A CUSP SLOPE-CENTRAL ANISOTROPY THEOREM

JIN H. AN1 2 AND N. WYN EVANS3

SUBMITTED TO THE ASTRONOMICAL JOURNAL

ABSTRACT

For a wide class of self-gravitating systems, we show that if the density is cusped like $r^{-\gamma}$ near the center, then the limiting value of the anisotropy parameter $\beta = 1 - \langle v_r^2 \rangle / (2 \langle v_t^2 \rangle)$ at the center may not be greater than $\gamma/2$. Here, $\langle v_r^2 \rangle$ and $\langle v_t^2 \rangle$ are the radial and tangential velocity second moments. This follows from the non-negativity of the phase space density. We compare this theorem to other proposed relations between the cusp slope and the central anisotropy to clarify their applicabilities and underlying assumptions. The extension of this theorem to tracer populations in an externally imposed potential is also derived. In particular, for stars moving in the vicinity of a central black hole, this reduces to $\gamma \geq \beta + 1/2$, indicating that an isotropic system in Keplerian potential should be cusped at least as steep as $r^{-1/2}$. Similar limits have been noticed before for specific forms of the distribution function, but here we establish this as a general result.

Subject headings: stellar dynamics — methods: analytical — galaxies: kinematics and dynamics

1. INTRODUCTION

Numerical simulations of halo formation provide strong evidence that the inner parts of dark matter halos are strongly cusped. Typically, the density profile $\rho$ behaves like $r^{-\gamma}$ where $\gamma$ lies between 1 and 1.5. Navarro, Frenk, & White (1995), Moore et al. (1998) claimed that the density profile $\rho$ behaves like $r^{-\gamma}$ where $\gamma$ lies between 1 and 1.5. Although this numerical result seems well-established, observational evidence that dark halos are cusped has been surprisingly elusive. A disparate body of data — including the rotation curves of dwarf spirals (Palunas & Williams, 2000; de Blok et al., 2011), the kinematics of Local Group dwarf spheroidals (Kleva et al., 2003) and mass models of gravitational lens systems (Tyzon, Kochanski, and dell’Antonio, 1998) — seem to favor constant density cores.

Recently, Hansen (2004) claimed that the only density slopes permitted by the spherically symmetric and isotropic Jeans equations are 1 $\leq \gamma \leq 3$ if the phase-space density-like quantity, $\rho/(\langle v_r^3 \rangle)_{1/2}$ follows a power-law (Taylor & Navarro, 2001). This result was inferred from the condition that the power-law solution of the Jeans and Poisson equations is physical, subject to the ‘equation of state’ (EoS), $\rho \propto r^{-\gamma}(\langle v_r^2 \rangle)$ where $p$ and $c$ are constants. He further argued that, for the system with an anisotropic velocity dispersion tensor, $1 + \beta \leq \gamma \leq 3$. Here, the anisotropy parameter is $\beta = 1 - \langle v_r^2 \rangle / (2 \langle v_t^2 \rangle)$ where $\langle v_r^2 \rangle$ and $\langle v_t^2 \rangle$ are the radial and tangential velocity second moments (Binney & Tremaine, 1987). Given the nearly isotropic conditions found in the central part of simulated dark halos, this already seems to indicate that the density profile cannot be more shallow than $\rho \sim r^{-1}$.

The idea of looking for constraints between the central density slope and the anisotropy is an excellent one. In §2, we shall prove that if the density is cusped like $r^{-\gamma}$ near the center, then the limiting value of $\beta$ at the center may not be greater than $\gamma/2$. This relation is indeed suggested by solving the Jeans equation for constant $\beta$. That is, the one-dimensional radial velocity dispersion obtained as the solution, in general, diverges at the center if $\gamma < 2\beta$, which is unphysical unless the central potential well depth is infinite. In fact, we will show that the inequality $\gamma \geq 2\beta$ is the necessary condition for the non-negativity of the DF.

2. PROOF OF A CUSP SLOPE-ANISOTROPY THEOREM

Here, we shall prove that if the density is cusped like $r^{-\gamma}$ near the center, then the limiting value of $\beta$ at the center may not be greater than $\gamma/2$. This relation is indeed suggested by solving the Jeans equation for constant $\beta$. That is, the one-dimensional radial velocity dispersion obtained as the solution, in general, diverges at the center if $\gamma < 2\beta$, which is unphysical unless the central potential well depth is infinite. In fact, we will show that the inequality $\gamma \geq 2\beta$ is the necessary condition for the non-negativity of the DF.

