EXPLICIT UNOBSTRUCTED PRIMES FOR MODULAR DEFORMATION PROBLEMS OF SQUAREFREE LEVEL

TOM WESTON

Dedicated to the memory of Arnold Ephraim Ross

Abstract. Let $f$ be a newform of weight at least 2 and squarefree level with Fourier coefficients in a number field $K$. We give explicit bounds, depending on congruences of $f$ with other newforms, on the set of primes $\lambda$ of $K$ for which the deformation problem associated to the mod $\lambda$ Galois representation of $f$ is obstructed. We include some explicit examples.

1. Introduction

Let $f$ be a newform of weight $k \geq 2$, level $N$, and character $\omega$. Let $K$ be the number field generated by the Fourier coefficients of $f$. For any prime $\lambda$ of $K$ Deligne has constructed a semisimple Galois representation $\overline{\rho}_{f,\lambda} : G_{\mathbb{Q},S \cup \{\ell\}} \to \text{GL}_2(k_\lambda)$ over the residue field $k_\lambda$ of $K$ at $\lambda$; here $G_{\mathbb{Q},S \cup \{\ell\}}$ is the Galois group of the maximal extension of $\mathbb{Q}$ unramified outside the set $S$ of places dividing $N\infty$ and the characteristic $\ell$ of $k_\lambda$. The representation $\overline{\rho}_{f,\lambda}$ is absolutely irreducible for almost all primes $\lambda$; we write $\text{Red}(f)$ for the set of $\lambda$ such that $\overline{\rho}_{f,\lambda}$ is not absolutely irreducible.

Following Mazur, we say that a prime $\lambda \notin \text{Red}(f)$ is an obstructed prime for $f$ if the cohomology group $H^2(G_{\mathbb{Q},S \cup \{\ell\}}, \text{ad } \overline{\rho}_{f,\lambda})$ of the adjoint representation of $\overline{\rho}_{f,\lambda}$ is non-zero. We write $\text{Obs}(f)$ for the set of such primes. The importance of this notion rests on the fact that for $\lambda \notin \text{Obs}(f) \cup \text{Red}(f)$, the universal deformation ring associated to $\overline{\rho}_{f,\lambda}$ is isomorphic to a power series ring in three variables over the Witt vectors of $k_\lambda$; see Section 2 for details.

It was shown in [15] that $\text{Obs}(f)$ is finite for $f$ of weight $k \geq 3$. In this paper we obtain an explicit bound on $\text{Obs}(f)$ in the case that the level $N$ of $f$ is squarefree. We state our result here only for $N \geq 1$; see Section 4.2 for the general statement (where we also allow $k = 2$ and $S$ non-minimal) and a partial converse.

**Theorem.** Assume that $k \geq 3$ and that $N > 1$ is squarefree. Let $M$ denote the conductor of the Dirichlet character $\omega$. Then

$$\text{Obs}(f) \subseteq \{ \lambda \mid \ell \leq k + 1 \text{ or } \ell \mid N\varphi(N) \prod_{p \mid M} (p + 1) \} \cup \text{Cong}(f)$$

with $\text{Cong}(f)$ the set of congruence primes for $f$ (as defined in Section 4.2) and $\varphi$ the Euler totient function.

Supported by an NSF postdoctoral fellowship.
We note that the set Cong(\(f\)) is computable using the results of \([13]\) and a tool such as \([12]\). It is not immediately clear to the author what form to expect the analogue of this result for to take for \(N\) not squarefree.

In Section 2 we give a brief review of deformation theory and use standard duality arguments to reduce the vanishing of \(H^2\(G_{\mathbb{Q},S}, \text{ad} \bar{\rho}_{f, \lambda}\)\) to the vanishing of certain local and global cohomology groups. The local groups are the subject of Section 3; the computations rest on some simple cases of the local Langlands correspondence. In Section 4.1 we use results of Hida (as refined in \([6]\)) to relate the global cohomology group to a certain Selmer group studied by Diamond, Flach, and Guo. The main results of the paper are proved in Section 4.2. We give several explicit examples in Section 3.

It is a pleasure to thank Matthias Flach, Elena Mantovan, Robert Pollack, and Ken Ribet for helpful conversations related to this paper.

**Notation.** If \(\rho : G \to \text{GL}_2 R\) is a representation of a group \(G\) over a ring \(R\), we write \(\text{ad} \rho : G \to \text{GL}_3 R\) for the adjoint representation of \(G\) on \(\text{End}(\rho)\) and \(\text{ad}^0 \rho : G \to \text{GL}_3 R\) for the kernel of the trace map from \(\text{ad} \rho\) to the trivial representation. If \(\rho : G \to \text{GL}_n R\) is any representation, we write \(H^i(G, \rho)\) for the cohomology group \(H^i(G, V_\rho)\) with \(V_\rho\) a free \(R\)-module of rank \(n\) with \(G\)-action via \(\rho\).

We write \(G_\mathbb{Q}\) for the absolute Galois group of \(\mathbb{Q}\). We fix now and forever embeddings \(\mathbb{Q} \hookrightarrow \bar{\mathbb{Q}}_p\) for each \(p\), yielding injections \(G_p \to G_\mathbb{Q}\) with \(G_p\) the absolute Galois group of \(\mathbb{Q}_p\). We write \(I_p\) for the inertia subgroup of \(G_p\). Let \(\varepsilon_\ell : G_\mathbb{Q} \to \mathbb{Z}_\ell^\times\) be the \(\ell\)-adic cyclotomic character and let \(\bar{\varepsilon}_\ell : G_\mathbb{Q} \to \mathbf{F}_\ell^\times\) be its reduction, the mod \(\ell\) Teichmüller character. If \(M\) is a \(\mathbb{Z}_\ell[G_\mathbb{Q}]\)-module, we write \(M(1)\) for its first Tate twist \(M \otimes_{\mathbb{Z}_\ell} \varepsilon_\ell\). If \(S\) is a set of places of \(\mathbb{Q}\) containing the infinite place, the expression \(\text{“}p \in S\text{”}\) is to be interpreted as \(\text{“}p \in S - \{\infty\}\text{”}\).

## 2. Obstructions

**2.1. Deformation theory.** In this section we review the fundamentals of the deformation theory of representations of profinite groups as in \([8]\). Let \(k\) be a finite field and let \(\mathcal{C}\) denote the category of local rings which are inverse limits of artinian local rings with residue field \(k\); a morphism \(A \to B\) in \(\mathcal{C}\) is a continuous local homomorphism inducing the identity map on residue fields. Note that any ring \(A\) in \(\mathcal{C}\) is canonically an algebra for the Witt vectors \(W(k)\) of \(k\).

Let \(G\) be a profinite group and fix an absolutely irreducible continuous representation

\[\bar{\rho} : G \to \text{GL}_n k\]

for some \(n \geq 1\). A lifting of \(\bar{\rho}\) to a ring \(A\) in \(\mathcal{C}\) is a continuous representation \(\rho : G \to \text{GL}_n A\) such that the composition

\[G \xrightarrow{\bar{\rho}} \text{GL}_n A \to \text{GL}_n k\]

is equal to \(\rho\). Two liftings \(\rho_1, \rho_2\) of \(\bar{\rho}\) are said to be strictly equivalent if there is a matrix \(M\) in the kernel of \(\text{GL}_n A \to \text{GL}_n k\) such that \(\rho_1 = M \cdot \rho_2 \cdot M^{-1}\).

