We introduce a classical limit of the dynamics of quantum spin systems based on coherent states of SU(N), where N is the dimension of the local Hilbert space. This approach, which generalizes the well-known Landau-Lifshitz dynamics from SU(2) to SU(N), provides a better approximation to the exact quantum dynamics for a large class of realistic spin Hamiltonians, including S ≥ 1 systems with large single-ion anisotropy and weakly-coupled multi-spin units, such as dimers or trimers. We illustrate this idea by comparing the spin structure factors of a single-ion S = 1 model that are obtained with the SU(2) and SU(3) classical spin dynamics against the exact solution.

I. INTRODUCTION

The concept of a “coherent state” was first proposed by Schrödinger in 1926 [1]. He derived the state as the most classical (i.e., minimum uncertainty Schrödinger in 1926 [1]). He derived the state as the most classical state of a quantum harmonic oscillator. The first practical application of this concept was introduced by Glauber and Sudarshan in 1963 [2–5] to describe the maximal coherent light state in quantum optics, hence the name coherent state. Coherent states were originally constructed as eigenstates of the annihilation operator and they were generated by applying a displacement operator of the Heisenberg-Weyl group to the vacuum state of the harmonic oscillator. In his third seminal paper [4], Glauber pointed out that there are three equivalent definitions of coherent states: (i) the eigenstate of the annihilation operator, (ii) the state obtained by applying a displacement operator of the Heisenberg-Weyl group on the vacuum state of the harmonic oscillator, and (iii) the state with minimum Heisenberg uncertainty. Ten years later, Perelomov [6] and Gilmore [7] observed that the second definition of Glauber can be extended to an arbitrary Lie group. This generalization was later considered by Yaffe to explore the classical limit of quantum systems [8]. Moreover, using this generalization of coherent states, one can extend and prove Dirac’s conjecture— the commutator between two quantum operator times 1/(iℏ) is replaced by the Poisson bracket in the classical limit—for general Lie groups, where the Poisson bracket is defined on the classical phase space defined by the orbit of coherent states.

Classical limits of N-level quantum systems based on SU(N) coherent states have been exploited in different areas of physics [9, 10], ranging from atomic physics [11–15] to quantum chromodynamics [16, 17]. The main goal of this work is to present a comprehensive discussion of the classical dynamics of a quantum spin system based on SU(N) coherent states. To understand our motivation, we must first recognize that there are two widely used tools for modeling spin dynamics: the spin-wave theory (SWT) and the Landau-Lifshitz dynamics (LLD). The traditional SWT is a semi-classical approach, whose starting point is a mean-field state consisting of a direct product of SU(2) coherent states [18–24]. Quantum effects are incorporated order by order via a 1/S expansion [25–30]. The LLD was first introduced by Landau and Lifshitz [31] to describe the precession of the magnetization in a solid. In this classical approximation, the state of the system is approximated by a direct product of SU(2) coherent states at any time t. In the absence of damping, the classical LLD equations can be obtained by taking the classical limit of the Heisenberg equation following Dirac’s prescription.

While SWT and LLD become exact in the large-S limit, their applicability to real spin systems (with a finite value of S) is not just limited by the presence of large quantum fluctuations. As we will discuss in this work, there are large classes of realistic spin models whose spin dynamics is not well described by the traditional SWT or LLD, but still admit an accurate semi-classical or classical treatment. This apparent paradox disappears when we recognize that there is more than one way of taking the classical limit of a spin system [13].

The existence of multiple classical limits is tied to different choices of the Lie group that defines the orbit of coherent states [6, 8, 13, 32]. For instance, for a three-level system (S = 1) we can either use a mean field state that is a direct product of SU(2) coherent states or one that is a direct product of SU(3) coherent states. The second of these is the starting point of the so-called generalized SWT [33], which has been successfully applied to several models and quantum magnets [34–42]. An obvious advantage of the use of SU(3) coherent states for S = 1 systems is that they allow to describe local quadrupolar and dipolar moments (and their fluctuations) on an equal foot. [33] In contrast, SU(2) coherent states can only account for dipolar ordering and dipolar fluctuations.

The SU(N) generalization of the semiclassical 1/S expansion [42], suggests that the classical limit or LLD dynamics must also be generalized. However, to the best of our knowledge, the application of the classical SU(N) dynamics to spin systems has not been discussed in the literature. Although the classical limit of a quantum theory based on SU(N) coherent states (for N > 2) was discussed in Refs. [13, 32], these works were mainly focused on mathematical aspects of the SU(N) coherent states. After recognizing that quantum theories of N-level systems admit more than one classical limit, it becomes relevant to ask what is the most adequate choice for each particular application. In this work we focus on applications to spin Hamiltonians. Our main motivation is to demonstrate that the above-mentioned generalization of Dirac’s conjecture leads to a natural generalization of the LLD, that can be used to model...
the excitation spectrum of large classes of quantum magnets for which the traditional LLD dynamics is simply inadequate.

This paper is organized as follows. In Sec. II we review the properties of the coherent states of the Heisenberg-Weyl group, which consists of translation operators of a quantum mechanical point particle in phase space. In particular, we include the demonstration of Dirac's conjecture that was sketched by Yaffe in Ref. [8]. The inclusion of the intermediate steps of this demonstration is useful to motivate the general discussion on the classical limit of N-level quantum spin systems. In Sec. III we review the representation theory of the SU(N) group and the construction of the SU(N) coherent states for degenerate representations. This section includes the mathematical background that is needed for the later sections. The classical limit of a quantum spin system based on SU(N) coherent states is discussed in Sec. IV, where we show that the traditional classical limit \( h \to 0 \) is equivalent to the limit in which the dimension of the local Hilbert space of the system going to infinity. In Sec. V we use the generalized Dirac's conjecture to write down explicitly the classical equations of motion of the SU(2) and SU(3) generators. The generalization for SU(N) generators is discussed in the second part of Sec. V. In Sec. VI, we use a simple single-ion model to illustrate the importance of generalizing the LLD. The final conclusions are discussed in the Sec. VII.

II. COHERENT STATES FOR A POINT PARTICLE IN ONE DIMENSION

Together with the identity \( \hat{1} \), the position \( \hat{x} \) and momentum \( \hat{p} \) operators of a point particle in one dimension generate the so-called Heisenberg-Weyl group \( H_3 \). Correspondingly, these three operators form a basis of the Lie algebra \( h_3 \), whose structure is determined by the canonical commutation relations \([\hat{x}, \hat{p}] = i\hbar\) and \([\hat{x}, \hat{1}] = [\hat{p}, \hat{1}] = 0\). The identity, the creation and annihilation operators,

\[ \hat{a}^\dagger = \frac{\sqrt{i}}{\hbar} (\hat{x} - i\hat{p}), \quad \hat{a} = \frac{\sqrt{i}}{\hbar} (\hat{x} + i\hat{p}), \]

provide an alternative basis of \( h_3 \). The base state \( |0\rangle \) for coherent states is defined by the condition

\[ \hat{a}|0\rangle = 0. \]

A coherent state is obtained by applying an element of \( H_3 \) to the base state \[4\]

\[ |\alpha\rangle = e^{\alpha \hat{a}^\dagger - \bar{\alpha} \hat{a}} |0\rangle, \]

where \( e^{\alpha \hat{a}^\dagger - \bar{\alpha} \hat{a}} \in H_3 \) is the so-called displacement operator \[43\] and \( \alpha, \bar{\alpha} \in \mathbb{C} \). By convention, one can use two real numbers \( p \) and \( q \) with \( \alpha = q + ip \) to label a coherent state. The wave function of \( |\alpha\rangle = |p, q\rangle \) corresponds to the ground state of a simple harmonic oscillator centered around \( q \)

\[ |\langle x|p, q\rangle|^2 = (\pi \hbar)^{-1/2} \exp \left\{ (1/\hbar) \left| - (x - q)^2 \right| \right\}. \]

The manifold of coherent states forms an over-complete basis of the Hilbert space of a point particle in one-dimension \[44\].