2.1. Constant Anisotropy Distribution Functions

First, let us suppose that the DF is given by the ansatz

$$f(E, L) = L^{-2\beta} f_c(E)$$

where $L$ is the specific angular momentum, and $f_c(E)$ is a function of the binding energy $E$ alone. This seems as though it is a restrictive assumption, but this is not really the case.

Rather, equation (1) arises naturally as the most divergent term in a Laurent expansion with respect to $L$ at $L = 0$ for a very wide class of DFs. By integrating equation (1) over purely radial orbits cannot be supported by a density cusp shallower than the isothermal cusp (i.e., $\gamma \geq 2\beta = 2$, see Richstone & Tremaine, 1984). In §3, we study the scale-free power-law cusps that inspired Hansen (2004) and show that the inequality $\gamma \geq 1 + \beta$ is related to the boundary condition at infinity rather than at the center. Finally, in §4, we consider the generalization of the theorem to tracer populations in an externally imposed cusped potential — for example, to stars moving around a central black hole. In particular, with the potential cusped as $r^{-\delta}$ (0 $\leq \delta \leq 1$), we find that the inequality becomes $\gamma \geq 2\beta + (1/2 - \delta)\beta$. While a similar limit has been noted in the literature for the case when the DF is scale-free (White, 1981; de Brujine, van der Marel, & de Zeeuw, 1996), we derive the limit as a general condition for a DF with a centrally diverging (and not necessarily self-consistent) potential.

2 MIT Kavli Institute for Astrophysics & Space Research, Massachusetts Institute of Technology, 77 Massachusetts Ave., Cambridge, MA 02139, USA; jinan@space.mit.edu

3 Strictly speaking, the ansatz is valid only for $\beta < 1$. However, it can be extended to $\beta = 1$ using the relation $\lim_{\beta \to 1} [L^{-2\beta} f_c(1 - \beta)] = \delta(L^2)$ where $\delta(L)$ is the Dirac delta function. Subsequently, equations (1) and (2) are still valid for $f(E, L) = \delta(L^2) f_c(E)$ as the $\beta = 1$ limit simply without the $f_c(1 - \beta)$ factor.
velocity space, we find that the density is given by

\[ \rho = r^{-2\beta} \bar{D}_\beta \int_0^\infty (\psi - E)^{1/2 - \beta} f_E(E) dE, \]  

(2)

\[ \bar{D}_\beta = \frac{(2\pi)^{3/2} \Gamma(1 - \beta)}{2\Gamma(3/2 - \beta)} \]

(3)

where \( \psi \) is the relative potential and \( \Gamma(x) \) is the Gamma function. The unknown function \( f_E(E) \) can be found from the formula [Cuddeford 1991; Kochanek 1996; Wilkinson & Evans 1993; An & Evans 2006; Evans & An 2006]

\[ f_E(E) = C_\beta \left[ \int_0^E \frac{d\psi - d\psi + 1 h}{(E - \psi)^{\alpha}} \right] \]

(4)

\[ C_\beta = \frac{2^\beta}{(2\pi)^{3/2} \Gamma(1 - \alpha) \Gamma(1 - \beta)}. \]

(5)

Here, \( h = r^{2\beta} \) is expressed as a function of \( \psi \), and \( \eta = (3/2 - \beta) \) and \( \alpha = 3/2 - \beta - n \) are the integer floor and the fractional part of \( 3/2 - \beta \). It is a simple exercise to show that the anisotropy parameter for this model is the same as the parameter \( \beta \) in the expression of DF (eq. 1).

By considering the limit of equation (2) as \( r \to 0 \) one may infer that \( \rho \) should diverge at least as fast as \( r^{-2\beta} \) if \( \beta > 0 \) and cannot approach zero faster than \( r^{(2-\beta)} \) if \( \beta < 0 \) unless the integral vanishes in the same limit. This fact is the basic argument that leads to the theorem. In the following, we provide a more stringent proof of the theorem.

2.1.1. The Case \( \beta \leq 1/2 \)

For \( \beta < 1/2 \), a direct generalization of the proof of [Tremaine et al. 1994] for isotropic models suffices. That is, from equation (4), we find that

\[ \frac{d}{d\psi} \left( r^{2\beta} \rho \right) = D_\beta \int_0^\infty \frac{f_E(E) dE}{(\psi - E)^{1/2 - \beta}} \geq 0, \]

(6)

\[ \bar{D}_\beta = (1/2 - \beta)D_\beta = \frac{(2\pi)^{3/2} \Gamma(1 - \beta)}{2\Gamma(1/2 - \beta)} \]

(7)

for any physical DF, as the integrand is always positive. Similarly, if \( \beta = 1/2 \), then

\[ \frac{d}{d\psi} (r\rho) = 2\pi^2 \frac{d}{d\psi} \int_0^\infty f_E(E) dE = 2\pi^2 f_E(\psi) \geq 0. \]