A deformation of \(\bar{\rho}\) to \(A\) is a strict equivalence class of liftings. Let

\[D_{\bar{\rho}} : \mathcal{C} \to \text{Sets}\]

be the functor sending a ring \(A\) to the set of deformations of \(\bar{\rho}\) to \(A\). The deformation functor \(D_{\bar{\rho}}\) is representable by \([8]\ Section 1.2]; that is, there is a ring \(R_{\bar{\rho}}\) in \(\mathcal{C}\) (called
the universal deformation ring of \( \bar{\rho} \) and an isomorphism of functors

\[
D_{\bar{\rho}}(-) \cong \text{Hom}_C(R_{\bar{\rho}}, -).
\]

Note that via (2.1) the identity map on \( R_{\bar{\rho}} \) corresponds to a deformation

\[ \rho^{\text{univ}} : G \to \text{GL}_n R_{\bar{\rho}} \]

of \( \bar{\rho} \); this is the universal deformation of \( \bar{\rho} \), and the isomorphism (2.1) sends \( f : R_{\bar{\rho}} \to A \) to the deformation \( f \circ \rho^{\text{univ}} \) of \( \bar{\rho} \) to \( A \).

The next proposition gives the fundamental connection between the deformation problem \( D_{\bar{\rho}} \) and the cohomology groups \( H^i(G, \text{ad} \bar{\rho}) \). We say that \( D_{\bar{\rho}} \) is unobstructed if \( H^2(G, \text{ad} \bar{\rho}) = 0 \).

**Proposition 2.1.** Assume that \( H^i(G, \text{ad} \bar{\rho}) \) is finite-dimensional over \( k \) for each \( i \); set \( d = \dim_k H^1(G, \text{ad} \bar{\rho}) \). Then there exists a (non-canonical) surjection

\[
W(k)[[T_1, \ldots, T_d]] \twoheadrightarrow R_{\bar{\rho}}
\]

with kernel generated by at most \( \dim_k H^2(G, \text{ad} \bar{\rho}) \) elements. In particular, if \( D_{\bar{\rho}} \) is unobstructed, then (2.2) is an isomorphism.

**Proof.** This is proved in [9, Section 1.6]. The existence of the surjection (2.2) follows from an isomorphism

\[
D_{\bar{\rho}}(k[\epsilon]/\epsilon^2) \cong H^1(G, \text{ad} \bar{\rho})
\]

(sending a deformation \( \rho \) to the cocycle \( c_\rho \) such that \( \rho(g) = \bar{\rho}(g)(1 + \epsilon \cdot c_\rho(g)) \) for all \( g \in G \)) and the interpretation of these groups as the tangent space of \( R_{\bar{\rho}} \) via (2.1). The statement about the kernel \( J \) of (2.2) follows from an injection

\[ \text{Hom}(J, k) \hookrightarrow H^2(G, \text{ad} \bar{\rho}) \]

constructed using an obstruction two-cocycle measuring the failure of \( \rho^{\text{univ}} \) to lift via (2.2).

\( \square \)

The next lemma will be useful later in the paper.

**Lemma 2.2.** Let \( \bar{\rho} : G \to \text{GL}_2 k \) be continuous and absolutely irreducible and let \( \chi : G \to k^\times \) be a character of order at least 3. Then \( H^0(G, \chi \otimes \text{ad} \bar{\rho}) = 0 \).

**Proof.** If the image of \( \bar{\rho} \) is dihedral, then the \( G \)-representation \( \text{ad} \bar{\rho} \) is the sum of the trivial character, a quadratic character, and an irreducible two-dimensional representation of \( G \). If the image of \( \bar{\rho} \) is not dihedral, then \( \text{ad} \bar{\rho} \) is the sum of the trivial character and an irreducible three-dimensional representation of \( G \). In either case the lemma follows since \( \chi \) is neither trivial nor quadratic.

\( \square \)

### 2.2. Galois cohomology.

Let \( k \) be a finite field of odd characteristic \( \ell \). We now apply the discussion of the previous section to the case of a two-dimensional Galois representation over \( k \). Fix a finite set \( S \) of places of \( Q \) including \( \ell \) and the infinite place. Let \( Q_S \) denote the maximal extension of \( Q \) unramified outside \( S \); set \( G_{Q, S} := \text{Gal}(Q_S/Q) \). Let

\[ \bar{\rho} : G_{Q, S} \to \text{GL}_2 k \]

be continuous and absolutely irreducible. We assume further that \( \bar{\rho} \) is odd in the sense that the image of complex conjugation has distinct eigenvalues. In this section we study the cohomology groups \( H^i(G_{Q, S}, \text{ad} \bar{\rho}) \).
Lemma 2.3. Each cohomology group $H^i(G_{Q,S}, \text{ad} \bar{\rho})$ is finite-dimensional over $k$ and
\[ \dim_k H^1(G_{Q,S}, \text{ad} \bar{\rho}) - \dim_k H^2(G_{Q,S}, \text{ad} \bar{\rho}) = 3. \]

Proof. The first statement is [13, Corollary 4.15], while the second is a straightforward calculation using Tate’s global Euler characteristic formula as in [3, Section 1.10]. \qed

Corollary 2.4. If $H^2(G_{Q,S}, \text{ad} \bar{\rho}) = 0$, then the universal deformation ring $R_{\bar{\rho}}$ is (non-canonically) isomorphic to $W(k)[[T_1, T_2, T_3]]$.

We will use global duality theorems of Poitou and Tate to study $H^2(G_{Q,S}, \text{ad} \bar{\rho})$. For a $k[G_{Q,S}]$-module $M$, define
\[ \mathcal{H}^1(G_{Q,S}, M) := \ker(H^1(G_{Q,S}, M) \to \bigoplus_{p \in S} H^1(G_p, M)). \]

Lemma 2.5. One has
\[ \dim_k H^2(G_{Q,S}, \text{ad} \bar{\rho}) \leq \dim_k \mathcal{H}^1(G_{Q,S}, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}) + \sum_{p \in S} \dim_k H^0(G_p, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}) \]
with equality if $\ell \neq 3$.

Proof. The trace pairing $\text{ad} \bar{\rho} \otimes \text{ad} \bar{\rho} \to k$ identifies $\bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}$ with the Cartier dual of $\text{ad} \bar{\rho}$. Thus by [13, Theorem 4.10] there is an exact sequence
\[ 0 \to H^0(G_{Q,S}, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}) \to \bigoplus_{p \in S} H^0(G_p, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}) \to \]
\[ \text{Hom}(H^2(G_{Q,S}, \text{ad} \bar{\rho}), k) \to \mathcal{H}^1(G_{Q,S}, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}) \to 0. \]
Since $\bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho} = \bar{\varepsilon}_\ell \oplus (\bar{\varepsilon}_\ell \otimes \text{ad}^0 \bar{\rho})$ and $\mathcal{H}^1(G_{Q,S}, \bar{\varepsilon}_\ell)$ vanishes by [14, Lemma 10.6], the lemma follows from the exact sequence and Lemma 2.2. \qed

We will study the local terms $H^0(G_p, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho})$ in Section 3. The global term $\mathcal{H}^1(G_{Q,S}, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho})$ is difficult to control directly; instead we now relate it to a certain Selmer group, which in turn is often computable using the results of Section 1.1.

