G}_m \subset \mathbb{G}_m^2$ on $\mathcal{N}_3^{(\beta/2,\beta/2,2)}(\tilde{\tau})$ where $\mathbb{G}_m$ is given by the corresponding subgroup of diagonal matrices. Hence the free $\mathbb{G}_m^2$ action on $\mathcal{N}_3^{(\beta/2,\beta/2,2)}(\tilde{\tau})$ is reduced.
to a free action of $\mathbb{G}_m^2/\mathbb{G}_m \cong \mathbb{G}_m$. Therefore,
\[
\left[\left(\left[\left(\mathcal{M}_3^{(\beta/2,\beta/2,2)}(\bar{\tau}) \setminus \text{Im}(f)\right) \setminus \mathbb{G}_m^2\right], \mu'_3 \circ i_1\right)\right] = \left[\left(\left(\mathcal{M}_3^{(\beta/2,\beta/2,2)}(\bar{\tau}) \setminus \text{Im}(f)\right) / \mathbb{G}_m^2/\mathbb{G}_m\right), \mu'_3 \circ i_1\right].
\]

Denote\(^5\)
\[A = \mathcal{M}_3^{(\beta/2,\beta/2,2)}(\bar{\tau}) \setminus \text{Im}(f) / \mathbb{G}_m^2/\mathbb{G}_m.\]

With this notation
\[
e_3^{(1/2,1/2)}(\bar{\tau}) = \frac{1}{2} \left[\left(\left[\left[\mathcal{A} / \mathbb{G}_m\right], \mu'_3 \circ i_1\right] \right) - \frac{3}{4} \left[\left(\left[\mathcal{M}_3^{(\beta/2,\beta/2,2)}(\bar{\tau}) / \mathbb{G}_m\right], \mu'_3 \circ i_1\right)\right]\right].
\]

Since $e_3^{(1/2,1/2)}(\bar{\tau})$ is supported over the virtual indecomposables, one can apply the Lie algebra morphism $\tilde{\Psi}_p$,\(^6\)
\[\tilde{\Psi}_p(e_3^{(1/2,1/2)}(\bar{\tau})) = \frac{1}{2} \chi^{\mathcal{A}} \left(\left[\mathcal{M}_3^{(\beta/2,\beta/2,2)}(\bar{\tau}) / \mathbb{G}_m\right], \mu'_3 \circ i_1\right)^* v_{\nu\nu(3)} \tilde{\lambda}(\beta,2) - \frac{3}{4} \chi^{\mathcal{M}_3^{(\beta/2,\beta/2,2)}(\bar{\tau}) / \mathbb{G}_m^2} \mu'_3 \circ i_1\right) v_{\nu\nu(3)} \tilde{\lambda}(\beta,2).
\]

7.3.1 Calculation of $\chi(A)$ and $\chi(M_3^{(\beta/2,\beta/2,2)}(\bar{\tau})$)

There exists a map $\pi_{13}: \mathcal{M}_3^{(\beta/2,\beta/2,2)}(\bar{\tau}) \rightarrow \mathcal{M}(\beta/2,1)(\bar{\tau}) \times \mathcal{M}(\beta/2,1)(\bar{\tau}) \setminus \Delta$ which sends a point $E_2 \cong E_1 \oplus E_3$ to $(E_1, E_3)$. Fix such $(E_1, E_3)$. The set of points in $\pi_{13}^{-1}(E_1, E_3)$ consists of those $E_2$ which can be written as $E_2 \cong E_1 \oplus E_3$. Moreover, every point in $\pi_{13}^{-1}(E_1, E_3) \setminus \text{Im}(f)$ can be determined by $E_2 \cong E_1 \oplus E_3$ or $E_2 \cong E_3 \oplus E_1$, i.e. by a permutation and an isomorphism, hence there exists an induced map
\[\pi'_{13}: \mathcal{M}_3^{(\beta/2,\beta/2,2)}(\bar{\tau}) \rightarrow \text{Sym}(\mathcal{M}(\beta/2,1)(\bar{\tau}) \times \mathcal{M}(\beta/2,1)(\bar{\tau})).\]

The action of $\text{GL}_2(\mathbb{C})$ on $\mathcal{M}_3^{(\beta/2,\beta/2,2)}(\bar{\tau})$ is restricted to an action on the fiber of $\pi'_{13}$ over $(E_1, E_3)$.