(8)

However,

\[ \frac{dh}{dr} = \frac{dr}{d\psi} \frac{h d\ln h}{d\ln r} = \frac{r^{2\beta - 1} \rho}{d\psi / dr} \left( 2\beta + \frac{d\ln \rho}{d\ln r} \right). \]

(9)

Since \( d\psi / dr \leq 0 \) for any physical potential, we thus find that

\[ 2\beta \leq -\frac{d\ln \rho}{d\ln r}. \]

(10)

This holds everywhere. Specializing to the limit at the center, we obtain the desired result.

2.1.2. The Case \( \beta > 1/2 \)

When \( \beta > 1/2 \), equation (8) is invalid, and therefore, a different proof is required. For this purpose, we first note that

\[ \frac{1}{(\psi - E)^{\beta - 1/2}} > \frac{1}{\psi^{\beta - 1/2}} > 0 \]

(11)

for \( 0 < E < \psi \) and \( \beta > 1/2 \). Then, from equation (2), we find that

\[ \rho > \frac{D_\beta}{r^{2\beta} \psi^{3/2 - 1/2}} \int_0^\infty f_E(E) dE. \]

(12)

Therefore,

\[ \lim_{r \to 0} \left( \rho r^{2\beta} \psi^{3/2 - 1/2} \right) > D_\beta \int_0^\infty f_E(E) dE > 0 \]

(13)

where \( \psi_0 = \psi(\rho = 0) \). Next, if we consider the case when \( \psi_0 \) is finite (see §4 for the centrally diverging potential), we have

\[ \lim_{r \to 0} \left( \rho r^{2\beta} \psi^{3/2 - 1/2} \right) = \psi_0^{\beta - 1/2} \lim_{r \to 0} (\rho r^{2\beta}) > 0. \]

(14)

Since \( \psi_0 > 0 \), we find that \( \lim_{r \to 0} (\rho r^{2\beta}) > 0 \), that is, \( \lim_{r \to 0} \rho \) is either non-zero positive and finite or diverges to positive infinity. If the former is the case, it is straightforward to show that (using L’Hôpital’s rule)

\[ \lim_{r \to 0} h = \lim_{r \to 0} \frac{hr}{r} = \lim_{r \to 0} \frac{d(hr)}{dr} = \lim_{r \to 0} h \frac{d \ln(hr)}{d \ln r}. \]

(15)

and consequently that

\[ \lim_{r \to 0} \frac{d \ln(hr)}{d \ln r} = 1 \Rightarrow \lim_{r \to 0} \frac{d \ln h}{d \ln r} = 0. \]

(16)

On the other hand, if \( \lim_{r \to 0} h \) is divergent, L’Hôpital’s rule indicates that

\[ \lim_{r \to 0} \frac{d \ln h}{d \ln r} = \lim_{r \to 0} \frac{\ln h}{\ln r}. \]

(17)

However, we have \( (\ln h) / (\ln r) < 0 \) for sufficiently small \( r \) so that

\[ \lim_{r \to 0} \frac{\ln h}{\ln r} \leq 0 \Rightarrow \lim_{r \to 0} \frac{d \ln h}{d \ln r} \leq 0. \]

(18)

Hence, for both cases,

\[ \lim_{r \to 0} \frac{d \ln h}{d \ln r} = \lim_{r \to 0} \frac{d \ln \rho}{d \ln r} + 2\beta \leq 0 \]

(19)

\[ \therefore 2\beta \leq -\frac{d \ln \rho}{d \ln r} \geq 2\beta, \]

(20)

which is the desired result.

2.2. General (Analytic) Distribution Functions

This result is in fact far more general than the assumed ansatz for the DF (eq. 1). For example, [Cioffi & Pellegrini 1993] found the same limit (\( \gamma = 2\beta = 0 \)) for the Osipkov type DF, which is manifestly not in the form of equation (1). We extend the limit derived in the preceding section to a wide class of DFs by the following simple argument. In general, any analytic DF can be expressed either as sums of equation (1) or in terms of a Laurent series expansion with respect to \( L \) or \( L = 0 \) (really a special class of the former). Then, since \( L = r^2 \), as \( r \to 0 \), the DF is dominated by the term associated with the leading order of \( L \), and consequently so is the behavior of the density near the center. It is also straightforward to show that the anisotropy parameter at the center is indeed determined by \( \beta_0 \) where \( -2\beta_0 \) is the power to the leading term of \( L \). The desired result, therefore, follows from the preceding proof for the special case of the DF with a single term. In Appendix A, we discuss the conditions of applicability of the proof more mathematically and argue that the theorem holds for all physically reasonable DFs of spherical systems.
We find that the cusp slope-anisotropy theorem ($\gamma \geq 2\beta$) is actually quite reasonable. It implies that, if the anisotropy is radially biased ($\beta > 0$) near the center, the density is cusped, and that, unless the cusp slope is steeper than that of isothermal cusps ($\gamma = 2$), there is a finite upper limit to $\beta$ that is strictly smaller than unity. Similarly, if the density is cored ($\gamma = 0$), the central anisotropy is either tangentially biased or at most isotropic.