Fix a totally ramified extension $K$ of the field of fractions of $W(k)$. The ring of integers $\mathcal{O}$ of $K$ lies in $C$; we write $m$ for its maximal ideal. Let $\rho : G_{Q,S} \to \text{GL}_2 \mathcal{O}$ be a lifting of $\bar{\rho}$ to $\mathcal{O}$. Let $V_\rho$ (resp. $A_\rho$) denote a three-dimensional $K$-vector space (resp. $(K/\mathcal{O})^3$) endowed with a $G_{Q,S}$-action via $\text{ad}^0 \rho : G_{Q,S} \to \text{GL}_3 \mathcal{O}$.

Let $V$ (resp. $A$) denote either $V_\rho$ (resp. $A_\rho$) or else its Tate twist. For a prime $p$, define
\[ H^1_j(G_p, V) := \begin{cases} H^1(G_p/I_p, V|_{I_p}) & p \neq \ell; \\
\ker(H^1(G_p, V) \to H^1(G_p, V \otimes B_{\text{crys}})) & p = \ell; \end{cases} \]
regarded as a $K$-subspace of $H^1(G_p, V)$; here $B_{\text{crys}}$ is the crystalline period ring of Fontaine. Let $H^1_j(G_p, A)$ denote the image of $H^1_j(G_p, V)$ under the pushforward from $H^1(G_p, V)$ to $H^1(G_p, A)$. For $M$ denoting either of $V$ or $A$, the Selmer group of $M$ is defined by
\[ H^1_j(G_{Q,S}, M) := \{ c \in H^1(G_{Q,S}, M) ; c|_{G_p} \in H^1_j(G_p, M) \text{ for all } p \}. \]
Following [3 Section 7], we will also need a slight variant of this construction. Define

\[ H^1_w(G_p, A) := \begin{cases} H^1(G_p/I_p, A_{\ell^r}) & p \neq \ell; \\ H^1_1(G_\ell, A) & p = \ell; \end{cases} \]

\[ H^1_\emptyset(G_Q, A) := \{ c \in H^1(G_Q, A) : c|_{G_p} \in H^1_{w}(G_p, A) \text{ for all } p \}. \]

Clearly one has \( H^1_1(G_p, A) \subseteq H^1_w(G_p, A) \) for all \( p \), so that

\[ H^1_1(G_Q, A) \subseteq H^1_\emptyset(G_Q, A). \]

In fact, this inclusion is an equality if \( A_{\ell^r} \) is divisible for all \( p \neq \ell \).

**Lemma 2.6.** Assume that \( \ell > 3 \) and \( H^1_1(G_Q, V_\rho) = H^1_1(G_Q, V_\rho(1)) = 0 \). Then

\[ \dim k \Pi^1(G_{Q,S}, \bar{\varepsilon}_\ell \otimes \text{ad}^0 \rho) \leq \dim k H^1_\emptyset(G_{Q,S}, A_\rho)[m]. \]

**Proof.** Since \( \rho \) is a lifting of \( \bar{\rho} \), the \( k[G_{Q,S}]-\text{module} \ A_\rho(1)[m] \) is a realization of \( \bar{\varepsilon}_\ell \otimes \text{ad}^0 \bar{\rho} \). We thus obtain a natural map

\[ H^1(G_Q, \bar{\varepsilon}_\ell \otimes \text{ad}^0 \bar{\rho}) = H^1(G_Q, A_\rho(1)[m]) \to H^1(G_Q, A_\rho(1)) \]

which is injective by Lemma 2.4. The image of \( \Pi^1(G_{Q,S}, \bar{\varepsilon}_\ell \otimes \text{ad}^0 \bar{\rho}) \) under (2.4) is easily seen to lie in \( H^1_1(G_Q, A_\rho(1)) \), so that we obtain an injection

\[ \Pi^1(G_{Q,S}, \bar{\varepsilon}_\ell \otimes \text{ad}^0 \bar{\rho}) \hookrightarrow H^1_1(G_Q, A_\rho(1)). \]

By [3 Theorem 1], the latter group is (non-canonically) isomorphic to \( H^1_1(G_Q, A_\rho) \) (see [15 Proposition 2.2]); this also uses the assumption on the vanishing of the Selmer group of \( V_\rho \) and \( V_\rho(1) \). The lemma thus follows from (2.5) and (2.3).

**Remark 2.7.** The only difficulty in analyzing the failure of (2.3) to be an isomorphism on \( m \)-torsion is the determination of the image of the restriction map

\[ H^1_1(G_Q, A_\rho(1))[m] \to H^1_1(G_\ell, A_\rho(1))[m]. \]

Unfortunately, this question appears to be quite difficult in general.

### 3. Local invariants

Let \( f = \sum a_n q^n \) be a newform of weight \( k \geq 2 \), squarefree level \( N \), and character \( \omega \). Let \( K \) be the number field generated by the Fourier coefficients \( a_n \) of \( f \). For any prime \( \lambda \) of \( K \), Deligne has constructed a continuous \( \lambda \)-adic Galois representation

\[ \rho_{f,\lambda} : G_Q \to \text{GL}_2 K_\lambda. \]

This representation is unramified at \( p \nmid N\ell \) (with \( \ell \) the characteristic of the residue field \( k_\lambda \) of \( K_\lambda \)) and for such \( p \) the trace (resp. the determinant) of the image of an arithmetic Frobenius element \( \text{Frob}_p \) under \( \rho_{f,\lambda} \) is equal to \( a_p \) (resp. \( p^{k-1} \omega(p) \)).

As usual we identify \( \omega : (\mathbb{Z}/N\mathbb{Z})^\times \to \mu_{\varphi(N)} \) with a Galois character via the canonical isomorphism \( \text{Gal}(\mathbb{Q}(\mu_N)/\mathbb{Q}) \cong (\mathbb{Z}/N\mathbb{Z})^\times \); the determinant of \( \rho_{f,\lambda} \) is then \( \varepsilon_k^{-1} \omega \). Let \( M \) denote the conductor of \( \omega \) and let \( \omega_0 : (\mathbb{Z}/M\mathbb{Z})^\times \to \mu_{\varphi(M)} \) be the associated primitive Dirichlet character. Then \( \omega \) is ramified at \( p \) if and only if \( p \) divides \( M \), in which case the restriction of \( \omega \) to the inertia group \( I_p \) is a non-trivial character taking values in \( \mu_{p-1} \).
For the remainder of this section we fix a prime $\lambda$ of $K$ dividing a rational prime $\ell$. Let
\[ \tilde{\rho}_{f,\lambda} : G_{\mathcal{O}} \to \text{GL}_2 k_\lambda \]
be the semisimple reduction of $\rho_{f,\lambda}$; this is well-defined independent of any choice of integral model of $\rho_{f,\lambda}$. We are interested in the local invariants $H^0(G_p, \bar{\varepsilon}_\ell \otimes \text{ad} \tilde{\rho}_{f,\lambda})$ for all primes $p$. As
\[ \bar{\varepsilon}_\ell \otimes \text{ad} \tilde{\rho}_{f,\lambda} \cong \bar{\varepsilon}_\ell \oplus (\bar{\varepsilon}_\ell \otimes \text{ad}^0 \tilde{\rho}_{f,\lambda}) \]
and
\[ H^0(G_p, \bar{\varepsilon}_\ell) \neq 0 \iff p \equiv 1 \pmod{\ell}, \]
we will restrict our attention below to the case that $\ell$ does not divide $p - 1$ and to the study of $H^0(G_p, \bar{\varepsilon}_\ell \otimes \text{ad}^0 \tilde{\rho}_{f,\lambda})$.