The stabilizer group of the points in $(\pi'_{13})^{-1}(E_1, E_3)$ is given by $\mathbb{G}_m^2$. Hence, one concludes that for every $(E_1, E_3) \in \text{Sym}(\mathcal{M}(\beta/2,1)(\bar{\tau}) \times \mathcal{M}(\beta/2,1)(\bar{\tau}))$ there exists a

\(^5\) The scheme $\mathcal{A}$ is an analog of $\overline{Q}_X^{(2,2m)}$ in [18, Lemma 5.6] when the sheaves $F$ composing the objects $E = (F, V, \phi)$ have zero dimensional support with length $2m$. In that situation, roughly speaking, the scheme $\mathcal{M}_3^{(\beta/2,1)}(\bar{\tau})$ is replaced by a subscheme of a product of Quot-schemes. Here we are following an almost identical strategy.
map $GL_2(\mathbb{C}) \to \pi_{13}^{-1}(E_1, E_3)$ whose fiber over each point $p \in (\pi_{13}')^{-1}(E_1, E_3)$ is given by $\mathbb{G}_m^2$. Hence, over $(\pi_{13}')^{-1}(E_1, E_3) \setminus \text{Im}(f)$ the action of $GL_2(\mathbb{C})$ is restricted to $GL_2(\mathbb{C}) \setminus (\mathbb{G}_m^2 \cup (\mathbb{G}_m^2)^*)$, where $\mathbb{G}_m^2$ is given by the diagonal matrices of the form

$$
\mathbb{G}_m^2 = \left\{ \begin{pmatrix} g_1 & 0 \\ 0 & g_2 \end{pmatrix} : g_1, g_2 \in \mathbb{C}^* \right\}.
$$

and $(\mathbb{G}_m^2)^*$ is given by the anti-diagonal matrices of the form

$$
(\mathbb{G}_m^2)^* = \left\{ \begin{pmatrix} 0 & g_1 \\ g_2 & 0 \end{pmatrix} : g_1, g_2 \in \mathbb{C}^* \right\}.
$$

Therefore, there exists a map $GL_2(\mathbb{C}) \setminus (\mathbb{G}_m^2 \cup (\mathbb{G}_m^2)^*) \to (\pi_{13}')^{-1}(E_1, E_3) \setminus \text{Im}(f)$ whose fiber over each point $p \in (\pi_{13}')^{-1}(E_1, E_3) \setminus \text{Im}(f)$ is given by $\mathbb{G}_m^2$. Now compute the virtual Poincaré polynomial of $(\pi_{13}')^{-1}(E_1, E_3) \setminus \text{Im}(f)$:

$$
P_t((\pi_{13}')^{-1}(E_1, E_3) \setminus \text{Im}(f)) = \frac{P_t(GL_2(\mathbb{C}) \setminus (\mathbb{G}_m^2 \cup (\mathbb{G}_m^2)^*)}{P_t(\mathbb{G}_m^2)} \frac{(t^4 - 1)(t^2 - 1)}{(t^2 - 1)^2} = t^4 + t^2 - 1.
$$

The occurrence of the term $(t^2 - 1)^2$ in the numerator is due to the free action of $\mathbb{G}_m^2 \cup (\mathbb{G}_m^2)^*$ on $\text{Im}(f)$. Note that $(\pi_{13}')^{-1}(E_1, E_3) \setminus \text{Im}(f)$ is a $\mathbb{G}_m$ bundle over $(\pi_{13}')^{-1}(E_1, E_3) \setminus \text{Im}(f)/\mathbb{G}_m$, hence

$$
P_t((\pi_{13}')^{-1}(E_1, E_3) \setminus \text{Im}(f)/\mathbb{G}_m) = \frac{P_t((\pi_{13}')^{-1}(E_1, E_3) \setminus \text{Im}(f))}{P_t(\mathbb{G}_m)} = \frac{t^4 + t^2 - 1}{(t^2 - 1)} = t^2 + 2. \quad (57)
$$

Therefore, for every $(E_1, E_3) \in \text{Sym}(\mathcal{M}(\beta/2, 1)(\bar{\tau}) \times \mathcal{M}(\beta/2, 1)(\bar{\tau}))$, by evaluating (57) at $t = 1$, the fibers $(\pi_{13}')^{-1}(E_1, E_3) \setminus \text{Im}(f)$ have the Euler characteristic equal to 3. On the other hand, there exists a bijective map between the set of points in the $\mathbb{G}_m^2/\mathbb{G}_m$-fixed locus of $\mathcal{M}(\beta/2, \beta/2, 2)(\bar{\tau})$ and the set of points in $\text{Im}(f) \cong \mathcal{M}(\beta/2, 1)(\bar{\tau}) \times \mathcal{M}(\beta/2, 1)(\bar{\tau}) \setminus \Delta$. Denote by $d_3 = \dim \mathcal{M}(\beta, \beta, 3)(\bar{\tau}) - 1$. Now rewrite
Throughout this subsection by earlier construction $\beta_k \neq \beta_1$ and $\beta_k + \beta_1 = \beta$. The action of $GL_2(\mathbb{C})$ restricts to an action of $G_2^m$ on $M^3(\beta_k, \beta_l, 2)$ hence we obtain

$$\overline{\Psi}^BP(\epsilon^{(1/2,1/2)}_3(\tilde{t})) = \left( (-1)^1 \cdot \chi(A) - (-1)^1 \cdot \frac{3}{4} \cdot \chi(M^3(\beta_k, \beta_l, 2, 2)(\tilde{t})) \right) \cdot (-1)^{d_3} \cdot \overline{\chi}(\beta, 2)$$

$$= \left( -\frac{1}{2} \int_A \chi(A) + \frac{3}{4} \int M^3(\beta_k, \beta_l, 2, 2)(\tilde{t}) \cdot (-1)^{d_3} \cdot \overline{\chi}(\beta, 2) \right)$$

$$= \frac{3}{2} \int \chi(\cdot) \cdot (-1)^{d_3} \cdot \overline{\chi}(\beta, 2) + \frac{3}{4} \int M^3(\tilde{t}) \cdot (-1)^{d_3} \cdot \overline{\chi}(\beta, 2)$$

$$= 0,$$

where $\cdot$ stands for $\text{Sym}(M^3(\beta_k, \beta_l, 2)(\tilde{t}) \times M^3(\beta_k, \beta_l, 2)(\tilde{t}))$.

