Abstract

In general, geometries of Petrov type II do not admit symmetries in terms of Killing vectors or spinors. We introduce a weaker form of Killing equations which do admit solutions. In particular, there is an analog of the Penrose–Walker Killing spinor. Some of its properties, including associated conservation laws, are discussed. Perturbations of Petrov type II Einstein geometries in terms of a complex scalar Debye potential yield complex solutions to the linearized Einstein equations. The complex linearized Weyl tensor is shown to be half Petrov type N. The remaining curvature component on the algebraically special side is reduced to a first order differential operator acting on the potential.

Keywords: Petrov classification, linearized gravity, Killing spinor

1. Introduction

Many of the known exact solutions of the Einstein equations are algebraically special, i.e. there are repeated principal null directions (PNDs) of the Weyl tensor. In terms of the Petrov classification [22], such spacetimes are of Petrov type II or more special. A well studied class is

Petrov type D, with two repeated PNDs. The class of Petrov type D spacetimes is completely classified and contains the Kerr family of rotating, vacuum black holes. A remarkable property of vacuum spacetimes of Petrov type D is the existence of 'hidden symmetries', namely, appropriate generalizations of Killing vectors such as Killing tensors and conformal Killing–Yano tensors. Penrose and Walker have shown the existence of a valence 2 Killing spinor, from which one can obtain the above mentioned symmetries. Due to the Goldberg–Sachs theorem, the vacuum type D condition is equivalent to the existence of two independent null geodesic congruences that are shear-free. On the other hand, generic vacuum spacetimes of Petrov type II (i.e. with only one repeated PND) do not possess any symmetries or hidden symmetries. However they do admit a shear-free null geodesic congruence. In this paper we show that this fact can be used to define a weaker version of the Killing equations, and we show that they are solved by a generalization of the Penrose–Walker Killing spinor.

The construction of solutions to the field equations for linear spinning fields in terms of scalar, tensorial or spinorial potentials has a long history and has been widely studied. In the case of the Maxwell field, the main names associated to this procedure are Debye and Hertz. Although the usage in the literature is not consistent, see Stewart, we shall here refer to scalar potentials of the above mentioned type as Debye potentials. In this paper we focus on the spin-2 case, and consider the construction of solutions to the linearized Einstein equations on backgrounds of Petrov type II, in terms of Debye potentials. The analogous construction on backgrounds of Petrov type D, including the Schwarzschild and Kerr spacetimes has been widely studied, see e.g. [10, 17, 32], and plays an important role in the study of black hole perturbations[12, 18] and the self-force problem [8, 19]. The construction of solutions to the linearized Einstein equation by the Debye potential method on backgrounds of Petrov type II is possible and is closely analogous to the type D case. Kegeles and Cohen [17] and Stewart [29] have carried out a systematic study of the Debye potential construction in this case, and in particular, Stewart calculated the tetrad components of the linearized Weyl tensor. In this work we show that the linearized Weyl tensor is half type N.
is a Killing vector, i.e. a solution to the Killing equation
\[ \nabla (\omega \xi_b) = 0. \] (1.4)

In the Kerr-NUT class, from (1.1) one can also construct a Killing tensor \( H_{ab} \) and a second Killing vector \( \eta_a = H_{ab} \xi^b \), see [14] for details.

We now continue with the more general case of Petrov type II. Consider an Einstein space-time, i.e. the Einstein tensor being proportional to the metric or equivalently vacuum with cosmological constant, of Petrov type II. By [15], a spacetime with a Killing spinor of valence 2, cf equation (1.2), has Weyl tensor of type D, N or O, so a type II geometry does not admit a Killing spinor of valence 2. Instead, we prove in section 3 below:

**Theorem 1.** Let \((\mathcal{M}, g_{ab})\) be a real Einstein spacetime of Petrov type II, and let \( \alpha_A, \iota_A \) be a spin dyad, such that \( \alpha_A \) is a repeated principal spinor. Let \( \psi_i \) be the corresponding Weyl scalars. Define
\[ K_{AB} = \psi_2^{-1/3} \alpha(A) \iota_B - \frac{1}{3} \psi_2^{-4/3} \psi_3 \alpha_A \iota_B. \] (1.5)
\[ \xi_{AA'} = \nabla_{A'} K_{AB}. \] (1.6)

Then
(a) \( K_{AB} \) solves the ‘projected’ Killing spinor equation, cf (1.2),
\[ o^A \nabla_{A'} (K_{BC}) = 0. \] (1.7)
(b) \( \xi_{AA'} \) solves the ‘projected’ Killing equation, cf (1.4),
\[ o^A (\nabla_{AA'} \xi_{BB'} + \nabla_{BB'} \xi_{AA'}) = 0. \] (1.8)

It is outside the scope of this paper to analyze the solution spaces to the projected Killing equations, however see example 19 for solutions to (1.8) and section 3.1 for integrability conditions and their consequences for (1.7).

**Remark 2.** Introducing a Newman–Penrose null tetrad \((l^a, n^a, m^a, \bar{m}^a)\), see [21, 4.12] for details, define the complex tensors
\[ U_{ab} = \alpha_A \iota_B \epsilon_{A'B'} - l_a m_{b'} - m_{a'} l_{b}, \] (1.9)
\[ Y_{ab} = K_{AB} \epsilon_{A'B'}, \] (1.10)
\[ \xi_a = \nabla_b Y^b a, \] (1.11)
\[ Q_{abc} = \nabla_{(a} Y_{bc)} - \frac{1}{3} (g_{ab} \xi_c - \xi_{ab} \xi_{bc}) \] (1.12)

The conformal Killing–Yano equation is given by \( Q_{abc} = 0 \) and is equivalent to (1.2) (with the \( \xi \) removed). The projected Killing spinor equation (1.7) is equivalent to
\[ U_d^a Q_{abc} = 0. \] (1.13)
and the projected Killing equation (1.8) can be written in tensor form as
\[ U^e_a (\nabla_{ae} \xi_b + \nabla_b \xi_a) = 0. \] (1.14)

Also, the co-vector \( \xi_a \) given in (1.11) coincides with (1.6) and the solution (1.5) to the projected Killing spinor equation translates into
\[ Y_{ab} = \psi_{2}^{-1/3} (l_{\mu} n_{\delta} - m_{\mu} m_{\delta}) - \frac{1}{3} \psi_{2}^{-4/3} \psi_{4} U_{ab}. \] (1.15)

Now, the Debye potential construction [29] produces complex solutions to the linearized Einstein equations, which leads to the possibility of having ‘half types’ for the Weyl tensor. Recall first that in a real, four-dimensional orientable manifold with a metric of Lorentzian signature, the Hodge star operator * acting on two-forms satisfies \(*^2 = -1\), thus it has eigenvalues \(\pm i\). As a consequence, the eigenspaces of * are complex, i.e. a self-dual (SD) or anti-self-dual (ASD) two-form is necessarily complex. Any real two-form can be written as the sum of an SD part and an ASD part, and these pieces are complex conjugates of each other. Since the Weyl (ASD) two-form is necessarily complex. Any real two-form can be written as the sum of an SD piece and an ASD piece, where \(C_{abcd}\) and \(A_{abcd}\) are complex conjugates of each other. In spinor terms (see section 2 for notation and details), these are \(C_{abcd} = \bar{\psi}_{ABC} \epsilon_{A'B'C'D'}\) and \(A_{abcd} = \bar{\psi}_{ABC} \epsilon_{A'B'C'D'}\), where \(\bar{\psi}_{ABC}\) is the Weyl curvature spinor, see [21, section 4.6].