The over-completeness is manifested by the finite overlap between two coherent states

\[ |\langle p, q|p', q'\rangle|^2 = \exp \left\{ -(1/2\hbar) \left| (p - p')^2 + (q - q')^2 \right| \right\} = \exp \left\{ -(1/2\hbar) (\alpha - \alpha') (\bar{\alpha} - \bar{\alpha}) \right\}. \]

The symbol without the hat denotes the expectation value of the corresponding operator for a coherent state:

\[ A(p, q) = \langle p, q|A|p, q\rangle. \]

Similarly, the expectation value of the product of two operators \( \langle p, q|AB|p, q\rangle \) is given by

\[ (AB)(p, q) = \int \frac{dp'dq'}{2\pi \hbar} |\langle p, q|p', q'\rangle|^2 \]

\[ \times \langle p, q|A|p', q'\rangle \langle p', q'|B|p, q\rangle \]

\[ \times \langle p', q'|p, q\rangle, \]

where we inserted the resolution of identity

\[ \hat{1} = \int \frac{dp'dq'}{2\pi \hbar} |p, q\rangle \langle p, q|. \]

Dirac's conjecture can be proved by taking the \( \hbar \to 0 \) limit of Eq. (7) \[8\]. According to Eq. (5), the first factor of the integrand of Eq. (7) is a Gaussian that has a sharp peak at \( p' = p \) and \( q' = q \) as \( \hbar \to 0 \). Moreover, notice that for fixed \( p \) and \( q \), the second factor is an analytical function of \( \alpha' = (q' + ip') \) and the third factor is an analytical function of \( \bar{\alpha}' = (q' - ip') \). Therefore, we can expand the second and the third factors up to quadratic order in \( \alpha' - \alpha \) and \( \bar{\alpha}' - \bar{\alpha} \), respectively,

\[ \frac{\langle p, q|A|p', q'\rangle}{\langle p, q|p', q'\rangle} = A(\alpha) + \frac{dA}{d\alpha} \bigg|_{\alpha = \alpha'} (\alpha' - \alpha) + \frac{1}{2} \frac{d^2A}{d\alpha'^2} (\alpha' - \alpha)^2 + O\left[(\alpha' - \alpha)^3\right], \]

\[ \frac{\langle p', q'|B|p, q\rangle}{\langle p', q'|p, q\rangle} = B(\bar{\alpha}) + \frac{dB}{d\bar{\alpha}} \bigg|_{\bar{\alpha} = \bar{\alpha}'} (\bar{\alpha}' - \bar{\alpha}) + \frac{1}{2} \frac{d^2B}{d\bar{\alpha}'^2} (\bar{\alpha}' - \bar{\alpha})^2 + O\left[(\bar{\alpha}' - \bar{\alpha})^3\right]. \]

By combining the results, we have

\[ (AB)(p, q) \approx \int \frac{d\alpha d\bar{\alpha}}{2\pi \hbar} |\langle \alpha|\alpha'\rangle|^2 \left\{ A(\alpha)B(\bar{\alpha}) + \frac{dA}{d\alpha} \frac{dB}{d\bar{\alpha}} (\alpha' - \alpha)(\bar{\alpha}' - \bar{\alpha}) + \mathcal{L} \right\}, \]

where \( \mathcal{L} \) includes terms (up to quadratic order) that vanish after the integration. After computing the Gaussian integrals and keeping contributions up to first order in \( \hbar \), we obtain

\[ (AB)(p, q) \approx A(p, q)B(p, q) + \hbar \frac{dA}{d\alpha} \frac{dB}{d\bar{\alpha}} (\alpha' - \alpha)(\bar{\alpha}' - \bar{\alpha}) \]

\[ + \mathcal{L}. \]

In the \( \hbar \to 0 \) limit, we have

\[ \lim_{\hbar \to 0} (AB)(p, q) = a(p, q)b(p, q), \]
where
\[ a(p,q) \equiv \lim_{\hbar \to 0} A(p,q), \quad b(p,q) \equiv \lim_{\hbar \to 0} B(p,q). \quad (14) \]

Note that the functions \( a(p,q) \) and \( b(q,p) \) are assumed to remain finite in the \( \hbar \to 0 \) limit. They are the so-called classical operators [8], that resemble the operators \( \hat{A} \) and \( \hat{B} \) in the classical limit. The relation (13) gives the factorization rule for the expectation value of the product of two operators in the \( \hbar \to 0 \) limit.

Finally, let us replace \( \hat{B} \) with the Hamiltonian operator \( \hat{H} \) and consider the \( \hbar \to 0 \) limit of the expectation value of the right hand side of the Heisenberg equation (HE) of motion [45]
\[
\lim_{\hbar \to 0} \frac{i}{\hbar} [A,H](p,q) = \lim_{\hbar \to 0} \left[ \frac{\partial A}{\partial p} \frac{\partial H}{\partial q} - \frac{\partial A}{\partial q} \frac{\partial H}{\partial p} \right] \\
= \frac{\partial a}{\partial q} \frac{\partial h}{\partial p} - \frac{\partial a}{\partial p} \frac{\partial h}{\partial q} \\
= \{ a(p,q), h(p,q) \}_{PB}, \quad (15)
\]
where \( h(p,q) = \lim_{\hbar \to 0} (p,q)\hat{H}(p,q) \) is the classical Hamiltonian. After taking the same expectation value of the left hand side of the HE, we obtain
\[
\lim_{\hbar \to 0} \langle p,q | \frac{d\hat{A}}{dt} | p,q \rangle = \frac{da(p,q)}{dt} = \{ a(p,q), h(p,q) \}_{PB}. \quad (16)
\]
This completes the proof of Dirac’s conjecture. Here the coherent states of \( \hat{H} \) play an important role in linking the quantum and classical theories for a point particle. As we already mentioned, the coherent states of \( \hat{H} \) can be generalized to any Lie group [6, 7], implying that we can take the classical limit of a given quantum theory by introducing a manifold of coherent states of an appropriate Lie group [8]. In the rest of this paper, we focus our discussion on the SU(N) group.

III. REVIEW OF THE SU(N) GROUP

A. Representation theory of SU(N)

In this section we review the representation theory of the Lie group SU(N) defined as the set of \( N \times N \) unitary matrices with determinant one and with the matrix multiplication as the group operation [46]. This group arises naturally in the description of an \( N \)-level quantum-mechanical system as the set of all unitary basis transformations with determinant equal to one. The Lie algebra \( \mathfrak{su}(N) \), that is defined as the tangent space at the identity element of \( SU(N) \), is a vector space over \( \mathbb{C}^N \) of dimension \( N^2-1 \). In the fundamental representation, the generators (bases) of \( \mathfrak{su}(N) \) are represented by the following matrices
\[
\hat{g}_{ij} (i \neq j), \quad \hat{H}_1 = \frac{1}{2} (\hat{g}_{11} - \hat{g}_{22}), \ldots, \hat{H}_{N-1} = \frac{1}{2} (\hat{g}_{N-1N-1} - \hat{g}_{NN}), \quad (17)
\]
where
\[
\hat{g}_{ij} \equiv |i\rangle \langle j|, \quad i,j = 1,2,\ldots,N \quad (18)
\]
and
\[
|i\rangle = (0, \ldots, \delta_{i0}, \ldots, 0)^T \quad (19)
\]
represents the standard basis of \( \mathbb{C}^N \). The matrices satisfy the following commutation relations
\[
[\hat{g}_{ij}, \hat{g}_{kl}] = \delta_{kj}\hat{g}_{il} - \delta_{il}\hat{g}_{kj}, \quad (20)
\]
and
\[
[\hat{H}_k, \hat{H}_l] = 0, \quad k,l = 1, \ldots, N-1, \quad (21)
\]
where the set of \( N-1 \) generators \( \{ \hat{H}_k \} \) with \( k = 1, \ldots, N-1 \) spans the Cartan subalgebra (maximal commutative subalgebra [46]), and the remaining \( N(N-1) \) generators \( \hat{g}_{ij} \) are the so-called raising (lowering) operators if \( i < j \) (\( i > j \)). It is important to keep in mind that any basis of matrices that obey Eqs. (20) and (21) provides a set of generators of \( \mathfrak{su}(N) \).