In the analysis below we make use of the local Langlands correspondence and the compatibility results completed in [1]. Rather than review these results in detail, we will only recall the consequences we need; see [15] for more details and references.

3.1. $p \nmid N\ell$. Fix $\alpha_p, \beta_p \in \bar{K}$ with $\alpha_p + \beta_p = a_p$ and $\alpha_p \beta_p = p^{k-1} \omega(p)$. In this case, we have
\[ \rho_{f,\lambda}|_{G_p} \otimes \bar{k}_\lambda \cong \chi_1 \oplus \chi_2 \]
where the $\chi_i : G_p \to \bar{k}_\lambda^\times$ are unramified characters with
\[ \chi_1(\text{Frob}_p) = \alpha_p; \quad \chi_2(\text{Frob}_p) = \beta_p. \]
We write $\bar{\chi}_i : G_p \to \bar{k}_\lambda^\times$ for the reduction of $\chi_i$.

**Lemma 3.1.** Assume $p \nmid N\ell$ and $p \not\equiv 1 \pmod{\ell}$. Then $H^0(G_p, \bar{\varepsilon}_\ell \otimes \text{ad} \tilde{\rho}_{f,\lambda}) \neq 0$ if and only if $a_p^2 \equiv (p+1)^2 p^{k-2} \omega(p) \pmod{\lambda}$.

**Proof.** Since the existence of eigenvectors with $k_\lambda$-rational eigenvalues is invariant under base extension, the existence of $G_p$-invariants in $\bar{\varepsilon}_\ell \otimes \text{ad}^0 \tilde{\rho}_{f,\lambda}$ is equivalent to the existence of $G_p$-invariants in
\[ (\bar{\varepsilon}_\ell \otimes \text{ad}^0 \tilde{\rho}_{f,\lambda}|_{G_p}) \otimes \bar{k}_\lambda \cong \bar{\varepsilon}_\ell \oplus \bar{\varepsilon}_\ell \bar{\chi}_1 \bar{\chi}_2^{-1} \oplus \bar{\varepsilon}_\ell \bar{\chi}_1^{-1} \bar{\chi}_2. \]
As $p \not\equiv 1 \pmod{\ell}$, this has non-trivial $G_p$-invariants if and only if one of the characters $\bar{\varepsilon}_\ell \bar{\chi}_1 \bar{\chi}_2^{-1}$, $\bar{\varepsilon}_\ell \bar{\chi}_1^{-1} \bar{\chi}_2$ is trivial. By (3.1) this occurs if and only if
\[ \frac{\alpha_p}{\beta_p} \equiv p^{\ell+1} \pmod{\lambda}. \]
This in turn is equivalent to
\[ \frac{\alpha_p}{\beta_p} \equiv \frac{p + 1}{p} \equiv p^{\ell+1} \pmod{\lambda} \]
\[ \frac{(\alpha_p + \beta_p)^2}{\alpha_p \beta_p} \equiv \frac{(p+1)^2}{p} \pmod{\lambda} \]
\[ a_p^2 \equiv (p+1)^2 p^{k-2} \omega(p) \pmod{\lambda} \]
as claimed. \[\square\]
3.2. \( p \mid M, p \neq \ell \). In this case the \( p \)-component \( \pi_p \) of the automorphic representation associated to \( \rho \) has conductor 1 and ramified central character. It follows that \( \pi_p \) is a principal series representation associated to one ramified character and one unramified character. On the Galois side, this translates to

\[
\rho_{f,\lambda}|_{G_p} \otimes \bar{\kappa}_\lambda \cong \chi_1 \oplus \chi_2
\]

for continuous characters \( \chi_i : G_p \to \bar{K}_\lambda^\times \) with \( \chi_1 \) ramified and \( \chi_2 \) unramified. Since \( \rho_{f,\lambda}|_{G_p} \) has determinant \( \varepsilon_\ell^{k-1}\omega|_{G_p} \), we have \( \chi_1\chi_2 = \varepsilon_\ell^{k-1}\omega|_{G_p} \). In particular \( \chi_1|_{p} = \omega|_{p} \) is a non-trivial character taking values in \( \mu_{p-1} \). If \( p \neq 1 \) (mod \( \ell \)), then \( \mu_{p-1} \) injects into \( k_\lambda^\times \) and consequently the reduction \( \bar{\chi}_1 : G_p \to \bar{k}_\lambda^\times \) is still ramified at \( p \).

**Lemma 3.2.** Assume \( p \mid M, p \neq \ell \), and \( p \neq 1 \) (mod \( \ell \)). Then \( H^0(G_p, \tilde{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}_{f,\lambda}) = 0 \).

**Proof.** As in Lemma 3.1, it suffices to show that the two characters \( \tilde{\varepsilon}_\ell \bar{\chi}_1 \bar{\chi}_2, \bar{\varepsilon}_\ell \bar{\chi}_1^{-1} \bar{\chi}_2 \) are non-trivial. Since \( \tilde{\varepsilon}_\ell \) and \( \bar{\chi}_2 \) are unramified at \( p \) while \( \bar{\chi}_1 \) is ramified at \( p \), this is clear. \( \square \)

3.3. \( p \mid \frac{N}{M}, p \neq \ell \). In this case \( \pi_p \) has conductor 1 and unramified central character. It follows that \( \pi_p \) is the special representation associated to an unramified character. This means that there exists an unramified character \( \chi : G_p \to \bar{K}_\lambda^\times \) such that

\[
\rho_{f,\lambda}|_{G_p} \otimes \bar{\kappa}_\lambda \cong \begin{pmatrix} \varepsilon_\ell \chi & * \\ 0 & \chi \end{pmatrix}
\]

with the upper right corner ramified.

**Lemma 3.3.** Assume \( p \mid \frac{N}{M}, p \neq \ell \), and \( p^2 \neq 1 \) (mod \( \ell \)). Then \( H^0(G_p, \tilde{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}_{f,\lambda}) \neq 0 \) if and only if \( \bar{\rho}_{f,\lambda} \) is unramified at \( p \).