On the other hand, if the spacetime metric is complex, the above decomposition still holds, but the pieces \(C_{abcd}^+\) and \(C_{abcd}^-\) are now independent entities, so one has two independent Weyl spinors \(\psi_{ABCD}\) and \(\bar{\psi}_{ABCD}\)'s, see [22, section 6.9]. In particular, the Petrov types of \(\psi_{ABCD}\) and \(\bar{\psi}_{ABCD}\) are independent; for example, one part may be algebraically special while the other one is algebraically general.6 This also applies to linearized gravity, where even if the background metric is real, a complex perturbation will in general have independent SD and ASD linearized curvatures. In what follows we denote the SD and ASD linearized curvature spinors for a complex perturbation by \(\psi_{ABCD}\) and \(\bar{\psi}_{ABCD}\) respectively, see section 2 for details.

For compactness of notation, we shall make use of the Geroch–Held–Penrose (GHP) formalism [11]. For algebraically special spacetimes, the method of adjoint operators introduced by Wald in [32] (see section 4 for a brief review) can be used to show that if a scalar field \(\chi\) of GHP weight \(-4, 0\) solves the Debye equation

\[ \left( (\partial' - \partial^{'}) (\bar{\partial} + 3 \rho) - (\bar{\partial}' + \partial^{'}) (\bar{\partial} + 3 \tau) - 3 \bar{\psi}_{2} \right) \chi = 0, \] (1.16)

then the complex tensor field \(h_{ab} = S'(\chi)_{ab}\), where \(S'\) is the adjoint of the operator \(S\) defined in equation (4.3) below, is a solution to the linearized Einstein vacuum equations (possibly with cosmological constant). For perturbations of vacuum type D spacetimes, it was shown in [17] that the ASD linearized Weyl spinor \(\psi_{ABCD}\) has special algebraic structure, viz, it is of Petrov type N,

\[ \dot{\psi}_{ABCD} = o_{A} o_{B} o_{C} o_{D} \dot{\psi}_{4}, \] (1.17)

whereas the SD linearized Weyl spinor may be algebraically general.

Furthermore, while the linearized Weyl scalars associated to a Debye potential \(\dot{\chi}\) are given in general by fourth order differential operators applied to \(\dot{\chi}\), it was shown in [17], see also [3], that the scalar field \(\dot{\psi}_{4}\) in (1.17) is given by the simple expression,

\[ \dot{\psi}_{4} = cL_{\dot{\chi}} \dot{\chi}, \] (1.18)

with (possibly complex) constant \(c\). Here, \(L_{\dot{\chi}}\) is the Lie derivative along \(\dot{\chi}^\alpha\), which itself is given by (1.6) for the type D Killing spinor. In the Kerr spacetime, (1.18) is essentially the

6Note however that due to results by Rózga [26], in order for a complex four-dimensional spacetime to admit a real, Lorentzian slice, the algebraic type of \(\psi_{ABCD}\) and \(\bar{\psi}_{ABCD}\) must be the same. See also [34].
time derivative of $\dot{\chi}$, see also [18]. For Petrov type D, this reduction was done by Kegeles and Cohen [17] for the vacuum case and by Torres del Castillo [30] including a cosmological constant$^7$.

One may think that the remarkably simple structure (1.17) and (1.18) is associated to the very special symmetry properties of vacuum type D spacetimes, i.e. to the existence of the ‘hidden’ symmetry (1.1) and the two associated isometries mentioned before. In this note we generalize these results to Petrov type II spacetimes, which in general do not possess any isometries:

**Theorem 3.** Consider an Einstein spacetime of Petrov type II with repeated principal spinor $o^A$. Let $h_{ab}$ be a complex solution to the linearized Einstein vacuum equations generated by a Debye potential $\chi$. Then

(a) The ASD Weyl spinor of $h_{ab}$ is of Petrov type N,

$$\dot{\psi}_{ABCD} = o_A o_B o_C o_D \dot{\psi}_4. \quad (1.19)$$

(b) The non-vanishing component of (1.19) is given by

$$\dot{\psi}_4 = -\left(\psi_2^{4/3} \xi^a \Theta_a + 3\psi_2^2 + 6\psi_2 \Lambda\right) \chi. \quad (1.20)$$

Here $\xi^a$ is given by (1.6), where $K_{AB}$ is the projected Killing spinor (1.5), $\Theta_a$ is the GHP connection and $6\Lambda$ corresponds to the cosmological constant [21].

**Remark 4.** Upon finishing this work, we found a virtually unknown preprint by Jeffreys, [16], about half-algebraically special geometries and potentials for field equations. Although theorem 3 can alternatively be obtained from section 8 of that work, the interpretation of the derivative in terms of a projected Killing vector has not been given there. In fact the focus of that work was on the non-linear case coupled to Yang–Mills and the relation to the situation here is quite intricate, see remark 40 for further details.

In the case of linearized gravity in Minkowski spacetime, it was shown in [31] that real solutions of the linearized Einstein vacuum equations are in one-to-one correspondence with complex solutions with half-flat curvature, which in turn are in one-to-one correspondence with solutions of the scalar wave equation. The result of theorem 3 tells us that, while the complex metric perturbation generated by a Debye potential in a type II space is not half-flat, the linearized curvature has a simple structure since it is half type N.

For vacuum type D spacetimes, it is sometimes assumed that, up to gauge, all real solutions of the linearized Einstein vacuum equations can be obtained, locally, as the real part of a metric generated by a Debye potential; for recent advances in the Schwarzschild and Kerr cases see respectively [12, 23]. We also note the result by Ori, [20], on Kerr using separation of variables. For the more general vacuum type II case, from these considerations we expect the result of theorem 3 to be of relevance for addressing the following conjecture:

**Conjecture 1.** All real solutions of the linearized Einstein vacuum equations on a vacuum type II background can be locally obtained, up to gauge, as the real part of the metric generated by a Debye potential.

We also point out, that Jeffreys in [16] made remarks supporting the validity of this conjecture.

$^7$One of the authors, BW, also did this tedious computation including a cosmological constant in 1983, but did not publish it.
Remark 5. Metrics generated from a Debye potential are always in radiation gauge, as exemplified in lemma 29. It is known that any perturbation of Petrov type II geometries can be transformed into radiation gauge, see [24].

Theorem 3 generalizes the result (1.17) and (1.18) in the type D case to type II. We stress that a generic type II spacetime does not possess any ordinary or hidden symmetries, but only the more general objects (1.5) and (1.6) introduced in this work. While it can be shown that the ordinary, valence-2 Killing spinor equation is equivalent to the real, conformal Killing–Yano equation, which is itself a generalization to differential forms of the conformal Killing equation, for the ‘projected’ Killing spinor equation (1.7) no such equivalence exists. We will give a geometric interpretation to the origin of (1.7) in terms of spinors that are parallel under a suitable connection especially adapted to the geometry, which is the conformal-GHP connection. This also allows us to generalize the result (1.5)–(1.7) to non-vacuum spacetimes in the real-analytic case, and to derive conservation laws associated to projected Killing spinors in section 3.2.

In appendix A, we also review the Robinson–Trautman reduction of the Einstein equations which admits solutions of various Petrov types. In particular there is a Petrov type II solution which we use in example 19 to compute the projected Killing vector $\xi^a$.

Most computations were performed with Spinframes [2], based on the symbolic computer algebra package xAct for Mathematica.

2. Preliminaries

In this section, we review the two-spinor formalism, mention some distinctions in case the geometry is complex instead of real, and finally discuss a conformal GHP connection which plays an important role in the next section. The tensorial form of most equations used in this paper can be found in [21].