### 7.4 Computation of $\overline{\Psi}^BP(\epsilon^{(k,l)}_3(\tilde{t}))$

Throughout this subsection by earlier construction $\beta_k \neq \beta_l$ and $\beta_k + \beta_l = \beta$. The action of $GL_2(\mathbb{C})$ restricts to an action of $G_2^m$ on $M^3(\beta_k, \beta_l, 2)$ hence we obtain

$$\overline{\chi}(\beta_k, \beta_l)(\tilde{t}) = \left[ M^3(\beta_k, \beta_l, 2)(\tilde{t}) \right] \cdot 2d_2$$

On the other hand, it is easily seen that there exists a bijective map $f : M^3(\beta_k, \beta_l, 2)(\tilde{t}) \rightarrow M^3(\beta_k, \beta_l, 2)(\tilde{t}) \times M^3(\beta_k, \beta_l, 2)(\tilde{t})$ which takes $E_2 \equiv E_1 \oplus E_3$ to $(E_1, E_3)$ where $E_1 \neq E_3$. Hence, we obtain

$$\left[ M^3(\beta_k, \beta_l, 2)(\tilde{t}) \right] \cdot 2d_2 = \left[ M^3(\beta_k, \beta_l, 2)(\tilde{t}) \times M^3(\beta_k, \beta_l, 2)(\tilde{t}) \right].$$

Therefore, for every pair $(\beta_k, \beta_l)$ by definition of $\epsilon^{(k,l)}_3(\tilde{t})$ one obtains

$$\epsilon^{(k,l)}_3(\tilde{t}) = \frac{1}{2} \left( \left[ M^3(\beta_k, \beta_l, 2)(\tilde{t}) \right] \cdot 2d_2 - \left[ M^3(\beta_k, \beta_l, 2)(\tilde{t}) \times M^3(\beta_k, \beta_l, 2)(\tilde{t}) \right] \right) = 0,$$

hence

$$\sum_{\beta_k + \beta_l = \beta} \overline{\Psi}^BP(\epsilon^{(k,l)}_3(\tilde{t})) = 0.$$
7.5 Computation of $\tilde{\Psi}_p^{\beta}(\epsilon_4^{(1/2,1/2)}(\tilde{\tau}))$

By construction, there exists a bijective map between $N_4(\beta,\beta/2,2,2)(\tilde{\tau})$ and $N_4(\beta/2,2,1,1)(\tilde{\tau})$, hence one rewrites $\epsilon_4^{(1/2,1/2)}(\tilde{\tau})$ directly as follows:

$$
\epsilon_4^{(1/2,1/2)}(\tilde{\tau}) = \frac{1}{2} \left[ \left( \frac{M_{\beta}^{(\beta/2,2,2,2)}(\tilde{\tau})}{G_m^2} \right) \cdot \mu' \circ i_1 \right] 
- \frac{3}{4} \left[ \left( \frac{M_{\beta}^{(\beta/2,2,2,2)}(\tilde{\tau})}{G_m} \right) \cdot \mu_2 \circ i_2 \right] 
- \frac{1}{2} \left[ \left( \frac{M_{\beta}^{(\beta/2)}(\tilde{\tau})}{G_m^2} \right) \cdot \mu' \right] 
- \frac{1}{2} \left[ \left( \frac{M_{\beta}^{(\beta/2)}(\tilde{\tau})}{G_m} \right) \cdot \mu \right] 
+ \frac{1}{2} \left[ \left( \frac{M_{\beta}^{(\beta,1)}(\tilde{\tau})}{G_m^2} \right) \cdot \mu' \circ i_1 \right] 
- \frac{3}{4} \left[ \left( \frac{M_{\beta}^{(\beta,1)}(\tilde{\tau})}{G_m} \right) \cdot \mu_2 \circ i_2 \right] 
$$

which simplifies to

$$
\epsilon_4^{(1/2,1/2)}(\tilde{\tau}) = -\frac{1}{4} \left[ \left( \frac{M_{\beta}^{(\beta,1)}(\tilde{\tau})}{G_m^2} \right) \cdot \mu' \circ i_2 \right].
$$

Now apply the Lie algebra homomorphism and obtain

$$
\tilde{\Psi}_p^{\beta}(\epsilon_4^{(1/2,1/2)}(\tilde{\tau})) = -\frac{1}{4} \cdot \chi^{(\beta)} \left[ \left( \frac{M_{\beta}^{(\beta,1)}(\tilde{\tau})}{G_m^2} \right), (\mu' \circ i_2) \cdot \nu_{\beta}^{(\beta,2)} \right] \cdot \tilde{\chi}^{(\beta,2)}
= (-1)^{\gamma} \cdot (\gamma) \cdot \chi^{(\beta,1)}(\tilde{\tau}) \cdot \chi^{(\beta,2)}.
$$