**Proof.** Since \( p^2 \neq 1 \) (mod \( \ell \)), by [4, Lemma 5.1] we have

\[
\bar{\rho}_{f,\lambda}|_{G_p} \otimes \bar{k}_\lambda \cong \begin{pmatrix} \varepsilon_\ell \bar{\chi} & \nu \\ 0 & \bar{\chi} \end{pmatrix}
\]

for some \( \nu : G_p \to \bar{\kappa}_\lambda \); in fact, one checks directly that \( \bar{\chi}^{-1}\nu \) is naturally an element of \( H^1(G_p, \bar{\kappa}_\lambda(1)) \). Since \( \tilde{\varepsilon}_\ell \) and \( \bar{\chi} \) are unramified, \( \bar{\rho}_{f,\lambda}|_{G_p} \) is unramified if and only if \( \bar{\chi}^{-1}\nu \) is unramified. However, since \( p \neq 1 \) (mod \( \ell \)) every non-zero element of \( H^1(G_p, \bar{\kappa}_\lambda(1)) \) is ramified. We conclude that \( \bar{\rho}_{f,\lambda}|_{G_p} \) is unramified if and only if it is semisimple. [3, Lemma 5.2] now completes the proof. \( \square \)

**Lemma 3.4.** Assume \( p \mid \frac{N}{M}, p \neq \ell \), \( p^2 \neq 1 \) (mod \( \ell \)), and \( \bar{\rho}_{f,\lambda} \) absolutely irreducible. Then \( H^0(G_p, \tilde{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}_{f,\lambda}) \neq 0 \) if and only if there exists a newform \( f' \), of weight \( k \) and level dividing \( \frac{N}{p} \), such that \( \bar{\rho}_{f,\lambda} \cong \bar{\rho}_{f',\lambda} \) for some prime \( \lambda \) of \( \mathcal{O} \) over \( \mathcal{O} \).

Here by \( \bar{\rho}_{f,\lambda} \) (resp. \( \bar{\rho}_{f',\lambda} \)) we mean \( \bar{\rho}_{f,\lambda} \otimes \bar{k}_\lambda \) (resp. \( \bar{\rho}_{f',\lambda'} \otimes \bar{k}'_{\lambda'} \)) with \( \lambda' \) the intersection of \( \lambda \) with the field \( K' \) of Fourier coefficients of \( f' \) and with \( k'_{\lambda'} \) the residue field of \( K' \) at \( \lambda' \).)

**Proof.** By [4 (B) of p. 221], the existence of such an \( f' \) is equivalent to \( \bar{\rho}_{f,\lambda} \) being unramified at \( p \). Thus the lemma follows from Lemma 3.3. \( \square \)
Remark 3.5. If one further assumes that \( p' \neq 1 \pmod{\ell} \) for all \( p' \) dividing \( N \), then the newform \( f' \) of Lemma 3.4 must have level a multiple of \( M \) and character lifting \( \omega_0 \), so that \( \lambda \) is a congruence prime for \( f \) of level dividing \( \frac{N}{p} \) in the terminology of Section 4.1. Indeed, \( \bar{\rho}_{f,\lambda} \) is isomorphic to \( \tilde{\rho}_{f,\lambda} \) and thus has determinant \( \bar{\omega}^{k-1} \); therefore the character \( \omega' \) of \( f' \) must have reduction equal to \( \bar{\omega} \). However, since \( p \neq 1 \pmod{\ell} \) for all \( p \) dividing \( N \), the only such characters of conductor dividing \( N \) are those which lift \( \omega_0 \). Thus \( f' \) must have level divisible by \( M \) and character lifting \( \omega_0 \), as claimed.

3.4. \( p = \ell, \ell \nmid N \). We now give some mild improvements on the results of [15, Section 4] on the vanishing of \( H^0(G_\ell, \bar{\xi}_\ell \otimes \text{ad} \tilde{\rho}_{f,\lambda}) \). Recall that \( f = \sum a_n q^n \) is said to be ordinary (resp. supersingular) at \( \lambda \) if \( v_{\lambda}(a_\ell) = 0 \) (resp. \( v_{\lambda}(a_\ell) > 0 \)), with \( v_{\lambda} \) the \( \lambda \)-adic valuation. If \( f \) is ordinary at \( \lambda \), then the semisimplification of \( \rho_{f,\lambda}|_{G_\ell} \otimes \bar{K}_\lambda \) is isomorphic to \( \bar{\xi}^{k-1} \otimes 1 \), while if \( f \) is supersingular at \( \lambda \), then \( \tilde{\rho}_{f,\lambda}|_{G_\ell} \) is absolutely irreducible. (This all follows from the discussion of [3], pp. 214–215, for example.)

Lemma 3.6. Assume \( \ell \nmid N \). If \( f \) is ordinary at \( \lambda \) and \( H^0(G_\ell, \bar{\xi}_\ell \otimes \text{ad} \tilde{\rho}_{f,\lambda}) \neq 0 \), then \( k \equiv 0, 2 \pmod{\ell - 1} \).

Proof. It suffices to prove the corresponding result for the \( I_\ell \)-invariants of the semisimplification of \( (\bar{\xi}_\ell \otimes \text{ad} \tilde{\rho}_{f,\lambda}) \otimes \bar{\lambda} \). By the above discussion this semisimplification is isomorphic to \( \bar{\xi}_\ell \otimes \bar{\xi}_\ell^{k} \otimes \bar{\xi}_\ell^{2-k} \).

Since \( \bar{\xi}_\ell \) has order \( \ell - 1 \), the lemma follows. \( \square \)

Note that the above lemma is vacuous in the case of weight 2.

Lemma 3.7. Assume \( \ell \nmid N \). If \( f \) is supersingular at \( \lambda \) and \( \ell > 3 \), then \( H^0(G_\ell, \bar{\xi}_\ell \otimes \text{ad} \tilde{\rho}_{f,\lambda}) = 0 \).

Proof. As \( \tilde{\rho}_{f,\lambda}|_{G_\ell} \) is absolutely irreducible, this is immediate from Lemma 2.2. \( \square \)

4. Global results

We continue with a newform \( f = \sum a_n q^n \) of weight \( k \), squarefree level \( N \), and character \( \omega \) of conductor \( M \) as in Section 3. Let \( \mathcal{O} \) be the ring of integers of the field \( K \) of Fourier coefficients of \( f \). For each prime \( \lambda \) of \( K \), let \( V_{\rho,\lambda} \) be a three-dimensional \( K_\lambda \)-vector space with \( G_\mathcal{Q} \)-action via \( \text{ad} \rho_{f,\lambda} \). Fix a \( G_\mathcal{Q} \)-stable \( \mathcal{O}_\lambda \)-lattice \( T_{\rho,\lambda} \) in \( V_{\rho,\lambda} \) and set \( A_{\rho,\lambda} := V_{\rho,\lambda}/T_{\rho,\lambda} \). In general the \( k_\lambda[G_\mathcal{Q}] \)-module \( A_{\rho,\lambda}[\lambda] \) need not agree with the semisimple reduction \( \tilde{\rho}_{f,\lambda} \); however, these two representations must be isomorphic when \( \tilde{\rho}_{f,\lambda} \) is absolutely irreducible, which is the only case we shall consider below.