2.1. The two-spinor formalism

In this paper we shall make extensive use of the two-spinor formalism, following the notation and conventions in [21, 22]. The spinor bundles $S \rightarrow M$ and $S' \rightarrow M$ are rank-2 vector bundles with symplectic forms $\epsilon_{AB}$ and $\bar{\epsilon}_{A'B'}$, such that $T\mathcal{M} \otimes \mathbb{C} \cong S \otimes S'$ and $\epsilon_{ab} = \epsilon_{AB} \bar{\epsilon}^{AB}$.

The spaces of SD and ASD two-forms are written in spinor terms as $\Lambda^2_+ \cong S^* \otimes S'^*$ and $\Lambda^2_- \cong S^* \otimes S'^*$ (with $S^*$ the dual of $S$, etc); in other words, a real two-form $F_{ab} = F_{[ab]}$ has the spinor decomposition

$$F_{ab} = \phi_{AB} \epsilon_{A'B'} + \bar{\phi}_{A'B'} \epsilon_{AB},$$

where $F^+_{ab} = \bar{\phi}_{AB} \epsilon_{A'B'}$ and $F^-_{ab} = \phi_{A'B'} \epsilon_{AB}$ are the SD and ASD parts of $F_{ab}$ respectively, and $\phi_{AB} = \phi_{(AB)}$. The Riemann tensor admits a similar decomposition [21, equation (4.6.38)]:

$$R_{abcd} = \Psi_{ABCD} \epsilon_{A'B'} \bar{\epsilon}_{C'D'} + \bar{\Psi}_{AB'C'D'} \epsilon_{ABCD} + \Phi_{AB'C'D'} \epsilon_{A'B'} \epsilon_{CD} + \bar{\Phi}_{A'B'C'D'} \epsilon_{AB} \epsilon_{C'D'},$$

where $\psi_{ABCD} = \psi_{(ABCD)}$ is the Weyl conformal spinor, $\phi_{AB'C'D'} = \phi_{(AB'C'D')}$, is the trace-free Ricci spinor (which is real, i.e. $\bar{\phi}_{ab} = \phi_{ab}$), and $\Lambda = R/24$ represents the scalar curvature (which is also real, $\bar{\Lambda} = \Lambda$)\textsuperscript{8}.

---

\textsuperscript{8} In the Einstein case, we have $\phi_{AB'C'D'} = 0$ and cosmological constant $6\Lambda$. 

2.2. Self-duality

Let \((M,g_{ab})\) be a real, four-dimensional Lorentzian manifold. Throughout we make use of the abstract index notation. We assume the spacetime to be orientable so that there is a volume form \(\varepsilon_{abcd}\) and the associated Hodge star \(*: \Lambda^k \to \Lambda^{4-k}\), where \(\Lambda^k\) is the space of \(k\)-forms. For two-forms, \(*\) satisfies \(*^2 = -1\); this induces a decomposition \(\Lambda^2 = \Lambda_+^2 \oplus \Lambda_-^2\), where \(\Lambda_+^2\) (resp. \(\Lambda_-^2\)) is the rank 3 eigenbundle of \(*\) associated to the eigenvalue +i (resp. -i). Elements of \(\Lambda_+^2\) are called SD two-forms, and those of \(\Lambda_-^2\) are ASD two-forms. Since the Riemann curvature tensor has the symmetries \(R_{abcd} = R_{[ab][cd]}\), one can also apply the Hodge duality operation to it, in particular this defines the left- and right-dual Riemann tensors by \(*R_{abcd} = \frac{1}{2} \varepsilon^{ef}_{\ ab} R_{efcd}\) and \(R^*_{abcd} = \frac{1}{2} \varepsilon_{ef}_{\ ab} R_{defc}\), respectively. For the Weyl tensor, the left- and right-duals coincide: \(*C_{abcd} = C^*_{abcd}\). One then defines the SD and ASD Weyl tensors by

\[
C^\pm_{abcd} := \frac{1}{2} (C_{abcd} \mp i^* C_{abcd}).
\]

These tensors satisfy \(*C^\pm_{abcd} = \pm iC^\mp_{abcd}\).

In spinor terms, the SD and ASD Weyl tensors (2.3) are

\[
C^-_{abcd} = \psi_{ABCD} \bar{\epsilon}^{A'B'} \epsilon_{CD}, \quad C^+_{abcd} = \psi_{A'B'C'D'} \epsilon_{AB} \epsilon_{CD}.
\]

In particular, the SD and ASD Weyl tensors are complex conjugate of each other, which follows from (2.3).

2.3. Complex geometries

For complex geometries, as the above decompositions still apply, but now a pair of complex conjugate quantities that appear together in a real expression such as (2.1), is replaced by two independent entities; see [22, section 6.9]. For example, for a complex two-form, the conjugate quantities that appear together in a real expression such as (2.1), is replaced by \(\psi^*\bar{\psi}\), which is no longer the complex conjugate of \(\psi\bar{\psi}\). Similarly, the Riemann tensor of a complex metric has a spinor decomposition analogous to (2.2), but where \(\psi_{ABCD}\) is now replaced by another spinor \(\bar{\psi}_{A'B'C'D'}\) which is no longer the complex conjugate of \(\psi_{ABCD}\). The Ricci spinor \(\Phi_{ABCD}\) and the scalar curvature \(\Lambda\) do not acquire ‘tilded’ versions because of the original reality conditions \(\Phi_{ab} = \bar{\Phi}_{ab}\) and \(\bar{\Lambda} = \Lambda\), which are a consequence of the symmetries of the Riemann tensor; they simply become complex objects.

The fact that \(\psi_{ABCD}\) and \(\bar{\psi},\) are now two independent entities implies that one correspondingly has two independent algebraic classification schemes for the Weyl curvature spinors, so we can have for example conformally ‘half-flat’ manifolds if, say, \(\psi_{ABCD} = 0\) and \(\bar{\psi}_{A'B'C'D'} \neq 0\), or ‘half-algebraically special’ solutions if \(\psi_{ABCD}\) is algebraically special while \(\bar{\psi}_{A'B'C'D'}\) is general. These remarks about complex geometries apply of course also to complex, linear perturbations of real geometries.

2.4. Conformal-GHP connections

In section 3 we shall discuss some geometric aspects of projected Killing spinors. In order to do this we need an extension of the GHP derivative that includes conformal transformations. We call such an extension the ‘conformal-GHP’ connection, and give a brief review of some aspects of the construction that are relevant for this work.

Let \((M,g_{ab})\) be a Lorentzian spacetime, with Levi-Civita connection \(\nabla_{ab}\). Let \((o^A, \bar{\imath}^A)\) be a general spin dyad. We allow two kinds of transformations: (i) ‘GHP transformations’
\(o^A \rightarrow \gamma o^A, \quad \epsilon^A \rightarrow \gamma^{-1} \epsilon^A\), with \(\gamma\) a non-vanishing complex scalar field, and (ii) conformal transformations \(o^A \rightarrow o'^A, \quad \epsilon^A \rightarrow \Omega^{-1} \epsilon^A\), where \(\Omega\) is a positive scalar field. The transformation (ii) is induced by a transformation of the spin metric \(\epsilon^{AB} \rightarrow \Omega^{-1} \epsilon^{AB}\), which is in turn induced by a conformal transformation of the metric, \(g^{ab} \rightarrow \Omega^{-2} g^{ab}\).