3. SCALE-FREE DENSITY PROFILE

Recently, Hansen (2003) derived a similar but stricter inequality $\gamma \geq 1 + \beta$, based on the condition that there exists a physical power-law solution to the spherically symmetric Jeans and Poisson equations with EoS, $\rho \propto r^{-\gamma}$. Since $\beta \leq 1$, his result is stronger than our result. However, we note that his result is strictly valid only if both $\rho$ and $\langle v_z^2 \rangle$ behave as the pure-power law extending globally to the infinity. In fact, we find that the condition $\gamma \geq \beta + 1$ originates from the boundary condition at infinity rather than at the center, and thus, argue that the result should be understood to refer to the asymptotic density power-index at infinity, not the central density slope. In particular, the supposed piece of evidence cited by Hansen (2003) for his inequality, (Lokas & Hoffman 2000), see also Bouvier & Janin 1968 is in fact due to the constraint imposed by $\gamma > 2\beta$ on the central slope through the positivity of the DF ($\gamma$ see also Richstone & Tremaine 1984), since it involves the case of purely radial motion ($\beta = 1$) for which the two limits coincide ($\gamma \geq 2$).

The general integral solution of Jeans equation with constant $\beta$ can be written by introducing an integration constant $\bar{B}$

$$ r^{2\beta} \rho (\langle v_z^2 \rangle) = B + \int_{r_0}^{r} dr' r^{2\beta} \rho(r') \frac{d\nu}{dr'} . $$

The potential gradient (i.e., the local gravitational acceleration) can be found from the enclosed mass

$$ \frac{d\nu}{dr} = -\frac{GM_r}{r^2} ; \quad M_r = M_{r_0} + 4\pi \int_{r_0}^{r} \rho(r') r^2 dr' . $$

where the negative sign is due to our choice of sign for $\psi$. If we assume a strict power-law behavior for the density as $\rho = Ar^{-\gamma}$ where $A > 0$ is constant, then $M_r$ is given by ($\gamma \neq 3$)

$$ M_r = M_{r_0} + 4\pi A (3 - \gamma)^{-1} (r^{-\gamma} - r_{0}^{-\gamma}) . $$

If the power-law extends to the center, the result must be valid with the choice of $r_0 = 0$. However, then, the mass within any finite radius $M_r$ always diverges for $\gamma > 3$ even if $M_0$ is finite, and therefore, the model is unphysical. The resulting upper limit $\gamma < 3$ is well-established. By substituting equation (22) and $\rho = Ar^{-\gamma}$ in equation (24), $\langle v_z^2 \rangle$ as a function of $r$, $\gamma \neq 3$, $\gamma \geq \beta + 1$, and $\gamma \neq 2\beta - 1$ is found to be

$$ \langle v_z^2 \rangle = Br^{-2\gamma} - r^{-2\gamma} + \frac{2\pi GA}{(3 - \gamma)(\beta - \gamma + 1)} $$

where $B$ is an integration constant to be determined from the boundary condition. Here, if we assume strictly scale-free behavior for $\rho$, equation (24) is valid everywhere extending from $r = 0$ to $r = \infty$. With $r_0 = 0$ and $M_0 = 0$, we can show that the condition for $\langle v_z^2 \rangle$ to be non-negative everywhere leads to the inequality $\gamma > \beta + 1$, as found by Hansen (2004), and $B \geq 0$. In addition, the self-similarity implies strict power-law behavior for $\langle v_z^2 \rangle$ as well. Since $A > 0$, this can only be obtained with the choice of $B = 0$. In fact, the choice of $B = 0$ can independently be deduced from the boundary condition at infinity. That is, $\langle v_z^2 \rangle$ is non-divergent for a finite potential ($\gamma < 2$), or if the potential diverges ($\gamma > 2$), the velocity dispersion cannot diverge faster than the potential does.