Consider a general irreducible representation (irrep) of \( \mathfrak{su}(N) \) on the vector space \( V \). The highest-weight state \( |\mu\rangle \in V \) is defined by the condition
\[
\hat{g}_{ij}|\mu\rangle \equiv 0 \quad \forall i < j, \quad (22)
\]
i.e. the highest weight state vanishes under the operation of any raising operator. Note that \( |\mu\rangle \) is also the common eigenvector of the Cartan subalgebra generators
\[
\hat{H}_1 |\mu\rangle = \frac{1}{2} \lambda_1 |\mu\rangle, \ldots, \hat{H}_{N-1} |\mu\rangle = \frac{1}{2} \lambda_{N-1} |\mu\rangle. \quad (23)
\]
The \( N-1 \) eigenvalues \( \{ \lambda_1, \ldots, \lambda_{N-1} \} \) are used to label the irreps of \( SU(N) \) and the dimension of the representation is given by Weyl’s dimension formula [47]. For the sake of simplicity, we will focus on \( \mathfrak{su}(2) \) and \( \mathfrak{su}(3) \). The Cartan subalgebra of \( \mathfrak{su}(2) \) is one-dimensional, and therefore its representation is labeled by a single number \( \lambda_1 \) with \( \text{dim}[\lambda_1] = \lambda_1 + 1 \), c.f. the familiar result \( \text{dim}[S] = 2S + 1 \) can be recovered by setting \( S = \lambda_1/2 \). Whereas for \( \mathfrak{su}(3) \), the irreducible representations are labeled by \( \lambda_1 \) and \( \lambda_2 \) and the dimension of the \( \{ \lambda_1, \lambda_2 \} \) is given by \( \text{dim}[\lambda_1, \lambda_2] = \frac{1}{2} (\lambda_1 + 1)(\lambda_2 + 1)(\lambda_1 + \lambda_2 + 2) \). For example, for a spin one system (three-level system) with a basis of states \( \{ |S\rangle = 1, |S\rangle = 2, |S\rangle = 0 \} \), the generators of the Cartan subalgebra are \( \hat{H}_1 = \hat{S}_z/2 \) and \( \hat{H}_2 = 3(\hat{S}_z)^2/4 - \hat{S}_z^2/4 - 1/2 \) and the highest-weight state of the above-mentioned fundamental representation of \( \mathfrak{su}(3) \) is the state \( |1\rangle \) (\( \hat{S}_z^2|1\rangle = |1\rangle \)) with \( \lambda_1 = 1 \) and \( \lambda_2 = 0 \), implying that the fundamental representation has \( \text{dim}[1,0] = 3 \). Note that the fundamental representation is a special example of a so-called “degenerate representation” with only one non-zero eigenvalue \( \lambda_k \). In this paper we will focus on the particular degenerate representations \( \{ \lambda_1, 0, \ldots, 0 \} \) that have a non-zero eigenvalue only for \( \lambda_1 \).

B. SU(N) coherent states

In this section we discuss the construction of SU(N) coherent states for degenerate representations. We start by considering the simplest non-trivial case corresponding to coherent
The three operators
\[ \hat{S}^+ = \hat{g}_{12}, \quad \hat{S}^- = \hat{g}_{21}, \quad \hat{S}^z = \hat{H}_1, \]
form a basis of \( \text{su}(2) \) generators. The corresponding highest-weight state \( |\mu\rangle = |S^z = S\rangle \) (hereafter we will use \( h \) as the unit of angular momentum), which satisfies \( \hat{S}^+|S^z = S\rangle = 0 \), is chosen as the reference state. Like any other state, \( |\mu\rangle \) is isomorphic to the coset space \( \text{SU}(2)/\text{U}(1) \) for the particular case of \( \text{SU}(2) \), the manifold of coherent states is invariant (up to a multiplicative phase)\(^{43} \). Since the manifold of the coherent states is isomorphic to \( \text{SU}(2)/\text{U}(1) \), it is necessary to identify the redundancy in the definition of coherent states, it is necessary to identify the isotropic subgroup \( I \), that leaves the reference state invariant up to a multiplicative phase\(^{43} \). Since \( I = \text{U}(1) \) for the particular case of \( \text{SU}(2) \), the manifold of coherent states is isomorphic to the coset space \( \text{SU}(2)/\text{U}(1) \): \( \Omega \in \text{SU}(2)/\text{U}(1) \):
\[ |\Omega(\theta, \phi)\rangle = e^{-i\theta S^z} e^{-i\phi S^z} |S^z = S\rangle, \quad (25) \]
where \( \hat{S}^y = \hat{S}^+ - i\hat{S}^- \) and \( \theta, \phi \) are two real parameters that parametrize the two-sphere \( S^2 \cong \text{CP}^1 \). In general, the manifold of the coherent states is isomorphic to \( G/I \) \(^{15,43} \), and it is known as the quotient orbit. In the fundamental representation of \( \text{SU}(2) \), an arbitrary \( \text{SU}(2) \) coherent state can be expressed as
\[ |\Omega(\theta, \phi)\rangle = \cos \frac{\theta}{2} e^{-i\phi/2} \hat{a}_1^\dagger |1\rangle + \sin \frac{\theta}{2} e^{i\phi/2} |2\rangle. \]
Let us consider now the case of \( \text{SU}(3) \) coherent states. The highest-weight state is again chosen to be the reference state. To identify the isotropic subgroup for degenerate representations, without loss of generality, we consider the highest-weight state \( |1\rangle = (1, 0, 0)^T \) in the fundamental representation of \( \text{SU}(3) \). Note that this state is invariant under the \( \text{SU}(2) \) group of transformations restricted to the orthogonal subspace. In addition, the global multiplication by a phase \( [\text{U}(1) \text{ subgroup}] \) also leaves the reference state invariant in the quantum mechanical sense, implying that the isotropic group under consideration is \( I = \text{SU}(2) \times \text{U}(1) \cong \text{U}(2) \). The resulting manifold of \( \text{SU}(3) \) coherent states is then isomorphic to the coset space \( \text{SU}(3)/\text{U}(2) \cong S^2 / S^1 \cong \text{CP}^2 \). Note that the dimension of this manifold is \( 8 - 4 = 4 \). In the fundamental representation, a generic \( \text{SU}(3) \) coherent state can be expressed as
\[ |\Omega(\theta, \phi, \alpha_1, \alpha_2)\rangle = R(\theta, \phi, \alpha_1, \alpha_2) |1\rangle \]
\[ = e^{i\alpha_1 \sin \theta \cos \phi} |1\rangle + e^{i\alpha_2 \sin \theta \sin \phi} |2\rangle + e^{i\alpha_3} |3\rangle, \quad (27) \]
where \( R(\theta, \phi, \alpha_1, \alpha_2) \in \text{SU}(3)/\text{U}(2) \), that takes the form\(^{48} \)
\[ \begin{pmatrix} \sin \theta \cos \phi & \sin \theta \sin \phi e^{i\alpha_1} & \cos \theta \\ \cos \theta \sin \phi e^{i\alpha_2} & \cos \theta \cos \phi & \sin \theta e^{-i\alpha_1} \\ - \sin \theta & 0 & 0 \end{pmatrix}. \]
A general \( \text{SU}(N) \) coherent state with \( N > 3 \) can be constructed by a straightforward generalization of the procedure that we used for the \( \text{SU}(2) \) and \( \text{SU}(3) \) cases:
\[ |\Omega(\{p_i\})\rangle = \hat{\Omega}(\{p_i\})|\mu\rangle, \quad (29) \]
where \( \hat{\Omega}(\{p_i\}) \in \text{SU}(N)/I \) with \( I = \text{SU}(N-1) \times \text{U}(1) \cong \text{U}(N-1) \). The \( \text{SU}(N) \) coherent state, which is topologically equivalent to the complex projective space \( \text{CP}^{N-1} \), is then parameterized by \( N^2 - 1 - (N - 1)^2 = 2(N - 1) \) real parameters \( \{p_i\} \). The explicit forms of the \( \text{SU}(N) \) coherent states can be found in Ref.\(^{49} \) [in the spherical coordinates with \( 2(N - 1) \) real parameters] and in Ref.\(^{32} \) (in terms of \( N - 1 \) complex parameters). Similarly to the \( H_1 \) coherent states [see Eq.\((5)\)], the \( \text{SU}(N) \) coherent states form an over-complete basis of the Hilbert space of an \( N \)-level system. The overlap between two \( \text{SU}(N) \) coherent states and the corresponding integration measure over the parameters \( \{p_i\} \) can be found in Ref.\(^{49} \).