Let \(S_{[pq]}[w]\) be the vector bundle of conformally weighted spinors with GHP weight \(\{p,q\}\) and conformal weight \(w\), and with an arbitrary index structure. This means that a section \(\varphi^A_{B,C} \in \Gamma(S_{[pq]}[w])\) transforms as \(\varphi^A_{B,C} \rightarrow \gamma^p \gamma^q \varphi^A_{B,C}\) under GHP transformations, and as \(\varphi^A_{B,C} \rightarrow \Omega^{\rho} \varphi^A_{\rho B,C}\) under conformal transformations. For example, we have \(\Omega^A \in \Gamma(S_{[1,0]}[0])\) and \(\epsilon^A \in \Gamma(S_{[-1,0]}[-1])\). The conformal-GHP covariant derivative is a linear connection \(\nabla_{AA'}^{\rho}_{\rho B,C} : \Gamma((S_{[pq]}[w]) \rightarrow \Gamma(T^* M \otimes S_{[pq]}[w])\). In this work all objects considered have vanishing \(q\)-weight, so we shall restrict to quantities of GHP weight \(\{p,0\}\). For the general case and more details see [5] and references therein. The action of \(\nabla_{AA'}^{\rho}_{\rho B,C}\) on, say, a spinor field \(\varphi^A_{B,C}\) with GHP weight \(\{p,0\}\) and conformal weight \(w\), is given by

\[
\nabla^{\rho}_{AA'}^{\mu}_{\mu B,C} = \nabla_{AA'}^{\rho}_{\rho B,C} + (w f_{AA'} + p(\omega_{AA'} + B_{AA'})) \varphi^A_{B,C} + \epsilon_{A'} \Gamma_{\rho}^{\rho}_{\rho B,C} + \epsilon_{A'} f_{AA'} \varphi^A_{B,C} - f_{CA'} \varphi^B_{C,A'} - f_{AC'} \varphi^B_{C,A'} - f_{AC'} \varphi^B_{C,A'},
\]

(2.5)

with

\[
\omega_{\rho} := -n_{\rho} + \ell_{\rho a} - \beta \gamma m_{\rho a} + \beta \gamma \bar{m}_{\rho a},
\]

(2.6)

\[
B_{\rho} := -\rho m_{\rho} + \tau m_{\rho},
\]

(2.7)

\[
f_{\rho a} := \rho m_{\rho a} + \beta \gamma \ell_{\rho a} - \tau \gamma m_{\rho a} - \tau \gamma \bar{m}_{\rho a},
\]

(2.8)

where we are using standard GHP notation for spin coefficients. For spinors with a different index structure, the corresponding action of \(\nabla_{AA'}^{\rho}_{\rho B,C}\) can be deduced from (2.5) by linearity and the Leibniz rule. By construction, the connection (2.5) is covariant under combined conformal and GHP transformations,

\[
\nabla^{\rho}_{AA'}^{\mu}_{\mu B,C} \rightarrow \gamma^p \Omega^q \nabla^{\rho}_{AA'}^{\mu}_{\mu B,C}.
\]

In particular, applying (2.5) to the spin frame \((o_A, \epsilon_A)\) and taking into account that \(o_A \in \Gamma(S_{[1,0]}[1])\) and \(\epsilon_A \in \Gamma(S_{[-1,0]}[0])\), one finds

\[
\nabla^{\rho}_{AA'}^{\mu}_{\mu B,C} = (\epsilon^A \partial^B \nabla_{AA'}^{\rho}_{\rho C,D}) o_{A'B},
\]

(2.9)

\[
\nabla^{\rho}_{AA'}^{\mu}_{\mu B,C} = (\epsilon^A \partial^B \nabla_{AA'}^{\rho}_{\rho C,D}) o_{A'B}.
\]

(2.10)

**Remark 6.** Analogously to the usual GHP connection, the conformal-GHP connection \(\nabla_{AA'}^{\rho}_{\rho B,C}\) depends on the choice of a spin dyad \((o^A, \epsilon^A)\). In what follows, the dyad \((o^A, \epsilon^A)\) will always be understood to be the one associated to \(\nabla_{AA'}^{\rho}_{\rho B,C}\).

### 3. Special geometry and parallel spinors

In this section we provide a geometric interpretation for projected Killing spinors and discuss general properties such as integrability conditions, the solution space and a relation to

---

9 When acting on scalar quantities, the projection of \(\nabla_{AA'}^{\rho}_{\rho B,C}\) on a null tetrad reduces to the conformally invariant GHP operators of Penrose and Rindler [21, equation (5.6.36)]. We note however that, for general spinors and tensors, the operators in [21, equation (5.6.36)] do not map conformal densities to conformal densities.
conservation laws. Except for some specific examples, we do not assume the geometry to be Ricci-flat. Several results below need a complexification of spacetime and in those situations we impose real-analyticity; this will be explicitly indicated in each case.

We will first show that the projected Killing spinor equation can be understood as a consequence of the existence of spinors that are parallel under the conformal-GHP connection.

Remark 7. The formulation in this section is conformally invariant (except for the specific examples in which we assume the Einstein condition, see (b) in lemma 13 and examples 18 and 23). This means that all results below are valid not only for a specific metric but for the equivalence class of metrics conformally related to each other, i.e. for conformal structures. For simplicity, however, we shall state the results in terms of spacetimes and not conformal structures.

Let \((\mathcal{M}, g_{ab})\) be a Lorentzian spacetime, and let \(o^A\) be a spinor field satisfying

\[
o^A o^B \nabla_{AA'} o_{A'} = 0. \tag{3.1}
\]

Such an \(o^A\) will be called a shear-free ray (SFR). If \(o^A\) is SFR, it follows from (2.9) that it is parallel under \(\mathcal{C}_{AA'}\). In GHP notation, (3.1) is equivalent to \(\kappa = \sigma = 0\). The condition \(\kappa = 0\) encodes that the null congruence associated to the vector field \(o^A \bar{o}^A\) is geodesic, whereas \(\sigma = 0\) states that this congruence is shear-free. Thus, a non-trivial solution to (3.1) imposes the existence of a shear-free null geodesic congruence.

Remark 8. Several results below require a complexified spacetime, for which we need to impose real-analyticity. The complex extension of \(\mathcal{M}\) will be denoted \(\mathcal{C}\mathcal{M}\). Our interest here is in the case where \(\mathcal{C}\mathcal{M}\) arises as the complexification of a real spacetime with Lorentzian signature, see [22, section 6.9].

The reason why we need to complexify \(\mathcal{M}\) is the following important result about SFRs:

**Lemma 9 (Proposition (7.3.18) in [22]).** Let \(o^A\) be a spinor, and let \(\mu^{A'}, \nu^{A'}\) be a primed spin dyad. Then the complex vector fields \(X^a = o^A \mu^{A'}\), \(Y^a = o^A \nu^{A'}\) on \(\mathcal{C}\mathcal{M}\) are in involution if and only if \(o^A\) is SFR.

Hence by Frobenius’ theorem, the distribution defined by \(\{X^a, Y^a\}\) is surface-forming in \(\mathcal{C}\mathcal{M}\). The surfaces associated to this distribution are complex, and they are called \(\beta\)-surfaces, see e.g. [22, pp 309–310]:

**Definition 10 (\(\beta\)-surface).** A \(\beta\)-surface is a complex two-dimensional surface in \(\mathcal{C}\mathcal{M}\) whose tangent vectors at any one point are all of the form \(o^A \mu^{A'}\) for some \(\mu^{A'}\), where \(o^A\) is fixed and satisfies equation (3.1).

For the following it is convenient to introduce some additional notation.