However, if we relax the assumption that $\rho$ is strictly scale-free everywhere and replace it with $\rho$ being locally well-approximated by the power-law near the center, equation (24) is valid only for the region where $\rho \approx Ar^{-\gamma}$ so that the condition that $\langle v_z^2 \rangle$ is non-negative only needs to be checked for this regime. Provided that the power-law provides a good approximation to the behavior of $\rho$ near the center and we limit attention to a self-consistent density-potential system, it is reasonable to choose $r_0 = 0$ and $M_0 = 0$. Then, for $\gamma > 2\beta$, with any positive constant $B$, equation (24) returns the correct behavior of the velocity dispersion near the center, although its validity does not extend to infinity. For $\gamma > \beta + 1$, the velocity dispersion ($r_0 = M_0 = 0$) is given by

$$ \langle v_z^2 \rangle = r^{2\gamma} \left[ \frac{2\pi GA}{(3 - \gamma)(\beta - \gamma + 1)} + Br^{2(\gamma - 1)} \right] . $$

Near the center, we find that $\langle v_z^2 \rangle \sim A'(r^2)^{-\gamma}$, where $A'$ is a constant positive. This is just the approximate local power-law behavior of the velocity dispersion near the center (valid locally for any $B$). In addition, if $\beta + 1 < \gamma$, the central velocity dispersion is finite. Although $\langle v_z^2 \rangle$ diverges at the center if $\gamma > 2 \geq \beta + 1$, this behavior can be physical because the self-consistent potential well depth for this case is also infinite. On the other hand, if $\gamma < \beta + 1$, the same velocity dispersion can be written as

$$ \langle v_z^2 \rangle = r^{2\gamma} \left[ B - r^{2(\beta + 1) - \gamma} \left( \frac{2\pi GA}{(3 - \gamma)(\beta + 1 - \gamma)} \right) \right] . $$

In other words, since $\gamma - 2\beta < 2 - \gamma$ if $\gamma < \beta + 1$, the leading term for the velocity dispersion near the center is given by $\langle v_z^2 \rangle \sim Br^{2\gamma - 2\beta}$ provided that $B \neq 0$. While not strictly scale-free, the local behavior of the velocity dispersion near the center can still be approximated as a power-law, and furthermore, as long as $B > 0$ and $0 \leq \gamma - 2\beta < 2 - \gamma$, it is positive and finite. While we note that, for a sufficiently large $r$, equation (26) eventually becomes negative since $\gamma - 2\beta$ term becomes dominant as $r \rightarrow \infty$, this does not restrict the central power-index for density, provided that the behavior of $\rho$ starts to deviate from $\sim Ar^{-\gamma}$ (toward the steeper fall-off) at smaller $r$ than the value at which $\langle v_z^2 \rangle = 0$ in equation (26).

Let us consider the explicit example of the Hernquist (1990) model, which has a $r^{-1}$-density cusp (i.e., $\gamma = 1$). The radial velocity dispersion of the constant $\beta$ model is (see e.g., Baes & Dejonghe 2002; Evans & An 2005)

$$ \langle v_z^2 \rangle = \frac{GM}{(5 - 2\beta)(r + a)} z F_1 \left( 1; 5; 6 - 2\beta; \frac{a}{r + a} \right) . $$

where the potential is given by $\psi = GM/(r + a)$. It is straightforward to show that, for $0 < \beta \leq 1/2$, $\langle v_z^2 \rangle$ is everywhere positive finite with its leading order behavior near the center given by $\sim r^{1 - 2\beta}$ (if $\beta = 1/2$, $\langle v_z^2 \rangle = \psi/4$, see also Evans & An 2005). On the other hand, if $\beta < 0$, the leading order for $\langle v_z^2 \rangle$ near the center is found to be $\sim r$ with a positive coefficient. For the isotropic case ($\beta = 0$), the elementary functional expression for the velocity dispersion is given in equation (10) of Hernquist (1990) whose leading order behavior is found to be $\sim r ln r^{-1}$ (see e.g., eq. 11 of Hernquist 1990).
As another example, we consider the dark matter profile proposed by Dehnen & McLaughlin (2005). They solved the spherically symmetric Jeans and Poisson equations with the same EoS as Hansen (2004). However, they found a family of 'realistic' models with a finite mass and an infinite extent. With \( \rho \propto r^{-3}(v_c^2)^{1/2} \), the inner density cusp of their models is given by \( \gamma = (7+10\beta_0)/9 \) where \( \beta_0 \) is the anisotropy parameter at the center. It is clear that, for all members of these models, \( \gamma < \beta + 1 \), thus violating the inequality \( \gamma \geq \beta + 1 \). On the other hand, our result \( \gamma \geq 2\beta \) indicates that they are physical if and only if \( \beta_0 \leq (7/8) \). In fact, \( (v_c^2) \) near the center for this family behaves as \( \sim r^{(7-8\beta_0)/9} \), and thus, the limit \( \gamma \geq 2\beta \) is equivalent to the condition that the central velocity dispersion is finite.