4.1. Congruences and Selmer groups. The purpose of this section is to explain how the results of [15] (as refined in [3]) and [4] relate adjoint Selmer groups with congruences of modular forms. Let \( d \) be a divisor of \( N \) which is divisible by \( M \). We say that a prime \( \lambda \) of \( K \) is a congruence prime of level \( d \) for \( f \) if there exists a newform \( f' \) of weight \( k \) and level \( d \) such that:

1. \( f' \) has character lifting \( \omega_0 \);
2. \( f' \) is not a Galois conjugate of \( f \);
3. \( \tilde{\rho}_{f,\lambda} \cong \tilde{\rho}_{f',\lambda} \) for some prime \( \lambda \) of \( \mathcal{Q} \) above \( \lambda \).

...
Proposition 4.2. Let \( \lambda \) be a prime of \( K \) dividing a rational prime \( \ell \) not dividing \( N \). Assume that \( N > 1 \) and that \( \bar{\rho}_{f,\lambda} \) is ramified at some \( p \) dividing \( N \). If \( \bar{\rho}_{f,\lambda} \) is absolutely irreducible, then \( \bar{\rho}_{f,\lambda}|_{G_F} \) is absolutely irreducible as well, where \( F = \mathbb{Q}(\sqrt{(-1)^{(\ell-1)/2}}) \).

Proof. As in [3, Lemma 7.14], if \( \bar{\rho}_{f,\lambda}|_{G_F} \) is absolutely reducible, then \( \bar{\rho}_{f,\lambda} \) is induced from a character of \( G_F \). In particular, it follows that the conductor \( N' \) of \( \bar{\rho}_{f,\lambda} \) (in the sense of [3]) is a square. However, \( N' \) must also divide the level \( N \) of \( f \); since \( N' \) is non-trivial by hypothesis and \( N \) is squarefree, this is impossible. \( \square \)

**Proposition 4.2.** Let \( \lambda \) be a prime of \( K \) dividing the rational prime \( \ell \). Assume that:

1. \( \bar{\rho}_{f,\lambda} \) is absolutely irreducible;
2. \( \ell > k; \)
3. Either \( N > 1 \) or \( \ell \not| (2k-3)(2k-1); \)
4. \( \ell \not| N; \)
5. \( \ell \not| \varphi(N) \) (that is, \( p \not= 1 \) (mod \( \ell \)) for all \( p \mid N \));
6. \( \bar{\rho}_{f,\lambda} \) is ramified at \( p \) for all \( p \mid \frac{N}{\lambda}; \)

Then \( \mathcal{H}_1^f(GQ, A_{\rho,\lambda}) \neq 0 \) if and only if \( \lambda \in \text{Cong}_N(f) \).

Proof. Conditions [1]-[3] guarantee that \( A_{\rho,\lambda} \) is minimally ramified in the sense of [3, Section 4.1, Lemma 4.1] and [3, Section 6.4] for \( N = 1 \). Using [1], [2], [3], and Lemma [4, or 3, and 6, Lemma 7.14] for \( N = 1 \), we may apply [3, Theorem 7.15] to conclude that

\[
\text{length}_{\mathcal{O}_K} \mathcal{H}_1^f(GQ, A_{\rho,\lambda}) = v_\lambda(\eta_f^{\bar{\theta}});
\]

here \( \eta_f^{\bar{\theta}} \) is the fractional ideal of \( K \) defined in [3, Section 6.4] and \( v_\lambda \) is the \( \lambda \)-adic valuation.

By definition, the ideal \( \eta_f^{\bar{\theta}} \) is generated by the discriminant \( d(L_f(\mathcal{O}_K)) \) of [3, proof of Theorem 5], which in turn equals the square of the algebraic special value of the adjoint \( L \)-function of \( f \):

\[
d(L_f(\mathcal{O}_K)) = \frac{(W(f)\Gamma(1, ad f)\Lambda(1, ad f))}{\Omega(f, +)\Omega(f, -)}.
\]

(All of this is only true up to factors of primes violating [1, 2, 4, 5].) In particular, [3, Theorems 1 and 2], the latter condition is equivalent to the existence of a newform \( f' \) of weight \( k \) and level dividing \( N \), not Galois conjugate to \( f \), such that \( \bar{\rho}_{f',\bar{\lambda}} \cong \bar{\rho}_{f',\bar{\lambda}} \) for some prime \( \bar{\lambda} \) above \( \lambda \).

It remains to show that \( f' \) has level \( N \) and character \( \omega \). Since \( \bar{\rho}_{f',\bar{\lambda}} \) has determinant \( \bar{\epsilon}_f^{-1}\omega \) and \( \mu_{\epsilon(N)} \) injects into \( k_{\lambda}^{\bar{\lambda}} \) (by [3]), \( f' \) has level divisible by \( M \) and character lifting \( \omega_0 \). Hypothesis [4, 5] guarantees that \( \bar{\rho}_{f',\bar{\lambda}} \) is ramified at all \( p \mid \frac{N}{\lambda} \), as well, so that \( f' \) must in fact have level \( N \). \( \square \)
4.2. **Vanishing of cohomology.** Let $S$ be a finite set of places of $\mathbb{Q}$ containing all places dividing $N\infty$; let $N_S$ denote the product of all primes in $S$. Fix a prime $\lambda$ of $K$ dividing a rational prime $\ell$. We are now in a position to compute $H^2(G_{\mathbb{Q}, S\cup\{\ell\}}, \text{ad} \bar{\rho}_{f,\lambda})$.

**Theorem 4.3.** Assume that $\bar{\rho}_{f,\lambda}$ is absolutely irreducible and $\ell > 3$. If

$$H^2(G_{\mathbb{Q}, S\cup\{\ell\}}, \text{ad} \bar{\rho}_{f,\lambda}) \neq 0,$$

then one of the following holds:

1. $\ell \leq k$;
2. $\ell | N$;
3. $\ell | \varphi(N_S)$;
4. $\ell | p + 1$ for some $p | \frac{N}{M}$;
5. $a_p^2 \equiv (p + 1)^2p^{k-2}\omega(p) \pmod{\lambda}$ for some $p | \frac{N_S}{\ell'}, p \neq \ell$;
6. $\ell = k + 1$ and $f$ is ordinary at $\lambda$;
7. $k = 2$ and $a_2^2 \equiv \omega(\ell) \pmod{\lambda}$;
8. $N = 1$ and $\ell | (2k-3)(2k-1)$;
9. $\lambda \in \text{Cong}(f)$.

Using Lemma 2.5 and the results of Sections 3 and 4, the reader should have little difficulty in detecting the source of each of the conditions above. We shall nevertheless endeavor to give a complete proof.

**Proof.** If (4.3) holds, then Lemma 2.5 implies that either

$$H^0(G_{\mathbb{Q}}, \bar{\varepsilon}_{\ell} \otimes \text{ad} \bar{\rho}_{f,\lambda}) \neq 0$$

for some $p \in S \cup \{\ell\}$ or

$$\exists^1(G_{\mathbb{Q}, S}, \bar{\varepsilon}_{\ell} \otimes \text{ad} \bar{\rho}_{f,\lambda}) \neq 0.$$  

Suppose first that (4.4) holds for a prime $p \in S \cup \{\ell\}$; we may assume $\ell | N$ by (2). If $H^0(G_{\mathbb{Q}}, \bar{\varepsilon}_{\ell}) \neq 0$, then $\ell$ divides $p - 1$ which in turn divides $\varphi(N_S)$, so that (3) holds. We may thus assume that $p \neq 1 \pmod{\ell}$ and

$$H^0(G_{\mathbb{Q}}, \bar{\varepsilon}_{\ell} \otimes \text{ad}^0 \bar{\rho}_{f,\lambda}) \neq 0.$$  

By Lemma 3.2 we know that $p$ does not divide $M$. If $p$ divides $\frac{N}{M}$, then by Lemma 3.4 and Remark 3.3 one of (4) or (5) holds, while if $p$ does not divide $N\ell$, then Lemma 3.1 implies that (2) must hold. Finally, if $p = \ell$ and $k > 2$, then Lemmas 3.5 and 3.7 force (5) or (6) to hold; if $k = 2$, then Proposition 4.1 forces (6) to hold.