**Definition 11.** Let \(\mathcal{C}_{AA'}\) be the conformal-GHP connection associated to a spin dyad \((o^A, \epsilon^A)\). We define the operators

\[
\tilde{\mathcal{C}}_{A'} := o^A \mathcal{C}_{AA'}, \quad \mathcal{C}_A := \epsilon^A \mathcal{C}_{AA'}. \tag{3.2}
\]

It is worth discussing some properties of \(\tilde{\mathcal{C}}_{A'}\). It is a linear operator that satisfies the Leibniz rule, and which maps a section of \(\mathcal{S}_{(p,0)}[w]\) into a section of \(\mathcal{S}' \otimes \mathcal{S}_{(p+1,0)}[w]\), where \(\mathcal{S}'\) is the primed spin bundle introduced in section 2. Consider now a \(\beta\)-surface \(\Sigma\) in \(\mathcal{C}\mathcal{M}\). Any element of the tangent bundle \(T\Sigma\) is of the form \((x, o^A \mu^{A'})\), where \(x \in \Sigma\), \(o^A\) is fixed, and \(\mu^{A'}\) is some primed spinor at \(x\). Therefore we can identify \(T\Sigma\) with the restriction of the primed spin bundle to \(\Sigma\), \(\mathcal{S}'|_{\Sigma}\). Similarly, the cotangent bundle \(T^*\Sigma\) can be identified with the dual \(\mathcal{S}'^*|_{\Sigma}\).
This means that a primed spinor field $\psi_{A'}$ can be thought of as a ‘one-form’ in $T^*\Sigma$. Therefore, restricting to $\beta$-surfaces, the operator $\tilde{C}_{A'}$ is $\tilde{C}_{A'}: \Gamma(S_{(p,0)}[w]) \to \Gamma(T^*\Sigma \otimes S_{(p+1,0)}[w])$, from which we see that it can be regarded as a connection, in the usual sense, on conformally and GHP-weighted vector bundles over $\beta$-surfaces on $CM$, see [6].

We have the following result, which does not require analyticity:

**Lemma 12.** Let $(M, g_{ab})$ be a Lorentzian spacetime with $\tilde{C}_{A'}$ given by (3.2), where $\sigma^A$ satisfies (3.1). Then

$$[\tilde{C}_{A'}, \tilde{C}_{B'}] = 0$$

if and only if $\sigma^A$ is a repeated principal spinor of $\Psi_{ABCD}$, that is

$$\Psi_{ABCD} \sigma^B \sigma^C \sigma^D = 0.$$  

This result follows from lemmas 3.4 and 3.5 in [6]. As mentioned, the proof of lemma 12 does not require analyticity. However, from the discussion above we know that on $\beta$-surfaces, which live in $CM$, we can interpret $\tilde{C}_{A'}$ as a connection. In that case the commutator $[\tilde{C}_{A'}, \tilde{C}_{B'}]$ is the curvature of $\tilde{C}_{A'}$. Thus, the result of lemma 12 tells us that, as long as conditions (3.1) and (3.4) hold, $\tilde{C}_{A'}$ is a flat connection on $\beta$-surfaces. From [6, equation (3.27)] we see that one can associate a (twisted) de Rham complex to $\tilde{C}_{A'}$. Local exactness of a de Rham complex allows to find (local) potentials in specific situations; for example, we find the following:

**Lemma 13.** Suppose that $\sigma^A$ is SFR (3.1) and a repeated principal spinor (3.4).

1. Assume $(M, g_{ab})$ is real-analytic with complexification $CM$. Then there exist scalar fields $\phi$ and $\eta$ on $CM$, whose GHP and conformal weights are $\{0, 0\}$, $w = -1$ and $\{-2, 0\}$, respectively, such that $f_{A'}$, given in (2.8), takes the form

$$f_{AA'} = \nabla_{AA'} \log \phi - \sigma_A \tilde{C}_{A'} \eta.$$  

2. Assume that $(M, g_{ab})$ is real and that $g_{ab}$ is Einstein. Then, with Weyl scalars $\psi_i$, (3.5) holds for $\phi$ and $\eta$ given by

$$\phi = \psi_1^{1/3}, \quad \eta = \frac{1}{3} \psi_2^{-1} \psi_3.$$  

The proof of equation (3.5), along with other results and applications, will be given in a forthcoming publication. This proof involves the existence of $\beta$-surfaces and that is the reason why it is formulated in the real-analytic setting. On the other hand, (3.6) can be easily demonstrated in any Einstein spacetime, not necessarily analytic, by using the GHP form of the Bianchi identities.  

**Remark 14.** Consider the complexified spacetime $CM$.

- Since $\tilde{C}_{A'}$ is a flat connection, the equation $\tilde{C}_{A'} \lambda = 0$ has non-trivial solutions for any weights $\{p, 0\}$ and $w$. In particular, from (2.5) we see that, choosing $w = p = -1$, we have

$$0 = \tilde{C}_{A'} \lambda = \sigma^A \partial_{AA'} \lambda - \sigma^A \omega_{AA'} \lambda,$$

where we used that $\sigma^A f_{A'} = -\sigma^A B_{A'}$. It then follows that such $\lambda$ satisfies

$$\sigma^A \partial_{AA'} \log \lambda = \sigma^A \omega_{AA'}.$$  

10 Since the vacuum Bianchi identities are not conformally invariant, the expression (3.6) breaks conformal invariance.
Let \( \psi \) be a scalar field on \( \mathbb{C}M \) with GHP weight \( \{ p, 0 \} \) and conformal weight \( w \). Using (2.5), (3.5) and (3.8), we see that the action of \( \tilde{C}_A \) reduces to
\[
\tilde{C}_A \psi = \phi^{(w_p)} \lambda^p \partial^A [\phi^{(w_p)} \lambda^p \psi].
\] (3.9)

Using formula (3.9), it follows that if the weighted scalar field \( \psi \) satisfies \( \tilde{C}_A \psi = 0 \), then defining \( F = \phi^{(w_p)} \lambda^p \psi \), where \( \phi \) and \( \lambda \) are defined in (3.5) and (3.8) respectively, this is equivalent to
\[
\sigma^A \partial^A F = 0.
\] (3.10)

On \( \mathbb{C}M \), these functions are said to be ‘constant on \( \beta \)-surfaces’, since the operator \( \sigma^A \partial^A \) represents translations along the \( \beta \)-surfaces associated to \( \sigma^A \). That is to say, there exist linearly independent spinor fields \( \mu^A \), \( \nu^A \) such that \( \sigma^A \mu^A \partial^A \equiv \partial \tilde{z} \) and \( \sigma^A \nu^A \partial^A \equiv \partial \tilde{w} \), where \( \tilde{z}, \tilde{w} \) are coordinates along the \( \beta \)-surfaces. Then equation (3.10) can be interpreted as
\[
F = F(z, w),
\] (3.11)
where \( z, w \) are coordinates constant on each \( \beta \)-surface. Notice that (3.11) is a function on \( \mathbb{C}M \).

**Lemma 15.** Let \( \iota^A \) be any spinor field independent of \( \sigma^A \). Then the equation
\[
\iota^A \partial^A f = 0
\] (3.12)
has only constant functions as solutions.

**Proof.** To see this, note that if (3.12) holds we must also have \([\iota^A \nabla^A, \iota^B \nabla^B] f = 0\), but
\[
0 = [\iota^A \nabla^A, \iota^B \nabla^B] f = -\epsilon_{A'B'} (\iota^C \nabla^A \iota^B) \sigma^C \nabla_{C} f.
\] (3.13)

By definition we know that \( \iota^A \partial^A \iota^B = 0 \) if and only if \( \iota^A \) is SFR, but this is not the case since \( \iota^A \) is arbitrary, so we get \( \sigma^C \partial^C f = 0 \), which, when combined with (3.12), implies \( \nabla^A F = 0 \), i.e. \( F \) is constant. \( \square \)

In terms of this geometric setup, the projected Killing spinor equation can be deduced as follows:

**Proposition 16.** Let \( (\mathcal{M}, g_{ab}) \) be a Lorentzian spacetime. Let \( (\sigma_{A}, \iota_{A}) \) be the dyad associated to \( \mathcal{C}_{AA'} \) (cf remark 6), and suppose that \( \sigma_{A} \) is SFR.