A similar analysis of equation (24) can be applied to discover the asymptotic behavior of the velocity dispersion at infinity. Suppose that \( \rho \) asymptotically approaches a power-law for a sufficiently large \( r \). Then, for the same range, equation (24) is a valid expression for \( \langle v_c^2 \rangle \), provided that the power-law \( \sim A r^{-\gamma} \) describes the asymptotic behavior of \( \rho \) and \( M_{r_0} \) is the mass within \( r_0 \). Here, \( B = 0 \) from the boundary condition at infinity. If the total mass is finite \( (\gamma > 3 > \beta + 1 > 2\beta - 1) \), we can simply set \( r_0 = \infty \) and \( M_{\infty} = M \) where \( M \) is the total mass. Then, since \(-1 > 2 - \gamma\), the asymptotic behavior of the velocity dispersion is given by \( \langle v_c^2 \rangle \sim (\gamma - 1 - 2\beta)^{-1}GM/r \), which is consistent with Keplerian fall-off. For an infinite mass system, we find that \( 2 - \gamma > -1 \), and thus the leading term of \( \langle v_c^2 \rangle \) for \( r \rightarrow \infty \) is \( \sim A r^{-\gamma} \). Here, \( A' \) is a positive constant if \( \gamma > \beta + 1 \), whereas it is a negative constant if \( \gamma < \beta + 1 \). In other words, from the condition of non-negativity of the velocity dispersion toward infinity, we actually recover the inequality of Hansen (2004). \( \gamma \geq \beta + 1 \), although here \( \gamma \) and \( \beta \) are the asymptotic density power-index and the anisotropy parameter at infinity. Although the velocity dispersion diverges as \( r \rightarrow \infty \) if \( \gamma < 2 \), the behavior may be acceptable because the potential also diverges with the same power-index, so that the system is still bounded.

4 CENTRAL BLACK HOLE

We have found one further example of a cusp slope-anisotropy relationship in the literature. White (1981) found a relation\(^4\) by studying the special case of scale-free densities in scale-free potentials, namely

\[
\gamma \geq \frac{\delta}{2} + \beta(2 - \delta),
\]

(28)

where \( \delta \) is the central power-law index for the potential (i.e., \( \psi \sim r^{-\delta} \)), which may be externally imposed. Note the change of the notation from White (1981). The form of the limit given in equation (28) is actually that of de Brujine et al. (1996), who performed a similar study to White (1981), but allowed for flattening. This result is derived from a specific functional form for the DF, and in particular, assumes that \( f_E(E) \) is scale-free. We note that, since \( \beta \leq 1 \), the inequality \( \gamma \geq 2\beta \) is automatically satisfied if \( \gamma \geq 2 \). For \( \gamma < 2 \), the self-consistent potential-density has a finite central potential so that \( \delta = 0 \). In this case, equation (28) reduces to \( \gamma \geq 2\beta \). However, in the presence of a central black hole (\( \delta = 1 \)), equation (28) provides us with a different limit \( \gamma \geq \beta + (1/2) \), which is stricter than \( \gamma \geq 2\beta \) if \( \beta < 1/2 \).

Here, we note that this limit can, without any assumption of scale-free-ness of the density or DF, be derived from the non-negativity of the DF for a massless tracer populations in the Keplerian potential of a central point mass. Let us suppose that the DF for a massless tracer populations is given by equation (1). (The results can then be extended to more general DFs using the identical argument of §2.) Next, we assume that these tracers are subject to the potential \( \psi = GM/r \) of a point mass at the center. Then, the number density of the tracer population \( n \) can be found from integration of the DF over velocity space as equation (2).

\[
n = \frac{D\beta}{r^{2\beta}} \int_0^{GM/r} \frac{(GM - E)^{1/2 - \beta}}{r - E} f_E(E) \, dE
\]

(29)

For \( \beta < 1/2 \), we find that

\[
\frac{d}{dr} \left( r^{\beta + 1/2} n \right) = -\frac{2}{\beta} \frac{D\beta}{r^{2\beta}} \int_0^{GM/r} \frac{E f_E(E) \, dE}{(GM - rE)^{1/2 + \beta}} \leq 0
\]

(30)

for any non-negative DF. Consequently,

\[
\frac{d}{dr} \left( r^{\beta + 1/2} n \right) = \frac{\beta - 1}{2} + \frac{d \ln n}{d \ln r} \leq 0
\]

(31)

or, equivalently,

\[
- \frac{d \ln n}{d \ln r} \geq \frac{\beta - 1}{2}
\]

(32)

which is the desired result. In fact, if the external potential is replaced by \( \psi = C/r^{\delta} \) in equation (29), it is easy to see that equation (28) simply follows from an essentially identical argument with \( \gamma - (d \ln n/d \ln r) \) being the central power-index for the number density of the tracer population.