8 Computation of $\tilde{\Psi}_p^{\beta}(\tau^{(\beta,2)}(\tilde{\tau}))$

Finally in order to compute $\tilde{\Psi}_p^{\beta}(\tau^{(\beta,2)}(\tilde{\tau}))$ in (41), we add the contributions coming from $\epsilon_i^{(k,l)}$ (for all possible choices of $\beta_i$ and $\beta_j$) to $\tilde{\Psi}_p^{\beta}(\tau^{(\beta,2)}(\tilde{\tau}))$, i.e.

$$
\tilde{\Psi}_p^{\beta}(\tau^{(\beta,2)}(\tilde{\tau})) = \sum_{\beta_k + \beta_l = \beta}^0 \tilde{\Psi}_p^{\beta}(\epsilon_1^{(k,l)}(\tilde{\tau})) 
+ \tilde{\Psi}_p^{\beta}(\epsilon_2^{(1/2,1/2)}(\tilde{\tau})) + \tilde{\Psi}_p^{\beta}(\epsilon_3^{(1/2,1/2)}(\tilde{\tau})) 
+ \sum_{\beta_k + \beta_l = \beta}^0 \tilde{\Psi}_p^{\beta}(\epsilon_3^{(k,l)}(\tilde{\tau})) + \tilde{\Psi}_p^{\beta}(\epsilon_4^{(1/2,1/2)}(\tilde{\tau})).
$$
Let $d_i = \dim \mathcal{M}_{i}^{(\beta_k, \beta_1, 3)}(\tilde{t}) - 1$ for $i = 1, \ldots, 4$. By (45), (54), (58), (59) we obtain

$$
\widetilde{\Psi}^{B_\beta}(\mathbf{z}(\beta, 2)) = x^a \left( \frac{\mathcal{X}^{a}(\beta, 2)}{\text{GL}_2(\mathbb{C})} \cdot v_{20(\beta, 2)} \right) \cdot \bar{\chi}(\beta, 2) + \sum^{0}_{\beta_k + \beta_i = \beta} \left( -\frac{1}{2} \right) (-1)^{d_1} \int \mathcal{X}(\mathbb{P}(\text{Ext}^1(E_3, E_1))) \, d\chi \cdot \bar{\chi}(\beta, 2)
$$

$$
+ \frac{3}{2} (-1)^{d_2+1} \int \mathcal{X}(\mathbb{P}(\text{Ext}^1(E_1, E_1))) \, d\chi \cdot \bar{\chi}(\beta, 2)
$$

$$
+ \frac{1}{4} (-1)^{d_4} \sum_{1 \leq i \leq 4} \frac{(-1)^{d_3}}{i!} \mathcal{X}_{2}\mathcal{B}_\beta\mathcal{P}(0, 2, (\beta_i, 0)) \cdot \bar{\chi}(\beta, 2),
$$

(60)

where $\ast$ stands for $\mathcal{M}^{(\beta_k, -1)}(\tilde{t}) \times \mathcal{M}(\beta, 1)(\tilde{t}) \setminus \Delta$.

9 Final computation of invariants

By the wall crossing computation of Joyce and Song in [10, Equation (13.31)],

$$
\chi\left(\mathcal{M}^{(\beta_k, 2)}_{(\beta, 2)}(\tilde{t})\right) = \sum_{1 \leq l \leq L} \frac{(1)}{l!} \mathcal{X}_{2}\mathcal{B}_\beta\mathcal{P}(0, 2, (\beta_1, 0)) \cdot \prod_{i=1}^{l} \left( \frac{\mathcal{D}^\beta}{\mathcal{D}^\beta_1 (\tau)} \cdot \bar{\chi}_{2}\mathcal{B}_\beta\mathcal{P}(0, 2, (\beta_1 + \cdots + \beta_{i-1}, 0)) \cdot (-1)^{\mathcal{X}_{2}\mathcal{B}_\beta\mathcal{P}(0, 2, (\beta_1, 0)) + \sum_{i=1}^{l} \mathcal{X}_{2}\mathcal{B}_\beta\mathcal{P}(0, 2, (\beta_1 + \cdots + \beta_{i-1}, 2, (\beta_i, 0))) \right).
$$

(61)

By Definition 16, (61) and (60), we obtain

$$
\mathcal{B}_\beta^\mathcal{N}(X, \beta, 2, \tilde{t}) = \sum_{\beta_k + \beta_i = \beta} (-1)^{d_1+1} \frac{1}{2} \int \mathcal{X}(\mathbb{P}(\text{Ext}^1(E_3, E_1))) \, d\chi
$$

$$
+ \frac{3}{2} (-1)^{d_2+1} \int \mathcal{X}(\mathbb{P}(\text{Ext}^1(E_1, E_1))) \, d\chi
$$

$$
+ \frac{1}{4} (-1)^{d_4} \sum_{1 \leq i \leq 4} \frac{(-1)^{d_3}}{i!} \mathcal{X}_{2}\mathcal{B}_\beta\mathcal{P}(0, 2, (\beta_i, 0)) \cdot \bar{\chi}(\beta, 2)
$$