IV. CLASSICAL LIMIT FOR A SPIN SYSTEM BASED ON \( \text{SU}(N) \) COHERENT STATES

We have seen in Sec. II that the \( H_1 \) coherent states can be used to recover the classical mechanics \((h \to 0) \) limit of a point particle. In this section we will follow similar steps to obtain a classical limit of a quantum spin-\( S \) system, whose local Hilbert space has a dimension \( N = 2S + 1 \). The \( \text{SU}(N) \) group consists of all unitary basis transformations (with determinant equal to \( 1 \)) of an \( N \)-level quantum-mechanical system, coherent states of \( \text{SU}(N) \) provide a natural platform to define the classical limit of a spin system. However, as we mentioned previously, the traditional approach has always been to use \( \text{SU}(2) \) coherent states to define a classical limit of spin systems. While the \( \text{SU}(N) \) Lie group is not the only alternative, the purpose of this section is to introduce this alternative path towards a classical a limit and later illustrate the advantages of using Lie groups that are larger than \( \text{SU}(2) \).

As before, the first step of the process is to take the \( h \to 0 \) limit of the expectation value of a quantum operator in an \( \text{SU}(N) \) coherent state. We then start by considering as an example the classical limit of the physical spin operator \( \hat{S}^z \) in the highest-weight state of \( \text{SU}(2) \):
\[ \lim_{h \to 0} \langle S^z \rangle = |S|\langle S^z \rangle = |S| = \text{lim}_{h \to 0} h\hat{S}^z. \]
Note that we made \( h \) explicit in the above equation to indicate that the spin is an intrinsically quantum-mechanical object, i.e., the simple definition of the classical operator given in Eq.\((14)\) does not exist for \( \hat{S}^z \) in Eq.\((30)\). However, we can still obtain a non-trivial classical limit by simultaneously sending \( S = \lambda_1 / 2 \) to infinity and \( h \) to zero, while keeping the product finite. This simple procedure can be easily generalized to any quantum operator \( \hat{A} \), which is a polynomial function of the physical \( \text{SU}(N) \) generators. The classical limit of an operator is then defined by taking the expectation value on a coherent state
\[ a(\{p_i\}) = \langle \Omega(\{p_i\}) | \hat{A} \Omega(\{p_i\}) \rangle, \quad (31) \]
where \( \{p_i\} \) is the set of \( N - 1 \) complex parameters that parametrize the \( \text{SU}(N) \) coherent states, and simultaneously sending the eigenvalue \( \lambda_1 \) –degenerate representations of \( \text{SU}(N) \) to infinity.

The second step is to consider the classical limit of the expectation value of the product of two operators. We ought to prove that the factorization rule holds in the classical limit
\[ \langle \Omega(\{p_i\}) | \hat{A} \hat{B} \Omega(\{p_i\}) \rangle \xrightarrow{\text{classical limit}} a(\{p_i\})b(\{p_i\}). \]
Indeed, the factorization rule holds for $\lambda_1 \to \infty$. The explicit proof is provided in Appendix A for the SU(2) case. The general proof for SU(N) is non-trivial and can be found in Ref. [32]. The crucial observation is that two distinct SU(N) coherent states become orthogonal in the limit $\lambda_1 \to \infty$. As a result, one can expand the integral associated with the expectation value in a similar manner as in Eq. (11), but now in powers of $1/\lambda_1$. Finally, by expanding the expectation value of the commutator between two operators up to the first order in $1/\lambda_1$ and then sending $\lambda_1 \to \infty$, one can prove the generalization of Dirac’s conjecture applied to the orbit of the SU(N) coherent states

$$a(\{\alpha_\rho\}), b(\{\alpha_\rho\}) = \sum_{\mu, \nu} g^{\mu\nu} \left( \frac{\partial a}{\partial \alpha_\nu} \frac{\partial b}{\partial \alpha_\mu} - \frac{\partial a}{\partial \alpha_\mu} \frac{\partial b}{\partial \alpha_\nu} \right) = \lim_{\lambda_1 \to \infty} -i \lambda_1 \langle \Omega(\{\alpha_\rho\}) | [\hat{A}, \hat{B}] | \Omega(\{\alpha_\rho\}) \rangle,$$

where $g^{\mu\nu}$ is the Fubini-Study metric of CP$^{N-1}$ [50]. The Poisson bracket of SU(2) is derived in Appendix A and the general derivation for SU(N) is given in Ref. [32]. We want to point out that for practical purposes, it is not always necessary to know a priori the exact form of the Poisson bracket to obtain the classical equations of motion. In most cases, it is simpler to evaluate the right hand side of Eq. (33). Namely, Eq. (33) provides us with a simple recipe to derive the classical dynamics on the manifold of SU(N) coherent states. We will follow this recipe in the next section to write down the generalized classical equations of motion for a quantum spin system.

V. CLASSICAL EQUATIONS OF MOTION FOR SPINS

In the previous section we saw that the classical SU(N) dynamics of a quantum spin system becomes exact for $\lambda_1 \to \infty$. However, for most systems of interest, the dimension of the local Hilbert space is finite and $\lambda_1 = 1$, implying that the classical dynamics is just an approximation of the exact quantum dynamics. The big advantage of this approximation is that the numerical cost of the simulations drops from an exponential to a linear dependence in the number of spins. The mathematical procedure of taking the classical limit can be physically represented as building a large SU(N) spin by ferromagnetically coupling $M$ replicas of the original spin and then sending $M$ to infinity. By replacing the SU(N) representation $[\lambda_1, \ldots, 0]$ with $[M \lambda_1, \ldots, 0]$, the spin—originally a microscopic object—becomes a macroscopic entity. It is important to note that the “ferromagnetic” coupling between replicas corresponds to an SU(N) ferromagnetic Heisenberg interaction [26]. In other words, the difference between different classical limits of a given spin system [e.g. SU(2) and SU(N)] is dictated by the nature of the coupling between different replicas. This raises the question about which classical limit better approximates the exact quantum dynamics. As we will explain in this section, the short answer to this question is that the choice of SU(N) coherent states with $N = 2S + 1$ guarantees that the dynamics will capture all the coherent low-energy modes that can appear for a general Hamiltonian. To appreciate this important point, we first derive two different classical dynamics based on SU(2) and SU(3) coherent states for a common quantum spin Hamiltonian and then we provide the general recipe to derive the classical dynamics for SU(N) coherent states.

A. SU(2) and SU(3) Landau-Lifshitz dynamics

Consider the following $S = 1$ spin Hamiltonian

$$\hat{H} = \frac{1}{2} \sum_{r, \delta} \sum_{\alpha, \beta} J^\alpha_\delta S^\beta_r S^\alpha_{r+\delta} + D \sum_r (S^z_r)^2,$$  

where $J^\alpha_\delta$ is the exchange tensor on the bond $\delta$ and $D$ is the strength of a single-ion anisotropy term. This $S = 1$ system admits two classical limits: one based on SU(2) coherent states (second representation with $\lambda_1 = 2$) and another one based on the SU(3) coherent states (fundamental representation with $\lambda_1 = 1$ and $\lambda_2 = 0$).