In fact, the result can be still obtained without assuming the specific form of (scale-free) potential. That is, provided that \( \gamma = \lim_{r \to 0} (d \ln \psi / d \ln r) \) and \( 0 \leq \gamma \leq 1 \), we find from equation (2) that

\[
n = \frac{D\beta}{r^{2\beta}} \int_0^{\psi} \left( 1 - \frac{E}{\psi} \right)^{1/2 - \beta} f_E(E) \, dE,
\]

(33)

and thus, for \( \beta < 1/2 \), we have

\[
\frac{d}{d\psi} \left( n r^{2\beta} \psi^{-\beta - 1/2} \right) = \frac{D\beta}{r^{2\beta}} \int_0^{\psi} \frac{E f_E(E) \, dE}{\psi^{1/2 - (E/\psi)^{1/2 + \beta}}} \geq 0.
\]

(34)

However, of course,

\[
\frac{d}{d\psi} \left( n r^{2\beta} \psi^{-\beta - 1/2} \right) = \frac{n r^{2\beta} \psi^{-\beta - 3/2}}{d \ln \psi / d \ln r} \frac{d}{d \ln r} \left( \frac{d \ln n}{d \ln r} + 2\beta + \left( 1 - \frac{1}{2} \frac{d \ln \psi}{d \ln r} \right) \geq 0. \right)
\]

(35)

and by taking the limit \( r \to 0 \),

\[
\gamma \geq 2\beta + \left( \frac{1}{2} - \beta \right) \delta.
\]

(36)

Here, note that \( \lim_{r \to 0} (d \ln \psi / d \ln r) = -\delta \leq 0 \). This also indicates that the result is still valid even if the self-gravity of the tracer population is appreciable, as long as the potential (that may be de-coupled from the density) is divergent at the center.

If \( \beta = 1/2 \), the limit given in equation (28) is, in fact, identical to \( \gamma \geq 2\beta = 1 \). Since the derivation of the limit in §2 for \( \beta = 1/2 \) does not use the assumption of self-consistency, it is still applicable here. Therefore, the limits in equation (32)
We have proved, for a very wide class of steady-state gravitating system, a theorem constraining the central cusp slope of the density profile $\gamma$ (eq. 20) and the central velocity anisotropy $\beta$. Specifically, the inequality $\gamma \geq 2\beta$ is a necessary condition for the non-negativity of the distribution function (DF). If there is a divergent external potential, decoupled from the density profile, then the inequality generalizes to $\gamma \geq 2\beta - (\beta - 1/2)\delta$. Here, the external potential diverges as $\sim r^{-\delta}$ at the center. Finally, if the external potential is due to a central black hole, it reduces to $\gamma \geq \beta + (1/2)$. We expect our result to be useful in the study of dense stellar systems, or in the building of extreme stellar dynamical models.

We thank P. Tim de Zeeuw for stimulating discussions and helpful suggestions. We appreciate the generous suggestions made by the anonymous referee to improve the paper. We are grateful to Simon D. M. White for noticing a flaw in an earlier version. We acknowledge S. Hansen for pointing us to the results of [Dehnen & McLaughlin (2005)] and others.

APPENDIX

Here, we provide a more detailed argument for the generality of the theorem than that given in § 2.2. While we do not claim that the following argument strictly adheres to the high standard of the pure mathematician, we hope that it indicates the generality of the result.

First, let us suppose that a DF $f(E, L)$ can be written as

$$f(E, L) = L^{-2\beta} [f_0(E) + f_1(E, L)]$$  \hspace{1cm} (A1)

where $f_0(E)$ is a function of $E$ alone whereas $f_1(E, L)$ is a function that satisfies

$$f_1(E, L = 0) = 0,$$  \hspace{1cm} (A2)

which further implies that $f_0(E) \geq 0$ for all accessible values of $E$ from the non-negativity of the DF. Then,

$$\rho = 2\pi \int L^{-\beta} [f_0(E) + f_1(E, L)] v_r dv_r dv_r,$$
\[ \lim_{r \to 0} \beta = 1 - \lim_{r \to 0} \frac{\rho(v_T^2)}{2\rho(v^2)} = 1 - (1 - \beta_0) = \beta_0. \]  