(62)

where the first and second summands on the right-hand side of (62) can be calculated easily based on the geometry given and using Grothendieck–Riemann–Roch along the fibers.
Remark 6 It is easy to see that by substituting \([\mathbb{P}^1], 2\) in (62) one immediately obtains the result obtained in (22). As another example one may try to compute the right-hand side of (62) by substituting \((\beta, 2) = (2[\mathbb{P}^1], 2)\), for instance when the base variety \(X\) is given by the total space of \(\mathcal{O}_{\mathbb{P}^1}(-1) \rightarrow \mathbb{P}^1\). Assume \(\chi(F) = k\). Now, if \(k = 2q + 1\) then semistability implies stability and if \(k = 2q\) then \(F\) is given as a strictly semistable sheaf. Based on computations in [5, 11] for \(k = 2q + 1\) there exist no stable sheaves with \(\beta = 2[\mathbb{P}^1]\). Now assume \(k = 2q\). In this case the semistable sheaves are given by \(F = \mathcal{O}_{\mathbb{P}^1}(q - 1) \oplus \mathcal{O}_{\mathbb{P}^1}(q - 1)\).\(^6\) Therefore by substituting \((2[\mathbb{P}^1], 2)\) in (62) we see that

\[
B_p^p(X, 2[\mathbb{P}^1], 2, \tilde{\tau}) = -\frac{1}{2} (n + q)^2 - (n + q).
\]

The computations in this case involve arguments similar to the ones given in Sect. 3 hence we have omitted the explicit calculations here.

Remark 7 In [18], Toda has exploited similar stratification strategy for the moduli stack of objects composed of a zero dimensional sheaf \(F\) given as the quotient \(\mathcal{O}_X \twoheadrightarrow F\), where the objects are assumed to be semistable with respect to a stability condition in the sense of Bridgeland [2]. Moreover the author has given an evidence of the integrality conjecture [12, Conjecture 6] for the corresponding partition functions associated to the moduli stack of these objects. The identities in [18, (88), (99) and (100)] play an important role in the author’s proof of the integrality conjecture. Our stratification strategy and calculation of the invariants share many similarities with those in [18]. Equations (45) and (54) are analogs of equations (88) and (99) in [18] respectively, and we suspect that in some cases they can be used to prove the integrality property of the corresponding partition functions for the invariants of the moduli stack of objects in \(\mathcal{B}_p\). Note that the stability condition used in our approach is the weak stability condition (Definition 6) used by Joyce–Song in [10] which, despite having a much simpler definition than the Bridgeland stability conditions used by Toda in [18], shares many strong properties with them.

10 Appendix: Locally closedness of the strata

In this appendix we discuss the reason behind the assumption on locally closedness property of the strata obtained on the right-hand side of (26). As was mentioned in Theorem 1, the moduli stack of semistable objects in \(\mathcal{B}_p\) is obtained as a two-fold (stacky) quotient (by \(\text{GL}_r(\mathbb{C}) \times \text{GL}(V)\)) of the bundle \(p^{\mathbb{B}r}\), parameterizing the maps \(\mathcal{O}_X(-n) \rightarrow F\), defined over the Quot-scheme, parameterizing \(F\). Our strategy in this section is to investigate the locally closedness property of the strata appearing on the right-hand side of (26), via analyzing the stabilizer groups of objects in their corresponding parameterizing schemes, given as subschemes of \(p^{\mathbb{B}r}\).

\(^6\) Note that by obvious reasons, a sheaf \(F = \mathcal{O}_{\mathbb{P}^1}(a) \oplus \mathcal{O}_{\mathbb{P}^1}(b)\) where \(a \neq b\) is unstable.
Lemma 6 Fix \((\beta_k, \beta_l)\) such that \(\beta_k + \beta_l = \beta\), then the \((k, l)\)-th summand on the right-hand side of (27) is composed of locally closed strata.