It remains to consider the case that (4.3) holds, (4.4) does not hold for any $p \in S \cup \{\ell\}$, and none of (3)–(8) hold. Then by [8, Theorem 8.2]

$$H^1_{\text{f}}(G_{\mathbb{Q}}, V_{f,\lambda}) = H^1_{\text{f}}(G_{\mathbb{Q}}, V_{f,\lambda}(1)) = 0.$$  

Lemma 2.6 and (4.3) thus imply that

$$H^3_{\text{f}}(G_{\mathbb{Q}}, A_{p,\lambda}) \neq 0.$$  

Since $H^3_{\text{f}}(G_{\mathbb{Q}}, \bar{\varepsilon}_{\ell} \otimes \text{ad} \bar{\rho}_{f,\lambda}) = 0$ for all $p$ dividing $\frac{N}{M}$, Lemma 3.3 implies that $\bar{\rho}_{f,\lambda}$ is ramified at all such $p$. Proposition 1.2 now applies to show that $\lambda \in \text{Cong}_{N}(f)$. Thus (9) holds, completing the proof. \qed
Corollary 4.4. If $\bar{\rho}_{f,\lambda}$ is absolutely irreducible, $\ell > 3$, and $\lambda$ does not satisfy (4), then
$$R_{\bar{\rho}_{f,\lambda}} \cong W(k_{\lambda})[[T_1, T_2, T_3]].$$

Proof. This follows immediately from Theorem 4.3 and Corollary 2.4.

We also obtain the following partial converse to Theorem 4.3.

Theorem 4.5. Assume that $\bar{\rho}_{f,\lambda}$ is absolutely irreducible. Suppose that $\ell > 3$ and one of the following holds:

1. $\ell \mid \varphi(N_S)$;
2. $a_p^2 \equiv (p + 1)^2 p^{k-2} \omega(p) \pmod{p}$ for some $p \mid \frac{N}{\lambda}$, $p \neq \ell$;
3. $\lambda$ is a congruence prime for $f$ of level dividing $\frac{N}{\lambda}$ for some $p \mid \frac{N}{\lambda}$, $p \mid p(p+1)$;
4. $k = 2$, $\ell \mid N$, and $a_p^2 \equiv \omega(\ell) \pmod{\ell}$.

Then $H^2(G_{Q,S',\ell}, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}_{f,\lambda}) \neq 0$.

Proof. By Lemma 2.3 it suffices to show that these conditions guarantee that $H^0(G_p, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}_{f,\lambda}) \neq 0$ for some $p \in S$. If (1) holds, then $H^0(G_p, \bar{\varepsilon}_\ell) \neq 0$ for some $p \in S$, so that this is clear. If (2) holds, then by Lemma 2.1 we have $H^0(G_p, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}_{f,\lambda}) \neq 0$. If (3) does not hold but (4) does hold, then Lemma 3.4 implies that $H^0(G_p, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}_{f,\lambda}) \neq 0$. Finally, if (4) holds, then the proof of [15, Proposition 4.4] shows that $H^0(G_{\ell}, \bar{\varepsilon}_\ell \otimes \text{ad} \bar{\rho}_{f,\lambda}) \neq 0$.

5. Examples

In this section we use the data of [12] to bound the obstructed primes for the deformation problems associated to a few specific modular forms. Of course, the most interesting aspect of these computations are the determination of congruences between newforms. Using [12] we can check such congruences on the $p^\text{th}$ Fourier coefficients for all $p < 1000$; by the results of [13] these checks are more than sufficient to prove that these congruences actually exist in our examples. We will not comment further on this issue.

For a modular form $f$, we let $\text{Red}(f)$ denote the set of primes $\lambda$ of $K$ such that $\bar{\rho}_{f,\lambda}$ is absolutely reducible. We recall the following well-known facts regarding $\text{Red}(f)$; see [3, Lemma 7.13] for example.

Lemma 5.1. Let $f = \sum a_n q^n$ be a newform of weight $k$ and level $N$ with coefficient field $K$. Let $\lambda$ be a prime of $K$ dividing a rational prime $\ell$. Suppose that $\lambda \in \text{Red}(f)$, so that
$$\bar{\rho}_{f,\lambda} \otimes \bar{k}_\lambda \cong \chi_1 \oplus \chi_2$$
for characters $\chi_1, \chi_2 : G_{Q} \to \bar{k}_\lambda^\times$. If $\ell$ does not divide $N$, then each $\chi_i$ has conductor dividing $N\ell$. If also $\ell > k$, then one of the $\chi_i$ has conductor dividing $N$, so that
$$a_p \equiv p^{k-1} + 1 \pmod{\lambda}$$
for all $p \equiv 1 \pmod{N}$.

In practice one uses the second condition to bound the set $\text{Red}(f)$ and the first condition to check each remaining $\lambda$ not dividing $N$. For a prime $\lambda$ dividing $N$, one can still check that $\bar{\rho}_{f,\lambda}$ is absolutely reducible, but it is much more difficult to show that $\bar{\rho}_{f,\lambda}$ is absolutely irreducible; we will make no attempt to deal with this case below.
For a finite set of places $S$ containing all places dividing $N\infty$, we let $\text{Obs}_S(f)$ denote the set of $\lambda / \in \text{Red}(f)$ such that
\[
H^2(G_{\mathbb{Q},S\cup\{\ell\}}, \varepsilon_\ell \otimes \text{ad} \bar{\rho}_{f,\lambda}) \neq 0,
\]
or equivalently such that the deformation problem associated to
\[
\bar{\rho}_{f,\lambda} : G_{\mathbb{Q},S\cup\{\ell\}} \to \text{GL}_2 k_\lambda
\]
is obstructed. We simply write $\text{Obs}(f)$ for $\text{Obs}_{\{p\mid N\infty\}}(f)$.

In the interests of space, we make the following notational conventions. Fix a quadratic extension $K$ of $\mathbb{Q}$ and let $p$ be a rational prime. If $p$ ramifies in $K$, then we simply write $p$ for the prime of $K$ above $p$. If $p$ splits, then we will write $p, \overline{p}$ for the two primes of $K$ above $p$, at least when it is not important to distinguish between them.