We will first consider the SU(2) classical limit. The time evolution of the spin components [generators of SU(2)] is dictated by the Heisenberg equation of motion

$$\frac{d \hat{S}^\alpha_r}{dt} = \frac{i}{\hbar} \left[ \hat{S}^\alpha_r, \hat{H} \right] = \sum_\delta \sum_{\mu, \nu, \beta} J^\mu_\delta \epsilon^{\alpha\mu\beta} \hat{S}^\beta_r \hat{S}^\nu_{r+\delta} + D \sum_\beta \epsilon^{\alpha\beta\gamma} (\hat{S}^\beta_r \hat{S}^\gamma_r + \hat{S}^\gamma_r \hat{S}^\beta_r),$$

where $\epsilon^{\alpha\mu\beta}$ is the Levi-Civita symbol. The classical limit of the interaction term is given by

$$\hat{S}^\beta_r \hat{S}^\nu_{r+\delta} \to \langle \Omega | \hat{S}^\beta_r \hat{S}^\nu_{r+\delta} | \Omega \rangle = \langle \Omega_r | \hat{S}^\beta_r \hat{S}^\nu_{r+\delta} | \Omega_{r+\delta} \rangle = S^\nu_r S^\beta_{r+\delta}.$$  

where we assumed that the coherent state of this system is a direct product of local coherent states, i.e., $|\Omega\rangle = \otimes_r |\Omega_r\rangle$. Since the single-ion anisotropy term is quadratic in the spin operators, we must use the factorization rule given in Eq. (32), which is only exact in the classical limit

$$\hat{S}^\beta_r \hat{S}^\nu_r + \hat{S}^\nu_r \hat{S}^\beta_r \to \langle \Omega | \hat{S}^\beta_r \hat{S}^\nu_r + \hat{S}^\nu_r \hat{S}^\beta_r | \Omega_r \rangle \sim 2 S^\nu_r S^\beta_r.$$  

As for the left-hand-side of the HE, the classical limit simply gives

$$d \hat{S}^\alpha_r / dt \to \langle \Omega_r | d \hat{S}^\alpha_r / dt | \Omega_r \rangle = d S^\alpha_r / dt.$$  

Consequently, the resulting classical equation of motion for SU(2) coherent states takes the form

$$\frac{d S^\alpha_r}{dt} = \sum_\delta \sum_{\mu, \nu, \beta} J^\mu_\delta \epsilon^{\alpha\mu\beta} S^\beta_r S^\nu_{r+\delta} + 2 D \epsilon^{\alpha\beta\gamma} S^\beta_r S^\gamma_r.$$
which is the well-known Landau-Lifshitz (LL) equation without the damping term,
\[ \frac{ds_\nu}{dt} = \sum_{\mu \nu} e_{\alpha \mu \nu} \delta_r b_\nu, \quad b_r = -\frac{dh}{ds_r}, \tag{40} \]
where \( h = \langle \Omega | \hat{H} | \Omega \rangle \) is the classical Hamiltonian.

Let us consider now the classical limit based on SU(3) coherent states. In this case we need to compute the equation of motion of the eight generators of SU(3), \( \hat{O}_{1-8} \), which can be regarded as the components of the SU(3) spin. For this purpose, we are going to use the basis of generators given in Eq. (B1), which are obtained by applying an SU(3) transformation (change of basis) to the standard basis presented in Eq. (17). The advantage of the new “physical” basis is that it is a direct sum of bases of irreps of the SO(3) group of rotations. The first three elements, \( \hat{O}^{1-3} \), are the three spin operators \( \hat{S}^\mu \) which represent a local dipole moment and transform as vectors under rotations [three-dimensional irrep of SO(3)]. The last five elements of the basis, \( \hat{O}^{4-8} \), are symmetric and traceless bilinear forms in the spin operators that represent a nematic or quadrupolar moment [five-dimensional irrep of SO(3)]. Each irrep of SO(3) corresponds to a different multipole and the number of different irreps or multipoles for the more general SU(N) group is \( N - 1 \). Importantly, the equations of motion that dictate the dynamics of the different multipolar components are coupled. For instance, as we will see below, the dynamics of the dipolar generators of SU(3), \( \hat{O}^{1-3} \), is coupled to the dynamics of the nematic generators \( \hat{O}^{4-8} \). By adopting the SU(3) approach, we are treating the dipolar and the quadrupolar components on equal footing.

The first step is to rewrite the Hamiltonian in terms of the SU(3) generators:

\[ \hat{H} = \frac{1}{2} \sum_{\mu \nu} \sum_{i,j=1}^3 \hat{O}_i^{\mu} \hat{J}_r^{\nu} \hat{O}_r^{\mu} + \frac{D}{\sqrt{3}} \sum_{\nu} \left( \hat{O}_r^{\nu} + \frac{2}{\sqrt{3}} \right). \tag{41} \]

Note that the second term can be expressed in multiple ways. This ambiguity is removed by requiring that each Hamiltonian term must be linear in the SU(3) generators acting on a given site \( \mathbf{r} \) [note that the generators of SU(N) together with the identity form a complete basis for the complex vector space of \( N \times N \) matrices]. As shown in Eq. (B2), the quadrupolar components \( \hat{O}^{4-8} \) in general do not commute with the dipolar ones \( \hat{O}^{1-3} \). As a result, the eight Heisenberg equations of motion for the SU(3) spin components on each site turn out to be coupled:

\[ \frac{d\hat{O}_r^{\mu}}{dt} = \sum_{\alpha \beta} \sum_{i,j=1}^8 \hat{J}_r^{i \delta} f_{ij \delta} \hat{O}_i^{\beta} \hat{O}_r^{\beta} + \frac{D}{\sqrt{3}} \sum_{\nu} f_{\beta \gamma} \hat{O}_r^{\nu}, \tag{42} \]

Here \( i = 1 \ldots 8 \) and \( f_{ij \delta} \) are the structure constants of \( \text{su}(3) \) in the physical basis [see Eq. (B3) for the non-zero structure constants]. As with the SU(2) case, the classical limit of the interaction term is again obtained by assuming that the coherent state is a direct product of coherent states on each site. An important difference, however, is that the classical limit of the single-ion term does not require the use of the factorization rule, which can be a strong approximation for finite values of \( \lambda_1 \), because each term of Eq. (42) is now linear in the generators of SU(3) acting on a given site \( \mathbf{r} \). After taking the classical limit on the left-hand side of the above equation, we obtain the classical equations of motion for the SU(3) spins

\[ \frac{d\hat{o}_r^{\mu}}{dt} = \sum_{\alpha \beta} \sum_{i,j=1}^8 J_r^{i \delta} f_{ij \delta} \hat{o}_i^{\beta} \hat{o}_r^{\beta} + \frac{D}{\sqrt{3}} \sum_{\nu} f_{\beta \gamma} \hat{o}_r^{\nu}, \tag{43} \]

or

\[ \frac{d\hat{o}_r^{\mu}}{dt} = \sum_{\mu \nu} f_{\mu \nu} \hat{o}_r^{\nu}, \quad \hat{o}_r = -\frac{dh}{do_r}. \tag{44} \]

Eq. (44) can be regarded as a generalization of the LLD (40).

Clearly, the SU(3) approach becomes strictly necessary when the ground state of the Hamiltonian under consideration has some form of nematic ordering. \( \langle \hat{O}^{1-3} \rangle = 0 \) and \( \langle \hat{O}^{\nu} \rangle \neq 0 \) for some values of \( 4 \leq \nu \leq 8 \), which can either be spontaneous or induced by a large single-ion anisotropy term, such as the last term of \( \hat{H} \) for \( D \gg |\hat{J}_r^{i \delta}| \). The simple reason is that the SU(2) coherent states cannot describe a local quadrupolar moment. The need for the SU(3) dynamics becomes a bit more subtle when the ground state exhibits some form of magnetic (dipolar) ordering. Even in that case, nematic fluctuations can renormalize the magnitude of the dipole moment or produce coherent low-energy modes, which are different from the usual spin waves (dipolar fluctuations). These are the situations in which the SU(3) dynamics becomes more appropriate than the traditional SU(2) dynamics. In a few words, the SU(3) approach can faithfully represent all types of local fluctuations of a three-level system.

### B. SU(N) Landau-Lifshitz dynamics

The SU(2) LLD can be straightforwardly generalized to SU(N) spins by following the same steps that we described for the SU(3) case. The classical equations of motion are obtained by (i) expressing the Hamiltonian in terms of generators of SU(N) under the condition that each term must be linear in the SU(N) spin components acting on a given site, (ii) computing the Heisenberg equation of motion for each generator of SU(N), and (iii) replacing the operators with their expectation values for coherent states of SU(N).