(a) \( \sigma_{A} \) and \( \iota_{A} \) are parallel spinors for (3.2):
\[
\tilde{C}_A \sigma_B = 0, \quad \tilde{C}_A \iota_B = 0.
\] (3.14)

(b) Suppose in addition that \( (\mathcal{M}, g_{ab}) \) is real-analytic and that \( \iota_{A} \) is also a repeated principal spinor, so that equation (3.5) holds. Then the spinor field
\[
K_{AB} = \phi^{-1} [\sigma_{A} \sigma_{B} - \eta_{A} \sigma_{B}]
\] (3.15)
satisfies the projected Killing spinor equation,
\[
\sigma^A \nabla_{A}(K_{BC}) = 0.
\] (3.16)

The proof is given in appendix B.1.

**Remark 17.** Any spinor field of the form \( \omega_{A} = f \sigma_{A} \), where \( f \) is of type \( \{-1, 0\} \), \( w = 0 \), and satisfies \( \tilde{C}_A f = 0 \), is a solution to the ‘projected twistor equation’
\[
\sigma^A \nabla_{A} \omega_{B} = 0.
\] (3.17)
This follows from the identity $\sigma^A C_A(\omega_B) = \sigma^A \nabla_A(\omega_B)$ replacing $\omega_A = f o_A$.

From proposition 16 we have that the spinor field (3.15) is a projected Killing spinor in the general class of spacetimes where $o_A$ is SFR and a repeated PND but not necessarily Einstein, although in the non-Einstein case it must be real-analytic. This includes, in particular, the Kerr–(A)dS and (analytic) Kerr–Newman–(A)dS spacetimes, where $K_{AB}$ satisfies the usual, i.e. non-projected, Killing spinor equation.

**Example 18.** Suppose that $(\cal M, g_{ab})$ is Einstein, i.e. $g_{ab}$ satisfies the vacuum Einstein equations with cosmological constant. Then, using (3.6), we find that (3.15) reduces to the expression (1.5) given in the introduction. Furthermore, the vector field

$$\xi_{\AA'} = \nabla^\beta A\ K_{AB}$$

solve the projected Killing equation

$$\sigma^A (\nabla_{\AA'} \xi_{\BB'} + \nabla_{\BB'} \xi_{\AA'}) = 0.$$  

In GHP notation, (3.18) takes the form

$$\xi_a = \frac{3}{2\psi_2^2} \left( \rho I_a - \rho n_a + \tau' m_a + \tau m_a \right) + \frac{(\overline{\partial} - 4\sigma)\psi_3 m_a}{2\psi_2^3} m_a.$$  

and from the Bianchi identities it follows that

$$\xi^a \nabla_a \psi_2 = 0.$$  

Below we give two explicit examples. We review the Robinson–Trautman geometries in appendix A. There are known solutions of various Petrov types in this class and in particular there is one of Petrov type II.

**Example 19.**

- For the type II Robinson–Trautman solution given in (A.10), the vector (3.20) is of the form

$$\xi^a = -\frac{2(-1)^{2/3}}{3\sigma^{2/3}} \left( \frac{\zeta + \overline{\zeta}}{3} (\partial_r)^a + m(\partial_z)^a \right).$$  

We note that it does not reduce to $\partial_r$, which is a Killing vector of that solution.

- The Einstein metric given in equation (32) of [13] in coordinates $(r, \phi, z, t)$ leads to the projected Killing vector

$$\xi^a = \text{const. } (\partial_r)^a.$$  

This turns out to be one of the three Killing vectors of the metric.

### 3.1. Solutions to the projected Killing spinor equation

Let us now discuss the space of projected Killing spinors. In type D spacetimes one can show that the space of valence-2 Killing spinors (1.1) is one-dimensional, see e.g. [15]. For type II spacetimes, we first show the following:

**Proposition 20.** Let $(\cal M, g_{ab})$ be a Lorentzian spacetime, where $o^A$ is SFR and a repeated principal spinor. Let

$$K_{AB} = K_{2} o_A o_B - 2K_{1} o_{(A} k_{B)} + K_{0} o_{A} o_{B}$$  

where

$$K_{2} = K_{2} (\partial_r) o_{(A} o_{B)},$$  

$$K_{1} = K_{1} o_{(A} o_{B)}$$  

and

$$K_{0} = K_{0} (\partial_r) o_{(A} o_{B)}.$$  

Then

$$\sigma^A (\nabla_{\AA'} \xi_{\BB'} + \nabla_{\BB'} \xi_{\AA'}) = 0.$$  

and the projected Killing spinor equation can be written as

$$\sigma^A (\nabla_{\AA'} \xi_{\BB'} + \nabla_{\BB'} \xi_{\AA'}) = 0.$$  

From this, we have

$$\xi^a \nabla_a \psi_2 = 0.$$  

Below we give two explicit examples. We review the Robinson–Trautman geometries in appendix A. There are known solutions of various Petrov types in this class and in particular there is one of Petrov type II.

**Example 19.**

- For the type II Robinson–Trautman solution given in (A.10), the vector (3.20) is of the form

$$\xi^a = -\frac{2(-1)^{2/3}}{3\sigma^{2/3}} \left( \frac{\zeta + \overline{\zeta}}{3} (\partial_r)^a + m(\partial_z)^a \right).$$  

We note that it does not reduce to $\partial_r$, which is a Killing vector of that solution.

- The Einstein metric given in equation (32) of [13] in coordinates $(r, \phi, z, t)$ leads to the projected Killing vector

$$\xi^a = \text{const. } (\partial_r)^a.$$  

This turns out to be one of the three Killing vectors of the metric.
be a projected Killing spinor, i.e. solving (1.7). Then the components satisfy
\begin{align}
K_0 &= 0, \quad (3.25) \\
\tilde{\mathcal{C}}_A K_1 &= 0, \quad (3.26) \\
\tilde{\mathcal{C}}_A K_2 + 2C_A K_1 &= 0. \quad (3.27)
\end{align}

**Proof.** We first derive integrability conditions for (1.7) by introducing
\begin{equation}
Q_{BCA} = o^A \nabla_{\langle A} K_{BC \rangle}. \quad (3.28)
\end{equation}
For any geometry satisfying (3.1) we find
\begin{align*}
\Theta^{A'} Q_{BCA} = -4(\psi_3 K_0 - \psi_1 K_2) o_{\langle A} o_{B} o_{C \rangle} \\
+ 4(\psi_1 K_0 - 2\frac{1}{3} \psi_1 K_1) o_{\langle A} o_{B} o_{C \rangle} - 2\psi_1 K_{0} o_{\langle A} o_{B} o_{C \rangle}.
\end{align*}