Proof By Theorem 1, there exists a projection map
\[
\mathcal{P}^2 \xrightarrow{\pi} \mathfrak{M}(\beta, 2).
\]
Let us use the notation for the underlying parametrizing scheme
\[
\mathfrak{S}^{(\beta, 2)}_{st, ss}(\tilde{t}) = \pi^{-1}(\mathfrak{M}(\beta, 2)) \subset \mathcal{P}^2.
\]
By construction in Sect. 1.2 and Remark 5, there exists an action of \(\text{GL}_2(\mathbb{C}) \times \text{GL}(V)\) on \(\mathfrak{S}^{(\beta, 2)}_{st, ss}(\tilde{t})\). This action induces an action of the corresponding Lie algebra on the tangent space of \(\mathfrak{S}^{(\beta, 2)}_{st, ss}(\tilde{t})\) given by the map
\[
\mathcal{O}_{\mathfrak{S}^{(\beta, 2)}_{st, ss}(\tilde{t})} \otimes (\mathfrak{gl}_2(\mathbb{C}) \times \mathfrak{gl}(V)) \rightarrow T_{\mathfrak{S}^{(\beta, 2)}_{st, ss}(\tilde{t})}.
\]
The dimension of the automorphism group of objects representing the elements of \(\mathfrak{S}^{(\beta, 2)}_{st, ss}(\tilde{t})\) is given by the dimension of their stabilizer group (in \(\text{GL}_2(\mathbb{C}) \times \text{GL}(V)\)), which is given by the dimension of the kernel of the map in (63), which itself is an upper-semi continuous function. Now let us denote the \((k, l)\)-th summand on the right-hand side of (27) by
\[
R = \mathfrak{M}^{(\beta_k, \beta_l, 2)}(\tilde{t}) \cup \mathfrak{M}^{(\beta_k, \beta_l, 2)}(\tilde{t}) \cup \mathfrak{M}^{(\beta_k, \beta_l, 2)}(\tilde{t}) \cup \mathfrak{D}^{(\beta_k, \beta_l, 2)}(\tilde{t}).
\]
Then take the pre-image of \(R\) under \(\pi\) and denote
\[
\pi^{-1}R = \mathfrak{S}^{(\beta_k, \beta_l, 2)}_{1}(\tilde{t}) \cup \mathfrak{S}^{(\beta_k, \beta_l, 2)}_{2}(\tilde{t}) \cup \mathfrak{S}^{(\beta_k, \beta_l, 2)}_{0,\Delta}(\tilde{t}) \cup \mathfrak{S}^{(\beta_k, \beta_l, 2)}_{\Delta}(\tilde{t}) \subset \mathfrak{S}^{(\beta, 2)}_{st, ss}(\tilde{t})
\]
and observe that the dimension of the stabilizer group of points in each summand of \(\pi^{-1}R\) remains constant as we vary over points inside that stratum.

Now we would like to re-package the data on the right-hand side of (65) and write \(\pi^{-1}R\) as a sum of three summands, based on the dimension of stabilizer groups involved. First note that the stabilizer group of points in \(\mathfrak{S}^{(\beta_k, \beta_l, 2)}_{1}(\tilde{t})\) is given by the automorphism group of their corresponding objects (i.e. given by extensions of stable non-isomorphic objects with classes \((\beta_k, 1)\) and \((\beta_l, 1)\)) which is given by \(\mathbb{C}^*_m\) (Lemma 5). So let us denote this stratum (with one dimensional stabilizer group) as \(R^*_1 = \mathfrak{S}^{(\beta_k, \beta_l, 2)}_{1}(\tilde{t})\). Now for the second and third summands, notice that the stabilizer groups of elements in \(\mathfrak{S}^{(\beta_k, \beta_l, 2)}_{2}(\tilde{t})\) and \(\mathfrak{S}^{(\beta_k, \beta_l, 2)}_{0,\Delta}(\tilde{t})\) are given by \(\mathbb{A}_1 \times \mathbb{C}^*_m\) and \(\mathbb{C}^*_m\) respectively. Therefore, let us denote the union of these two strata (both of which have 2-dimensional stabilizer groups) as
\[
R^*_2 = \mathfrak{S}^{(\beta_k, \beta_l, 2)}_{2}(\tilde{t}) \cup \mathfrak{S}^{(\beta_k, \beta_l, 2)}_{0,\Delta}(\tilde{t})
\]
Finally by construction, the stabilizer group of elements in \(\mathfrak{D}^{(\beta_k, \beta_l, 2)}(\tilde{t})\) is given by \(\mathbb{A}_1 \times \mathbb{C}^*_m\) and so let
\[
R^*_3 = \mathfrak{D}^{(\beta_k, \beta_l, 2)}(\tilde{t})
\]
Hence, the right-hand side of (64) is written as
\[ \pi^{-1} R = R'_1 \cup R'_2 \cup R'_3, \]
where the points over \( R'_1, R'_2, \) and \( R'_3 \) have 1-, 2- and 3-dimensional stabilizer groups respectively. It is true that \( R'_1, R'_2, \) and \( R'_3 \) are locally closed in \( \mathfrak{S}^{(\beta,2)} \) (defined in Lemma 3).

Now let us discuss the locally closedness property of these strata. First, consider \( R'_2 \). Let \( \overline{\mathfrak{S}^{(\beta_k,\beta_l,2)}_{O,\Delta}}(\tilde{\tau}) \) denote the closure of \( \mathfrak{S}^{(\beta_k,\beta_l,2)}_{O,\Delta}(\tilde{\tau}) \) in \( \mathfrak{S}^{(\beta,2)}_{ss} \). Recall that by definition, the objects parametrized by elements of \( \mathfrak{S}^{(\beta_k,\beta_l,2)}_{O,\Delta}(\tilde{\tau}) \) are given by split extensions, i.e. \( E_2 \cong E_1 \oplus E_3 \) where \( E_1 \neq E_3 \). The automorphism group of these objects is given by \( \mathbb{G}_m \). Taking the closure of \( \overline{\mathfrak{S}^{(\beta_k,\beta_l,2)}_{O,\Delta}}(\tilde{\tau}) \), we immediately see that the objects parametrized by \( \overline{\mathfrak{S}^{(\beta_k,\beta_l,2)}_{O,\Delta}}(\tilde{\tau}) \) are given by all split extensions of \( E_1 \) by \( E_3 \), i.e. one has
\[ \overline{\mathfrak{S}^{(\beta_k,\beta_l,2)}_{O,\Delta}}(\tilde{\tau}) \subset \mathfrak{S}^{(\beta_k,\beta_l,2)}_{O,\Delta}(\tilde{\tau}) \cup R'_3. \]