Based on the above discussions, it is apparent that to faithfully describe all types of fluctuations in a spin-\( S \) system, whose classical phase space is isomorphic to \( \mathbb{CP}^{N-1} \), we need to take the classical limit based on SU(N) coherent states with \( N = 2S + 1 \). We note however that for particular spin Hamiltonians a subgroup of SU(N) may also provide a good approximation, as long as it incorporates the relevant components of the local order parameter. As an example, we can just consider the case of pure isotropic Heisenberg models, whose dynamics is well described by the traditional SU(2) LLD if the spin \( S \) is large enough. The key observation is that the local order parameter of these systems has a dominant dipolar character.
and the normal modes are coherent spin waves. Non-dipolar fluctuations can still be described as a continuum of multiple spin waves. In other words, the SU(2) dynamics breaks down when new normal modes associated with non-dipolar fluctuations emerge below the continuum of multiple spin waves.

VI. SINGLE-ION MODEL

Consider the following integer spin-$S$ single-ion Hamiltonian,

$$\hat{H}_S = D (\hat{S}^z)^2,$$  \hfill (45)$$

with $D > 0$. This term controls the high-temperature dynamics of the Hamiltonian given in Eq. (34) if $|D| \gg |J|$. The non-degenerate ground state of $\hat{H}_S$ is the eigenstate of $S^z$ with eigenvalue $m = 0$: $|m = 0\rangle$. The excited states are the doublets $|\pm m\rangle$ with $1 \leq m \leq S$. The exact quantum dynamics can be solved in a closed form as there is no interaction term in the Hamiltonian. The transverse dynamical spin structure factor can be computed by using the Lehmann representation:

$$S^+ (\omega) = \frac{1}{2\pi} \int_{-\infty}^{\infty} dt e^{i\omega t} \text{Tr} \left[ e^{-\beta \hat{H}_S} \hat{S}^+ (t) \hat{S}^- (0) \right],$$

where $\text{Tr}$ is the partition function. Similarly,

$$S^\pm (\omega) = \frac{1}{2\pi} \int_{-\infty}^{\infty} dt e^{i\omega t} \text{Tr} \left[ e^{-\beta \hat{H}_S} \hat{S}^\pm (t) \right] = \frac{1}{\beta} \frac{\partial Z}{\partial \omega} \delta (\omega).$$ \hfill (48)$$

The solution is given by

$$s^+ (t) = s^+ (0) e^{i\omega t}, \quad s^- (t) = s^- (0) e^{-i\omega t}, \quad s^z (t) = s^z (0),$$ \hfill (50)$$

with $\omega = \pm 2SD_s (0)$. The corresponding transverse dynamical spin structure factor is computed by performing a thermal average over initial SU(2) coherent states (see Appendix C for details), which reads

$$S^+_{SU(2)} (\omega) = \frac{S^z \sqrt{\beta D} \left( 1 - \frac{e^{-\beta \omega_0^2}}{2D\omega_0} \right) e^{-\beta S^2_0}}{2D \sqrt{\pi \text{erf} (\sqrt{\beta D S})}} \Theta (2DS - |\omega|)$$

$$= S^+_{SU(2)} (\omega),$$ \hfill (51)$$

where $\text{erf}(x)$ is the error function and $\Theta(x)$ is the Heaviside step function. Similarly,

$$S^\pm_{SU(2)} (\omega) = \left[ 1 - \frac{e^{-\beta \omega^2}}{2D\omega} \right] e^{-\beta S^2_0} \Theta (2DS - |\omega|) \right],$$

$$= S^\pm_{SU(2)} (\omega),$$ \hfill (52)$$

where $\alpha = \beta D S^2$.

Figure (1) shows a comparison between the exact result for the transverse dynamical spin structure factor [see Eq. (46)] and the SU(2) classical approximation given in Eq. (51) for three different spin values. Clearly, the quantum mechanical spectrum consists of discrete absorption peaks corresponding to $\Delta S^z = 1$ (for $\omega > 0$) transitions between discrete energy levels, whereas the SU(2) classical theory produces a broad continuum of spectral weight centered around $\omega = 0$. The continuous character of the distribution arises from the dependence of the spin precession frequency on the conserved quantity, $s^z (t) = s^z (0)$, which has a continuous distribution on the orbit of the SU(2) coherent states. For small values of $S$, such as $S = 1$, the classical result based on SU(2) coherent states deviates strongly from the exact quantum mechanical result [see Figs. (1)(a) and 1(b)]. Only for very large values of $S$ [see Fig. (1)(c) for $S = 1000$] the SU(2) classical result becomes a good approximation. The slow convergence of the quantum mechanical result to the large-$S$ limit demonstrates the need of implementing an alternative classical limit for realistic Hamiltonians, such as $\hat{H}_S$.

To illustrate the ideas discussed in Sec. VA, we now consider the classical limit of the single-ion model based on SU(3) coherent states as an approximation for the extreme $S = 1$ case. The generalized SU(3) LL equations take the form

$$\frac{do_1}{dt} = Do_5, \quad \frac{do_2}{dt} = -Do_4, \quad \frac{do_4}{dt} = Do_2, \quad \frac{do_5}{dt} = -Do_1,$$ \hfill (53)$$

$$\frac{do_3}{dt} = \frac{do_6}{dt} = \frac{do_7}{dt} = \frac{do_8}{dt} = 0.$$ \hfill (54)$$

The solution gives the time evolution of the classical dipole operators

$$s^+ (t) = \frac{1}{2} [s^+ (0) + o_4 (0) - i o_5 (0)] e^{iDt},$$

$$s^- (t) = \frac{1}{2} [s^- (0) + o_4 (0) + i o_5 (0)] e^{-iDt},$$ \hfill (55)$$

where $s^+ = o_1 \pm i o_2$, and

$$s^z (t) = s^z (0) = o_3 (0)$$ \hfill (56)$$

is a conserved quantity. By computing the thermal average over initial SU(3) coherent states of the Fourier transform of the spin-spin correlation function, we obtain the dynamical spin structure factor for $\omega \geq 0$:

$$S^+_{SU(3)} (\omega) = \delta (\omega, D) \frac{6 + 2e^{BD} (\beta D - 3) + \beta D (\beta D + 4)}{\beta^2 D^2 (e^{BD} - \beta D - 1)}$$

$$= S^+_{SU(3)} (\omega),$$ \hfill (57)$$
The values of the dynamical structure factor are normalized to the maximum intensity of the exact result.

\[ O^{ij}(\omega) = \frac{1}{2\pi Z} \int_{-\infty}^{\infty} dt e^{i\omega t} \text{Tr} \left[ e^{-\beta H} \hat{O}^j(t) \hat{O}^i(0) \right]. \]  

A similar renormalization factor \( s_r \rightarrow \sqrt{1 + 1/S_0^2} \) must be applied to the classical spins obtained from SU(2) coherent states to fulfill the sum rule in the infinite temperature limit \([51]\). In general, the renormalization factor that must be applied to recover the sum rule for arbitrary values of \( N \) and \( \lambda_1 \) is:

\[ \kappa(N, \lambda_1) = \frac{\sqrt{C_1(N, \lambda_1)}}{\sqrt{(N-1)^2/(2N)\lambda_1}} = \sqrt{1 + N/\lambda_1} \]  

where \( C_1(N, \lambda_1) = (N-1)^3\lambda_1^2/(2N) + (N-1)^3\lambda_1/2 \) is the eigenvalue of the quadratic Casimir operator of SU(3) for the degenerate irrep \( [\lambda_1, 0, \ldots, 0] \) \([52]\).

In the low temperature limit, \( \beta DS^2 \rightarrow \infty \), the dynamics is controlled by the normal modes of the quadratic fluctuations around the minimum energy classical state. The intensity of each excited mode is proportional to \( T \) because of the equipartition theorem. The exact quantum mechanical result can be recovered by multiplying the classical dynamical spin structure factor by \( \beta \omega \), which is a well-known quantum-classical correspondence for the harmonic oscillator \([24, 51]\). Note also that the ground state of \( H_{\text{SU}} \) has no net dipole moment, \( \langle \hat{S} \rangle = 0 \), for \( D > 0 \). In other words, the state has only a net quadrupolar moment, implying that the orbit of SU(2) coherent states is not enough to represent the classical limit of this state. This is another clear indicator of the need of using a bigger Lie algebra to define a classical limit of \( H_{\text{SU}} \) that captures the qualitative aspects of the exact quantum mechanical solution.