The integrability conditions are then obtained by setting $Q_{BCA} = 0$, so the left-hand side of (3.29) vanishes. If $\psi_1 \neq 0$, it follows that $K_{AB} = 0$ is the only solution to (1.7), so we need to have at least $\psi_1 = 0$ to have non-trivial solutions. Since we are interested in type II, we can impose $\psi_1 = 0$. In that case (3.29) leads to the restrictions
\begin{align}
\psi_2 K_0 &= 0, \\
\psi_2 K_0 &= 0. \quad (3.30)
\end{align}
If $K_0 \neq 0$, the Weyl spinor would be of Petrov type N (i.e. only $\psi_4 \neq 0$). In that case (3.29) yields no restrictions on $K_{AB}$. For Petrov type D or II, we have $\psi_2 \neq 0$ which forces $K_0 = 0$. For $K_1$ and $K_2$, a compact form of the equations to be satisfied can be obtained in terms of the covariant derivative $\mathcal{C}_{\langle A'}$ and its projections $\tilde{\mathcal{C}}_{A'}, \mathcal{C}_{A'}$ given in (3.2). Using $K_0 = 0$, and requiring $K_{AB}$ to have conformal weight 2 so that the projected Killing spinor equation is conformally invariant, equation (1.7) is
\begin{equation}
0 = \tilde{\mathcal{C}}_{A'} K_{BC} + o_{B} \tilde{\mathcal{C}}_{A'C} K_1 + o_{C} \mathcal{C}_{A'B} K_1. \quad (3.31)
\end{equation}
Contraction with $o^B$ and with $i^B i^C$ leads to,
\begin{align}
\tilde{\mathcal{C}}_A K_1 &= 0, \quad (3.32) \\
\tilde{\mathcal{C}}_A K_2 + 2\mathcal{C}_A K_1 &= 0, \quad (3.33)
\end{align}
or in GHP notation
\begin{align}
(\bar{\tau} + \tau) K_1 &= 0, \\
(\bar{\rho} + \rho) K_1 &= 0, \\
2(\bar{\rho}' + \rho') K_1 + (\bar{\tau} + \tau') K_2 &= 0, \\
2(\bar{\rho}' + \rho') K_1 + (\bar{\rho} + 2\rho) K_2 &= 0. \quad (3.35)
\end{align}

**Remark 21 (Solution space of the projected Killing spinor equation).** In the real-analytic case, we see from equations (3.26) and (3.27) that the space of solutions to the projected Killing spinor equation is infinite dimensional. For example, one solution is given in (3.15), but we also see that, taking $K_1 \equiv 0$, equations (3.26) and (3.27) reduce to $\tilde{\mathcal{C}}_A K_2 = 0$. It follows from equations (3.9)–(3.11) that there is an infinite dimensional solution space to
this equation. Any function of the form \( F = \lambda^{-2} \phi^2 K_2 \), see remark \ref{remark:lambda_phi} and lemma \ref{lemma:lambda_phi} for the definition of \( \lambda \) and \( \phi \), which is constant on \( \beta \)-surfaces leads to a projected Killing spinor \( K_{AB} = \lambda^2 \phi^{-2} F_{aOB} \). We also mention that one could in principle consider \( K_1 \neq 0 \) and \( K_2 \equiv 0 \) (or \( \tilde{C}_A K_2 = 0 \), but then \eqref{eq:K1} and \eqref{eq:K2} leads to \( C_{AB} K_1 = 0 \), which, taking into account that the weights of \( K_1 \) are \( p = 0 \) and \( w = 1 \), is explicitly \( \nabla_a K_1 + f_a K_1 = 0 \). This implies \( f_a = -\nabla_a \log K_1 \) and so \( \nabla_{[a} f_{b]} = 0 \), which is a restriction on the geometry: this is satisfied for vacuum type D but not for arbitrary type II spacetimes.

### 3.2. Conservation laws

Finally, an interesting property of projected Killing spinors is that they give rise to solutions of the vacuum Maxwell equations, and therefore to conservation laws:

**Lemma 22.** Let \((\mathcal{M}, g_{ab})\) be real-analytic, and let \( \alpha^A \) be SFR and a repeated principal spinor. Let \( K_{AB} \) be a projected Killing spinor as in \eqref{eq:killing_spinor}. Assume \( K_1 = c \phi^{-1} \), where \( \phi \) was introduced in \eqref{eq:phi} and \( c \) is an arbitrary constant, possibly zero. Then the spinor field

\[
\varphi_{AB} = -2\phi^3 K_{AB}
\]  

\eqref{eq:phi}

is a solution to the vacuum Maxwell equations.

The result of this lemma is valid regardless of the Einstein condition, but it imposes the real-analyticity restriction, because we need the existence of the scalar field \( \phi \) introduced in lemma \ref{lemma:phi}. If the Einstein condition is assumed, then real-analyticity is not needed, see example \ref{example:einstein} below.

**Proof of lemma 22.** The proof is straightforward in terms of the conformal connection \eqref{eq:conformal_connection}. Since the field \eqref{eq:phi} has GHP weight \{0, 0\} and conformal weight \( w = -1 \), it follows from \eqref{eq:conformal_connection} that \( \nabla_A \phi \varphi_{AB} = C_A \phi \varphi_{AB} \). Replacing expression \eqref{eq:killing_spinor} for \( K_{AB} \) with \( K_0 = 0 \), and using \( C_{AA} \phi B = 0 \), we get

\[
\frac{1}{2} \nabla_A \varphi_{AB} = -\phi \tilde{C}_A (\phi^3 K_2) + \tilde{C}_A (\phi^3 K_1 t_B) - \phi \phi C_A (\phi^3 K_1 t_A)
\]

\[
= -\phi \phi \tilde{C}_A K_2 + \phi \phi C_A (\phi^3 K_1)
\]

\[
= 2 \phi \phi \tilde{C}_A K_1 + \phi \phi C_A (\phi^3 K_1)
\]

\[
= 3 \phi \phi \tilde{C}_A K_1 + \phi \phi C_A (\phi^3 K_1)
\]

\eqref{eq:phi}

where in the second line we used \( 0 = \tilde{C}_A \phi = \tilde{C}_A K_1 = \tilde{C}_A t_B \) and also \( C_A \phi t_A = 0 \) (which follows from \eqref{eq:centrifugal}), and in the third line we used equation \eqref{eq:phi}. Now, the scalar \( \phi \) has weights \{0, 0\} and \( w = 0 \), so from the definition \eqref{eq:conformal_connection} we have \( C_A (\phi K_1) = \phi^4 \nabla_A (\phi K_1) \). Therefore \( \nabla_A \phi \varphi_{AB} = 0 \) if and only if \( \phi^4 \nabla_A (\phi K_1) = 0 \). From lemma \ref{lemma:phi} it follows that this is true if and only if \( K_1 = c \phi^{-1} \) for some constant \( c \), which can be zero. \( \square \)

The result of lemma 22 tells us that, as long as \( K_1 = c \phi^{-1} \), we have the conservation law

\[
d\mathcal{F} = 0, \quad \mathcal{F}_{ab} = \varphi_{AB} \epsilon_{AB}.
\]  

\eqref{eq:conservation_law}
We note that, choosing $c = 0$, the Maxwell field (3.36) is $\varphi_{AB} = -2\phi^3 K_{OA OB}$, with $\mathcal{C}_s(\phi^3 K_2) = 0$. These are the Robinson null fields discussed for example in [22, theorem 7.3.14].

**Example 23 (Spin lowering).** If we assume that $(\mathcal{M}, g_{ab})$ is Einstein, then from (3.6) we know that $\phi = \psi_2^{1/3}$ and we do not need to restrict to real-analytic spacetimes. The Maxwell field (3.36) is $\varphi_{AB} = -2\psi_2 K_{AB}$. Choosing $c = 1$, it follows that

$$\varphi_{AB} = \psi_{ABCD} K^{CD}.$$ (3.39)

Thus, in this case, the result of lemma 22 can be interpreted as a form of Penrose’s spin lowering:

$$\nabla^{AA'} \varphi_{AB} = (\nabla^{AA'} \psi_{ABCD}) K^{CD} + \psi_{ABCD}(\nabla^{A'}(A K^{CD})) = 0,$$ (3.40)

where the first term on the right vanishes since $\nabla^{AA'} \psi_{ABCD} = 0$ are the Bianchi identities for an Einstein space, and the vanishing of the second term follows from the fact that the projected Killing spinor equation (1.7) implies $\nabla^{A'(A K^{CD})} = A^{A'} \sigma^A \sigma^B \sigma^C$ for some $A^{A'}$, and then one uses the type II condition (3.4).