Now take the closure of \( \mathfrak{S}^{(\beta_k,\beta_l,2)}_2(\tilde{\tau}) \) and obtain \( \overline{\mathfrak{S}^{(\beta_k,\beta_l,2)}_2(\tilde{\tau})} \). By definition, the objects representing elements of \( \mathfrak{S}^{(\beta_k,\beta_l,2)}_2(\tilde{\tau}) \) are given by non-split exact sequences
\[ 0 \to E_1 \to E_2 \to E_3 \to 0, \]
where \( E_1 \cong E_3 \). So it is seen that taking the closure, the objects representing the elements in the boundary of \( \overline{\mathfrak{S}^{(\beta_k,\beta_l,2)}_2(\tilde{\tau})} \) are given by \( E_2 \cong E_1 \oplus E_3 \) where \( E_1 \cong E_3 \), i.e.
\[ \overline{\mathfrak{S}^{(\beta_k,\beta_l,2)}_2(\tilde{\tau})} \subset \mathfrak{S}^{(\beta_k,\beta_l,2)}_2(\tilde{\tau}) \cup R'_3. \]

Since \( R'_3 \cap \mathfrak{S}^{(\beta_k,\beta_l,2)}_{O,\Delta}(\tilde{\tau}) = \emptyset \) and \( R'_3 \cap \mathfrak{S}^{(\beta_k,\beta_l,2)}_2(\tilde{\tau}) = \emptyset \), then it is seen that \( \mathfrak{S}^{(\beta_k,\beta_l,2)}_{O,\Delta}(\tilde{\tau}) \) and \( \mathfrak{S}^{(\beta_k,\beta_l,2)}_2(\tilde{\tau}) \) have empty intersections in \( R'_3 \), but non-empty intersections in \( R'_3 \), in other words, their boundary is given by a subset of \( R'_3 \) which itself is locally closed in \( \mathfrak{S}^{(\beta,2)}_{ss} \). Hence \( \mathfrak{S}^{(\beta_k,\beta_l,2)}_{O,\Delta}(\tilde{\tau}) \) and \( \mathfrak{S}^{(\beta_k,\beta_l,2)}_2(\tilde{\tau}) \) are locally closed in \( \mathfrak{S}^{(\beta,2)}_{ss} \).

Remark 8 Here, for completeness, we discuss a second approach to the proof of the fact that \( \mathfrak{S}^{(\beta_k,\beta_l,2)}_2(\tilde{\tau}) \) and \( \mathfrak{S}^{(\beta_k,\beta_l,2)}_{O,\Delta}(\tilde{\tau}) \) are locally closed in \( R'_2 \).

Proof First we state a theorem from SGA3 [19, Exposé X, Theorem 8.8] :

Let \( \mathcal{T} \) be a commutative flat group scheme, separated of finite type over a noetherian scheme \( S \), with connected affine fibers. Let \( s \in S \) and \( \mathfrak{s} \) be a geometric point over \( s \) and suppose:

- the reduced subscheme \((\mathcal{T}_s)_{red}\) of the geometric fiber \( \mathcal{T}_s \) is a torus, and
- there exists a generalization \( t \) of \( s \) (i.e. the closure of \([t]\) contains \( s \)) such that \( \mathcal{T}_t \) is smooth over \( k(t) \), the residue field of \( t \).
Then there exists an open neighborhood $U$ of $s$ such that $T|_U$ is a torus over $U$.

Note that, by construction, $R'_2$ is given as a stratum of $S^{(p, 2)}_{\text{st-ss}}$ over which the stabilizer groups of associated points are two dimensional. As we vary over $R'_2$, the stabilizer groups of points in $R'_2$ make a group scheme $\mathcal{G}$ over $\mathbb{C}$. According to the above theorem, for every point $p \in R'_2$ such that $(\mathcal{G}_p)_{\text{red}}$ is given by the two dimensional torus $(\mathbb{G}_m^2)$, there exists an open neighborhood $U$ such that $S|_U$ is given by $\mathbb{G}_m^2$. Let $\mathcal{K}$ denote the union of all such $U$. It is easily seen that every geometric point $k \in \mathcal{K}$ is given as a two dimensional torus $\mathbb{G}_m^2$ which corresponds to the stabilizer group of a point $p \in S^{(p, 2)}_{\text{st-ss}}$ with torus stabilizers, i.e. $S^{(p, 2)}_{\text{st-ss}}(\tilde{\tau})$ is open in $R'_2$. Since $R'_2$ is locally closed in $S^{(p, 2)}_{\text{st-ss}}$ then $S^{(p, 2)}_{\text{st-ss}}(\tilde{\tau})$ is locally closed in $S^{(p, 2)}$. On the other hand, the complement $(S^{(p, 2)}_{\text{st-ss}}(\tilde{\tau}))^c$ is closed in $R'_2$. Since $S^{(p, 2)}_{\text{st-ss}}(\tilde{\tau}) \cap S^{(p, 2)}_{\text{st-ss}}(\tilde{\tau}) = \emptyset$ then $S^{(p, 2)}_{\text{st-ss}}(\tilde{\tau}) \subset (S^{(p, 2)}_{\text{st-ss}}(\tilde{\tau}))^c$ which is closed in $R'_2$, hence $S^{(p, 2)}_{\text{st-ss}}(\tilde{\tau})$ is locally closed in $S^{(p, 2)}_{\text{st-ss}}$. 