In summary, the spin dynamics of \( H_{\text{SU}} \) is well approximated by a classical LLD based on SU(3) coherent states, but it is not well-described by the traditional SU(2) LLD. Assuming that \( |D| \) is comparable or bigger than \( z J \) (\( z \) is the coordination number and \( J \) is the characteristic energy scale of the exchange tensor), this statement holds true for the full Hamiltonian \( \hat{H} \) [see Eq. (34)] for two simple reasons. In the high-\( T \) limit, the dynamics of \( \hat{H} \) is well approximated by the dynamics
$\hat{H}_\text{SI}$. The basic role of the interaction term of $\hat{H}$ is to broaden the delta function shown in Fig. (2). In the low-$T$ limit, the ground state of $\hat{H}$ is a quantum paramagnet with no net dipolar moment for $D > 0$. As we already explained for the single-ion case, such a state has no classical counterpart within the orbit of SU(2) coherent states. We note that this statement remains true for the magnetically ordered state if the system is relatively close to the quantum critical point that divides this phase from the quantum paramagnet [42], implying that it is still necessary to use SU(3) coherent states to approximate the spin dynamics of the ordered magnet in the proximity of the QCP. Interestingly, this statement remains true for the easy-axis case $D < 0$ and $|D|$ comparable or bigger than $zJ$. In this limit, the ground state is an Ising-like magnetically ordered state, which definitely has classical counterpart in SU(2) coherent states. However, the low-energy modes of this classical ground state include quadrupolar fluctuations [41], which are not captured by the traditional SU(2) LLD.

VII. CONCLUSIONS

In this work we exploited the fact that an $N$-level quantum mechanical system admits more than one classical limit to generalize the LLD for spin systems. As it was noticed by Perelomov [6] and Gilmore [7], different classical limits can be obtained by introducing coherent states of different Lie algebras and generalizing Dirac’s conjecture. A spin $S$ Hamiltonian admits more than one classical limit because it can be expressed as a function of generators of different Lie algebras [34]. Traditionally, spin $S$ Hamiltonians are expressed as functions of the components of the physical spin, which are generators of SU(2) in the spin $S$ irrep. However, one can express the same Hamiltonian as a function of generators of SU($2S+1$) in the fundamental representation [34] and introduce a new classical limit based on coherent states of SU($2S+1$). While this is not the only alternative to the traditional classical limit of a spin $S$ system, it has multiple advantages that were discussed in the previous sections of this work.

A clear advantage is that the orbit of coherent states is maximized for SU($N$) if $N$ is the local dimension of the coherent state. Based on the variational principle, the “SU($N$) classical limit” provides the best estimation of the ground state energy in comparison with other classical limits. For the same reason, SU($N$) coherent states allow us to describe physical states with no net dipolar moment (they are characterized by higher order multipoles) and coherent fluctuations that change the relative magnitude of the different multi-polar moments (i.e. fluctuations that are different from physical rotations). A common example is provided by the longitudinal modes of ordered magnets that change the length of the dipole moment. For a spin one system, these modes correspond to SU(3) rotations that change the relative magnitudes of the dipolar and quadrupolar components [41, 42].

In general, the main advantage of introducing a classical limit to approximate the dynamics of interacting quantum spin systems is a huge reduction in computational cost. While the cost of computing the exact dynamics grows exponentially in the number of spins $N$, the cost of simulating the classical spin dynamics grows linearly in $N$. The only difference in computational cost between the two classical limits presented here is a prefactor $N^2 - 1$ associated with the number of generators of SU($N$) (there is one equation of motion for each generator). In view of the comparable computational cost and vast range of applications of the traditional LLD, we envision that the generalization proposed in this work will have an important impact on the modeling of large classes of magnets that either include a large single-ion anisotropy (e.g. crystall field splitting of $d$ and $f$-electron magnets) or consist of weakly-coupled multi-spin units (e.g. weakly coupled spin dimers, trimers or quadrumers). In this work we used an example of the first case to illustrate the need of introducing the SU($N$) classical limit. To understand why weakly coupled multi-spin units require a similar treatment, it is enough to consider the simplest case of weakly-coupled $S = 1/2$ dimers. The local Hilbert space has dimension four and the eigenstates of a single-dimer antiferromagnetic Heisenberg Hamiltonian are the singlet ground state and a triplet of degenerate excited states. Once again, SU(2) coherent states are not enough to describe the non-magnetic character of the singlet state. In contrast, SU(4) coherent states allow us to describe a quantum paramagnet, as well as a magnetically ordered state (induced by a strong enough inter-dimer coupling) with a strong reduction of the magnitude of the ordered moment. Moreover, the SU(4) classical LLD accounts for the $N-1 = 3$ excited triplon modes of the quantum paramagnet that become dispersive for finite inter-dimer coupling. Note that the classical limit that is obtained with SU(4) coherent states corresponds to the classical limit of the semi-classical expansion (or generalized spin wave theory) [39, 53] that is constructed with the bond operators introduced by Sachdev and Bhatt [54].

Appendix A: Expansion in SU(2) coherent states

Consider the expectation value of the product of two on-site operators $\hat{A}$ and $\hat{B}$ for an SU(2) coherent state,

$$
AB(\theta, \phi) = \langle \Omega(\theta, \phi) | \hat{A} \hat{B} | \Omega(\theta, \phi) \rangle \\
= \frac{2S+1}{4\pi} \int d\Omega' |\langle \Omega | \Omega' \rangle|^2 \frac{\langle \Omega | \hat{A} | \Omega' \rangle \langle \Omega | \hat{B} | \Omega' \rangle}{\langle \Omega' | \Omega' \rangle \langle \Omega | \Omega \rangle},
$$

(A1)
where we inserted the resolution of identity in terms of SU(2) coherent states, and
\[
\frac{2S+1}{4\pi} d\bar{\Omega} = \frac{2S+1}{4\pi} d\phi d\theta \sin \theta
\] (A2)
is the Haar measure of SU(2). The first term of the above integrand is the overlap between two SU(2) coherent states [26]
\[
|\langle \Omega | \Omega' \rangle |^2 = \left(1 + \frac{\bar{\Omega} \cdot \bar{\Omega}'}{2} \right)^{2S}.
\] (A3)
where \( \bar{\Omega} = (\sin \theta \cos \phi, \sin \theta \sin \phi, \cos \theta) \). In the large-S limit [recall that \( S = \lambda_1/2 \) for SU(2)], the overlap becomes arbitrarily small except for \( \bar{\Omega}' \approx \bar{\Omega} \), i.e. two different SU(2) coherent states become orthogonal to each other. The large value of \( S \) justifies a saddle-point approximation to evaluate the integral in Eq. (A1). After expanding the term \( \bar{\Omega} \cdot \bar{\Omega}' \) up to the quadratic order in \( \delta \gamma = (\gamma' - \gamma) \), where \( \gamma = \theta, \phi \),
\[
\bar{\Omega} \cdot \bar{\Omega}' = \cos \theta \cos(\theta + \delta \theta) + \cos(\delta \phi) \sin(\theta) \sin(\theta + \delta \theta)
= 1 - \frac{1}{2} (\delta \theta)^2 - \frac{1}{2} \sin^2 \theta (\delta \phi)^2 + O[(\delta \gamma)^3].
\] (A4)
we rewrite the square of the overlap as
\[
|\langle \Omega | \Omega' \rangle |^2 = e^{\ln |\langle \Omega | \Omega' \rangle |^2} \approx e^{2S \ln \left[1 - \frac{1}{2} (\delta \theta)^2 - \frac{1}{2} \sin^2 \theta (\delta \phi)^2\right]}
\approx e^{-S \left[(\delta \gamma)^2/2 \sin^2 \theta (\delta \phi)^2/2\right]},
\] (A5)
Since (for fixed \( \theta \) and \( \phi \)) the second factor and the third factor of the integrand in Eq. (A1) are analytical functions of the complex variables \( \alpha' = \sin \theta' \phi' + i \theta' \) and \( \alpha = \sin \theta' \phi' - i \theta' \), respectively, we can expand the two terms as we did in Eqs. (9) and (10).