(\text{A6})

Next, suppose that \( h_0 = r^{2\beta_0} \rho_0 \) and \( \rho_0 \) is the density profile built by the DF, \( f(E, L) = L^{-2\beta_0} f_0(E) \). Then, the proof given in §2.1 indicates that \( \gamma_0 \geq 2\beta_0 \) where

\[ \gamma_0 = -\lim_{r \to 0} \frac{d \ln \rho_0}{d \ln r}. \]  

(\text{A7})

Now, since \( \lim_{r \to 0} (d \ln h_0 / d \ln r) = 2\beta_0 - \gamma_0 \leq 0 \), we have \( \lim_{r \to 0} h_0 \neq 0 \), that is, \( \lim_{r \to 0} h_0 \) is non-zero finite or diverges. Subsequently, from equation (\text{A3}),

\[ \lim_{r \to 0} \left( r^{2\beta_0} \rho - h_0 \right) = \lim_{r \to 0} \left( \frac{r^{2\beta_0} \rho}{h_0} - 1 \right) h_0 = 0, \]  

(\text{A8})

but \( \lim_{r \to 0} h_0 \neq 0 \), and therefore, we find that

\[ \lim_{r \to 0} \frac{r^{2\beta_0} \rho}{h_0} = 1. \]  

(\text{A9})

If \( \lim_{r \to 0} h_0 \) is finite (i.e. \( \gamma_0 = 2\beta_0 \)), then equation (\text{A9}) implies that

\[ 0 < \lim_{r \to 0} r^{2\beta_0} \rho = \lim_{r \to 0} h_0 < \infty \]  

(\text{A10})

and so \( \lim_{r \to 0} r^{2\beta_0} \rho \) is also finite, that is \( \rho \sim r^{-2\beta_0} \). On the other hand, if \( \lim_{r \to 0} h_0 = \infty \), L'Hôpital's rule indicates that

\[ \lim_{r \to 0} \frac{r^{2\beta_0} \rho}{h_0} = \lim_{r \to 0} \frac{d(r^{2\beta_0} \rho) / dr}{dh_0 / dr} = \lim_{r \to 0} \frac{d \ln(r^{2\beta_0} \rho)}{d \ln h_0} \frac{d \ln h_0 / dr}{d \ln h_0 / d \ln r} = \frac{1}{2\beta_0 - \gamma_0} \left( 2\beta_0 - \lim_{r \to 0} \frac{d \ln \rho}{d \ln r} \right) = 1. \]  

(\text{A11})

In other word, combining the results in equations (\text{A10}) and (\text{A11}), we have established that

\[ \lim_{r \to 0} \frac{d \ln \rho}{d \ln r} = \gamma_0 = \lim_{r \to 0} \frac{d \ln \rho_0}{d \ln r}. \]  

(\text{A12})

where \( \rho \) is the density profile built by the DF of equation (\text{A1}) and \( \rho_0 \) by \( f(E, L) = L^{-2\beta_0} f_0(E) \). Finally, taking equations (\text{A6}) and (\text{A12}) together, we have established that the theorem \( \gamma_0 > 2\beta_0 \) extends to more general class of DFs of the form of equation (\text{A1}).

How general is the form of DF in equation (\text{A1})? We argue that it is almost always possible to reduce most well-behaving DFs to the form of equation (\text{A1}). That is, for a general DF of a spherically symmetric system in equilibrium, the reduction is possible if there exists \( \alpha < 2 \) such that

\[ f_E(E) = \lim_{L \to 0} L^\alpha f(E, L). \]  

(\text{A13})

where \( f_E(E) \) should be finite and non-zero for values of \( E \) at least in some non-empty subset of all the accessible values of \( E \in [0, \psi_0] \). Then, the original DF can be written in a form of equation (\text{A1}) as

\[ f(E, L) = L^{-\alpha} \left[ f_E(E) + f_1(E, L) \right]; \quad f_1(E, L) = L^\alpha f(E, L) - f_E(E). \]  

(\text{A14})

and it is obvious to show that

\[ f_1(E, L = 0) = \lim_{L \to 0} L^\alpha f(E, L) - f_E(E) = 0. \]  

(\text{A15})

For example, for the DF of the form given by [Cuddeford (1991)]

\[ f(E, L) = L^{-2\beta_0} f_0(Q); \quad Q \equiv E - \frac{L^2}{2\beta^2}, \]  

(\text{A16})

the reduction is given by

\[ f(E, L) = L^{-2\beta_0} \left[ f_0(E) + f_1(E, L) \right]; \quad f_1(E, L) = f_0(Q) - f_0(E). \]  

(\text{A17})