Now consider the $(k, l)$-th summand on the right-hand side of (27). The action of \(GL(V)\) on $S^{(p, 2)}_{\text{st-ss}}$ induces an action on each stratum. Take the quotient of each stratum by \(GL(V)\) and obtain locally closed quotient stacks (disjoint from one another) as follows.

**Definition 23** Define

\[
\mathcal{M}^{(p, 2)}_{1}(\tilde{\tau}) \leftarrow \left[ \frac{S^{(p, 2)}_{\text{st-ss}}(\tilde{\tau})}{\text{GL}(V)} \right], \quad \mathcal{M}^{(p, 2)}_{2}(\tilde{\tau}) \leftarrow \left[ \frac{S^{(p, 2)}_{\text{st-ss}}(\tilde{\tau})}{\text{GL}(V)} \right].
\]

**Definition 24** Define

\[
\mathcal{M}^{(p, 2)}_{\text{st-ss}}(\tilde{\tau}) \leftarrow \left[ \frac{S^{(p, 2)}_{\text{st-ss}}(\tilde{\tau})}{\text{GL}(V)} \right].
\]

By Definitions 23 and 24 and (27), one obtains

\[
\mathcal{M}^{(p, 2)}_{\text{st-ss}}(\tilde{\tau}) = \bigcup_{\beta_k + \beta_l = \beta} \left( \mathcal{M}^{(p, 2)}_{1}(\tilde{\tau}) \cup \mathcal{M}^{(p, 2)}_{2}(\tilde{\tau}) \right) \bigcup_{\beta_k + \beta_l = \beta} \left( \mathcal{M}^{(p, 2)}_{\text{st-ss}}(\tilde{\tau}) \cup \mathcal{M}^{(p, 2)}_{\text{st-ss}}(\tilde{\tau}) \right).
\]

Now by our construction taking the quotient of $\mathcal{M}^{(p, 2)}_{\text{st-ss}}(\tilde{\tau})$ one more time by the action of $GL_2(\mathbb{C})$ will naturally produce back the quotient stack $\mathcal{M}^{(p, 2)}_{\text{st-ss}}(\tilde{\tau})$ and the right-
hand side of (27), in other words, we can easily see that

$$\mathcal{M}_1^{(\beta_k, \beta_l, 2)}(\bar{t}) = \frac{\mathcal{L}_1^{(\beta_k, \beta_l, 2)}(\bar{t})}{\text{GL}_2(\mathbb{C})}, \quad \mathcal{M}_2^{(\beta_k, \beta_l, 2)}(\bar{t}) = \frac{\mathcal{L}_2^{(\beta_k, \beta_l, 2)}(\bar{t})}{\text{GL}_2(\mathbb{C})},$$

$$\mathcal{M}_0^{(\Delta, \beta_l, 2)}(\bar{t}) = \frac{\mathcal{L}_0^{(\Delta, \beta_l, 2)}(\bar{t})}{\text{GL}_2(\mathbb{C})}, \quad \mathcal{D}^{(\beta_k, \beta_l, 2)}(\bar{t}) = \frac{\mathcal{D}^{(\beta_k, \beta_l, 2)}(\bar{t})}{\text{GL}_2(\mathbb{C})}.$$  

Acknowledgements I would like to thank Sheldon Katz for suggesting the computation in Sect. 3. Thanks to Yukinobu Toda for many valuable discussions and for explaining to me his paper on rank 2 Donaldson–Thomas invariants. Thanks to Arend Bayer for kindly answering some of my questions related to this work in spring 2011. I am grateful to Richard Thomas for his help and support and for providing me the opportunity for being a member at the Isaac Newton Institute for Mathematical Sciences during 2010–2011. I also thank the Newton Institute for hospitality. I acknowledge partial support from NSF grants DMS 0244412, DMS 0555678 and DMS 08–38434 EMSW21–MCTP (R.E.G.S) during the time that the first drafts of project were being completed. I would also like to thank Kavli IPMU and MIT for their kind and wonderful hospitality. My work at IPMU was supported by the World Premier International Research Center Initiative (WPI Initiative), MEXT, Japan.