5.1. Weight 12, level 5, trivial character. There are three newforms of weight 12, level 5, and trivial character. The first has rational Fourier coefficients and $q$-expansion
\[
f_1 = q + 34q^2 - 792q^3 - 892q^4 + 3125q^5 - 26928q^6 - 17556q^7 + \cdots
\]
while the other two,
\[
f_2 = q + (-10 + 6\sqrt{151})q^2 + (-110 + 32\sqrt{151})q^3 + (3448 - 120\sqrt{151})q^4
\]
\[
- 3125q^5 + (30092 - 980\sqrt{151})q^6 + (28950 + 1056\sqrt{151})q^7 + \cdots
\]
and its Galois conjugate, have field of Fourier coefficients $\mathbb{Q}(\sqrt{151})$. Note that $\text{Obs}(f_2)$ is simply the set of conjugates of elements of $\text{Obs}(f_2)$, so that it suffices to study $f_1$ and $f_2$.

Using Lemma 5.1, one computes that:
\[
\text{Red}(f_1) = \{2, 5, 31\};
\]
\[
\text{Red}(f_2) = \{p_2, p_5, \overline{p}_5, (601, 358 + \sqrt{151})\}.
\]

We now consider congruences. By comparing Fourier coefficients, one sees that $f_1$ and $f_2$ are congruent modulo primes above 2 and 5:
\[
\text{Cong}_{<5}(f_1) = \{2, 5\};
\]
\[
\text{Cong}_{<5}(f_2) = \{p_2, (5, 1 + \sqrt{151})\}.
\]
The only possible proper congruences is with the unique newform
\[
\Delta = q - 24q^2 + 252q^3 - 1472q^4 + 4830q^5 - 6048q^6 - 16744q^7 + \cdots
\]
of weight 12 and level 1; one computes that:
\[
\text{Cong}_{<5}(f_1) = \{2, 29\};
\]
\[
\text{Cong}_{<5}(f_2) = \{p_2, (5, 4 + \sqrt{151}), (131, 46 + \sqrt{151})\}.
\]

Both $f_1$ and $f_2$ are ordinary at 13, so that by Theorems 4.3 and 4.4 we conclude that:
\[
\{29\} \subseteq \text{Obs}(f_1) \subseteq \{3, 7, 11, 13, 29\};
\]
\[
\{(131, 46 + \sqrt{151})\} \subseteq \text{Obs}(f_2) \subseteq \{p_3, \overline{p}_3, p_7, \overline{p}_7, (11), (13), (131, 46 + \sqrt{151})\}.
\]
5.2. **Weight 6, level 30, trivial character.** There are two newforms of weight 6, level 30, and trivial character, both with rational Fourier coefficients:

\[ f_1 = q + 4q^2 + 9q^3 - 16q^4 + 25q^5 + 36q^6 + 32q^7 - 192q^8 \]
\[ \quad - 162q^9 + 100q^{10} + 12q^{11} - 144q^{12} - 154q^{13} + \cdots \]

\[ f_2 = q - 4q^2 + 9q^3 - 16q^4 - 25q^5 - 36q^6 + 164q^7 + 192q^8 \]
\[ \quad - 162q^9 + 100q^{10} + 720q^{11} - 144q^{12} + 698q^{13} + \cdots \]

Using Lemma 5.1, one computes that:

\[ \text{Red}(f_1) = \{2, 3, 5\}; \]
\[ \{2, 3\} \subseteq \text{Red}(f_2) \subseteq \{2, 3, 5\}. \]

The newforms \( f_1 \) and \( f_2 \) have a congruence modulo 12 (remember that one only checks the Fourier coefficients with exponent prime to 30), so that:

\[ \text{Cong}_{30}(f_1) = \text{Cong}_{30}(f_2) = \{2, 3\}. \]

There are ten newforms of level dividing 30 and trivial character to consider for proper congruences. The most interesting occur for \( f_2 \): it has a congruence modulo 19 with the newform

\[ q + 7q^2 + 9q^3 + 17q^4 - 25q^5 + 63q^6 + 12q^7 - 105q^8 \]
\[ \quad - 162q^9 - 175q^{10} + 112q^{11} + 153q^{12} - 974q^{13} + \cdots \]

of level 15, and modulo 31 with the newform

\[ q - 4q^2 - 26q^3 - 16q^4 - 25q^5 + 104q^6 - 22q^7 + 192q^8 \]
\[ \quad + 433q^9 + 100q^{10} - 768q^{11} + 416q^{12} - 46q^{13} + \cdots \]

of level 10. In any event, one computes:

\[ \text{Cong}_{< 30}(f_1) = \{2, 3, 5\}; \quad \text{Cong}_{< 30}(f_2) = \{2, 3, 19, 31\}. \]

Both \( f_1 \) and \( f_2 \) are ordinary at 7, so that we conclude that:

\[ \text{Obs}(f_1) \subseteq \{7\}; \]
\[ \{19, 31\} \subseteq \text{Obs}(f_2) \subseteq \{5, 7, 19, 31\}. \]

To give an explicit example of an obstructed set, using (3) of Theorem 4.5 one finds that

\[ \text{Obs}_{\{2, 3, 5, 17, \infty\}}(f_1) = \{7\}. \]

5.3. **Weight 3, level 35, character of conductor 7.** There are four newforms of weight 3, level 35, and with quadratic character \( \omega : \langle \mathbb{Z}/35\mathbb{Z} \rangle^\times \to \{\pm 1\} \) the Legendre symbol \( \left( \frac{\cdot}{7} \right) \). All four are defined over \( \mathbb{Q}(\sqrt{-5}) \): two are

\[ f_1 = q - q^2 - 2\sqrt{-5}q^3 - 3q^4 - \sqrt{-5}q^5 + 2\sqrt{-5}q^6 + 7q^7 + \cdots \]

and its Galois conjugate while the other two are

\[ f_2 = q + 2q^2 + \sqrt{-5}q^3 - \sqrt{-5}q^5 + 2\sqrt{-5}q^6 - (2 + 3\sqrt{-5})q^7 + \cdots \]
and its Galois conjugate. As before, it suffices to study $f_1$ and $f_2$. Using Lemma 5.1, one finds that:

$$\{p_2, p_3, \overline{p}_3, p_5\} \subseteq \text{Red}(f_1) \subseteq \{p_2, p_3, p_5, p_7, \overline{p}_7\}$$
$$\{p_3, \overline{p}_3\} \subseteq \text{Red}(f_2) \subseteq \{p_3, p_5, p_7, \overline{p}_7\}.$$ 

The newforms $f_1$ and $f_2$ have a congruence modulo 3, while $f_1$ and $\overline{f}_2$ have no congruences; thus:

$$\text{Cong}_{35}(f_1) = \text{Cong}_{35}(f_2) = \{p_3, \overline{p}_3\}.$$ 

Since $\omega$ has conductor 7, the only proper congruences we need to check are with the unique newform

$$q - 3q^2 + 5q^4 - 7q^6 - 3q^8 - 9q^9 - 6q^{11} + \cdots$$

of weight 3, level 7, and character $(\cdot)$. One finds that:

$$\text{Cong}_{<35}(f_1) = \{p_2\};$$
$$\text{Cong}_{<35}(f_2) = \{p_5\}.$$ 

Theorem 4.3 allows us to conclude that:

$$\text{Obs}(f_1) \subseteq \{p_7, \overline{p}_7\}$$
$$\text{Obs}(f_2) \subseteq \{p_2, p_5, p_7, \overline{p}_7\}.$$