\[
AB(\theta, \phi) \approx \frac{2S+1}{4\pi} \int_0^{2\pi} d\phi' \int_0^{\pi} d\theta' \sin \theta'
\times e^{-S \left[(\theta' - \theta)^2/2 \sin^2 \theta (\phi' - \phi)^2/2\right]}
\left[A(\theta, \phi) B(\theta, \phi) - i \frac{1}{2 S \sin \theta} \frac{\partial A}{\partial \theta} \frac{\partial B}{\partial \phi} - \frac{1}{2 S \sin \theta} \frac{\partial A}{\partial \phi} \frac{\partial B}{\partial \theta}
+ i \frac{1}{2} \frac{\partial A}{\partial \theta} \frac{\partial B}{\partial \theta} + \frac{\partial A}{\partial \phi} \frac{\partial B}{\partial \phi} \right] + O[(1/S)^2].
\] (A7)
where \( \mathcal{L} \) includes terms (up to quadratic order) that vanish after the integration. Since the width of the Gaussian goes to zero in the large-S limit, we can extend the integration limits to infinity and set \( \sin \theta' = \sin \theta \) to recover the familiar form of the Gaussian integration. In summary, we have
\[
AB(\theta, \phi) = A(\theta, \phi) B(\theta, \phi) (1 + 1/(2S))
- i \frac{1}{2 S \sin \theta} \left[\frac{\partial A}{\partial \theta} \frac{\partial B}{\partial \phi} - \frac{\partial A}{\partial \phi} \frac{\partial B}{\partial \theta}\right]
+ i \frac{1}{2 S \sin \theta} \left[\frac{\partial A}{\partial \theta} \frac{\partial B}{\partial \theta} + \frac{\partial A}{\partial \phi} \frac{\partial B}{\partial \phi}\right] + O[(1/S)^2].
\] (A8)

Note that \( \{ \phi \sin \theta, \theta \} = 1 \) implying that \( \phi \sin \theta \) and \( \theta \) play the role of canonical coordinate and momentum variables defined on the \( S^2 \approx \mathbb{C}P^1 \) manifold of SU(2) coherent states. Finally, the SU(2) L-L equation Eq. (40) takes the following form in terms of these spherical coordinates
\[
\frac{d \phi}{d \tau} = - \frac{1}{\sin \theta} \frac{\partial h}{\partial \theta} = \{ \phi, h \}_P
\]
\[
\frac{d \theta}{d \tau} = \frac{1}{\sin \theta} \frac{\partial h}{\partial \theta} = \{ \theta, h \}_P.
\] (A10)
where \( h \) is the classical Hamiltonian.

### Appendix B: Physical basis of generators of SU(3)

The “physical” basis of generators of SU(3) is obtained by applying the following transformation to the natural basis defined in Eq. (17):
\[
\hat{O}_1 = \hat{S}_x = \frac{1}{\sqrt{2}} (\hat{g}_{13} + \hat{g}_{31} + \hat{g}_{23} + \hat{g}_{32}),
\]
\[
\hat{O}_2 = \hat{S}_y = \frac{1}{\sqrt{2}} (\hat{g}_{13} + i \hat{g}_{31} + i \hat{g}_{23} - i \hat{g}_{32}),
\]
\[
\hat{O}_3 = \hat{S}_z = 2 \hat{A}_1,
\]
\[\hat{O}_4 = - (\hat{S}^x \hat{S}^z + \hat{S}^z \hat{S}^x) = \frac{1}{\sqrt{2}} (-\hat{g}_{13} - \hat{g}_{31} + \hat{g}_{23} + \hat{g}_{32}),\]
\[\hat{O}_5 = -(\hat{S}^y \hat{S}^z + \hat{S}^z \hat{S}^y) = \frac{1}{\sqrt{2}} (i\hat{g}_{13} - i\hat{g}_{31} + i\hat{g}_{23} - i\hat{g}_{32}),\]
\[\hat{O}_6 = (\hat{S}^x)^2 - (\hat{S}^y)^2 = (\hat{g}_{12} + \hat{g}_{21}),\]
\[\hat{O}_7 = \hat{S}^x \hat{S}^y + \hat{S}^y \hat{S}^x = -i(\hat{g}_{12} - \hat{g}_{21}),\]
\[\hat{O}_8 = \sqrt{3} (\hat{S}^z)^2 - \frac{2}{\sqrt{3}} = \frac{2}{\sqrt{3}} (\hat{H}_1 + 2\hat{H}_2),\]
\[\text{(B1)}\]

where \(\hat{O}_{1-3}\) are the three components of the vector known as dipole moment and \(\hat{O}_{4-8}\) are the five components of the quadrupolar moment, which is a symmetric traceless tensor of rank two. The commutation relations between the generators of SU(3) can be formally written as

\[\left[\hat{O}_a, \hat{O}_b\right] = i \sum_c f_{abc} \hat{O}_c, \quad a, b, c = 1, \ldots, 8,\]
\[\text{(B2)}\]

where the structure coefficients \(f_{abc}\) are completely anti-symmetric in the three indices, generalizing the Levi-Civita symbol of SU(2). The non-zero coefficients (with zero permutation) take the values

\[f_{123} = 1, \quad f_{147} = 1, \quad f_{156} = -1, \quad f_{158} = -\sqrt{3}, \quad f_{246} = -1, \quad f_{248} = \sqrt{3}, \quad f_{257} = -1, \quad f_{345} = 1, \quad f_{367} = 2.\]
\[\text{(B3)}\]

Appendix C: Correlation function in the classical limit

In this appendix we consider the transverse dynamical spin structure factor of the single-ion problem Eq. (45) to illustrate how to compute dynamical correlation functions in the classical limit based on SU(N) coherent states. The trace in Eq. (46) now runs over the CP\(^{N-1}\) orbit of SU(N) coherent states

\[S^{+}(-\omega) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} dt e^{i\omega t} \frac{1}{Z} \int \mathcal{D} \{\{\alpha_p\}\} e^{-\beta H} |\Omega[\{\alpha_p\}]\rangle e^{-\beta H^*} \langle \Omega[\{\alpha_p\}]|e^{-\beta H} \langle \hat{S}^+(t)\hat{S}^-(0)|\Omega[\{\alpha_p\}]\rangle,\]
\[\text{(C1)}\]

where \(\mathcal{D} \{\{\alpha_p\}\}\) is the integration measure that can be found in Ref. [49] and the partition function is

\[Z = \int \mathcal{D} \{\{\alpha_p\}\} |\Omega[\{\alpha_p\}]\rangle e^{-\beta H} \langle \Omega[\{\alpha_p\}]|e^{-\beta H} \langle \hat{S}^+(t)\hat{S}^-(0)|\Omega[\{\alpha_p\}]\rangle.\]
\[\text{(C2)}\]

By exploiting the factorization rule given in Eq. (32), which is valid in the classical limit, we obtain

\[S^{+}(-\omega) \approx \frac{1}{2\pi} \int_{-\infty}^{+\infty} dt e^{i\omega t} \frac{1}{Z} \int \mathcal{D} \{\{\alpha_p\}\} e^{-\beta H} |\Omega[\{\alpha_p\}]\rangle e^{-\beta H} \langle \hat{S}^+(t)\hat{S}^-(0)|\Omega[\{\alpha_p\}]\rangle,\]
\[\text{(C3)}\]

where \(h[\{\alpha_p\}] = \langle \Omega[\{\alpha_p\}]|\hat{H}|\Omega[\{\alpha_p\}]\rangle\) is the classical Hamiltonian and we used the convolution theorem along with the time translation symmetry of \(\hat{H}\). The quantity

\[s^+(\omega) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} dt e^{i\omega t} s^+(t)\]
\[\text{(C4)}\]

is the Fourier transform of the classical spin operator \(s^+(t)\) and \(s^-(\omega) = [s^+(\omega)]^*\). Note that Eq. (C3) provides the basis for numerical implementations of the traditional LLD (e.g. Refs. [20, 21, 24]): the trace over the SU(N) coherent states is usually computed by applying the Metropolis-Hastings Monte Carlo algorithm and \(T\) is a finite time much longer than any characteristic time of the system.