**Example 24 (Sachs’ conservation law).** In [27, equation (5.23)], Sachs found a conservation law for vacuum type II spacetimes, where he chose a tetrad rotation such that $\psi_3 = 0$ to derive the conservation law

$$d \left( \frac{2\psi^2}{3} o(A'B')e_{AB'} \right) = 0.$$ (3.41)

From example 23 we see that this conservation law can be interpreted as a form of Penrose’s spin lowering without the necessity of imposing the tetrad gauge $\psi_3 = 0$, since the components of the Maxwell field (3.39) are

$$\varphi_0 = 0, \quad \varphi_1 = \psi_2^{2/3}, \quad \varphi_2 = \frac{2\psi_1}{3\psi_2^{1/3}},$$ (3.42)

which, using (3.38), shows the equivalence to the result of Sachs.

**4. Perturbation theory in terms of a Debye potential**

In this section we review first order perturbation theory of Einstein spacetimes of Petrov type II in terms of scalar potentials and prove theorem 3. We make use of the adjoint operator method introduced by Wald in [32] to generate solutions to the linearized Einstein equations from solutions of a scalar wave-like equation.

Introducing $h_{ab}$ as the linearized metric on an Einstein background with metric $g_{ab}$, the linearized Einstein equations are given by

$$-\frac{1}{2} \Box h_{ab} + 6\Lambda h_{ab} = -\frac{1}{2} \nabla_a \nabla_b (g^{cd} h_{cd}) + \nabla^c \nabla_{(a} h_{b)c}$$

$$-\frac{1}{2} g_{ab}(\nabla^c \nabla^d h_{cd} - \Box (g^{cd} h_{cd})) = 0,$$ (4.1)

$^{11}$ More precisely, $h_{ab}$ is the variational derivative w.r.t. $\lambda$ of the general metric $g_{ab} = g_{ab} + \lambda h_{ab} + O(\lambda^2)$ at $\lambda = 0$. 

with the wave operator defined by \( \Box = g^{ab} \nabla_a \nabla_b \). The linearized Einstein equations enter the argument below via the operator (4.4). The expression for the linearized ASD Weyl spinor \( \dot{\psi}_{ABCD} \) in terms of the linearized metric, as given by Penrose and Rindler in [21, equation (5.7.15)], is of the form

\[
\dot{\psi}_{ABCD} = \frac{1}{2} \nabla_A \nabla^A h_{CD} \nabla_B + \frac{1}{4} g^{ef} \dot{h}_{ef} \psi_{ABCD}. \tag{4.2}
\]

**Remark 25.** We note that the spinor variational operator \( \vartheta \) introduced in [7] leads to a minus sign of the trace term in (4.2). Since the linearized metrics generated from a scalar potential are trace-free, i.e. \( g^{ef} \dot{h}_{ef} = 0 \), see (4.15) for details, the result would be the same for \( \vartheta \psi_{ABCD} \).

However, since we are only interested in the ASD Weyl curvature here, there is no need to introduce the additional structures involving the \( \vartheta \) variation.

To state the underlying operator identity of Wald’s method, we begin with

**Definition 26.** Let \( x_{ab} \) be a (possibly complex) symmetric two-tensor, \( \Phi \) be a complex scalar field of GHP weight \( \{4,0\} \) and denote \( \nabla^a x_{ab} \) etc for tetrad components. Define the differential operators \( S, E, O, T \) by

\[
S(x_{ab}) := (\overline{\vartheta} - 4\tau - \vartheta') (\vartheta - 2\rho) x_{ab} - (\overline{\vartheta} - \vartheta') x_{ab} \\
+ (\vartheta - 4\rho - \rho') (\overline{\vartheta} x_{ab} + (\overline{\vartheta} - 2\vartheta') x_{ab} - (\vartheta - \rho) x_{ab}), \tag{4.3}
\]

\[
E(x)_{ab} := \left( -\frac{1}{2} \Box + 6\Lambda \right) x_{ab} - \frac{1}{2} \nabla_a \nabla_b (g^{cd} x_{cd}) + \nabla_a \nabla_b (g^{cd} x_{bd}) \\
- \frac{1}{2} g_{ab} (\nabla^c \nabla_c x_{cd} - \Box (g^{cd} x_{cd})), \tag{4.4}
\]

\[
O(\Phi) := 2(\vartheta - 4\rho - \rho') (\vartheta' - \rho') - (\overline{\vartheta} - 4\tau - \vartheta') (\overline{\vartheta} - \tau') - 3\psi_2 \Phi, \tag{4.5}
\]

\[
T(x_{ab}) := \frac{1}{2} (\overline{\vartheta} - 2\vartheta') \overline{\vartheta} - \overline{\vartheta}' (\vartheta - 2\rho) - 2(\vartheta' \vartheta') x_{ab} + \frac{1}{2} (\vartheta - 2\rho) \vartheta x_{ab} \\
- (\vartheta - 2\rho) (\overline{\vartheta} - \vartheta') (\vartheta - \rho) x_{ab}. \tag{4.6}
\]

**Remark 27.**

(a) Note that \( E \) defined in (4.4) is the linearized Einstein operator plus a cosmological term. This operator is formally self adjoint,

\[
E^\dagger = E. \tag{4.7}
\]

(b) Acting on a linearized metric \( h_{ab} \), the operator \( T \) defined in (4.6) yields the zero-component of the linearized anti-self dual Weyl curvature (4.2),

\[
T(h_{ab}) = \alpha^A \alpha^B \alpha^C \alpha^D \dot{\psi}_{ABCD} = \dot{\psi}_0. \tag{4.8}
\]

(c) For any \( h_{ab} \) such that \( E(h)_{ab} = 0 \), a decoupled wave-like (Teukolsky) equation is given by

\[
O T(h_{ab}) = O(\dot{\psi}_0) = 0. \tag{4.9}
\]

**Theorem 28 (Wald [32]).** On Einstein spacetimes of Petrov type II with repeated principal spinor \( \alpha^A \), the operators of definition 26 satisfy the identity

\[
S E = O T. \tag{4.10}
\]
Thus, in particular, if $\chi$ is a complex scalar field of GHP weight $\{-4, 0\}$ solving

$$O^\dagger \chi = 0,$$  \hfill (4.11)

then the complex metric $h_{ab} = S^\dagger(\chi)_{ab}$ solves the linearized Einstein equation

$$\mathcal{E}(h)_{ab} = \mathcal{E}(S^\dagger(\chi))_{ab} = 0.$$  \hfill (4.12)

In [32] the general idea was outlined and applied for Petrov type D, see [23] where the explicit form of $S$ is given on Petrov type II. The scalar field $\chi$ is called Debye potential and (4.11) is the Debye equation.

**Lemma 29.** Let $\chi$ be a complex scalar field of GHP weight $\{-4, 0\}$.

- The operators adjoint to $S$ and $O$ are given by
  
  $$S^\dagger(\chi)_{ab} = (l_1 m_0 (b - \rho + \bar{\rho}) - l_0 b (\bar{\delta} - \tau)) (\bar{\delta} + 3\tau) \chi$$
  
  $$+ (l_1 m_0 (\bar{\delta} - \tau + \bar{\rho}') - l_0 b \bar{\delta}' - m_0 m_0 (b - \rho)) (\bar{b} + 3\rho) \chi,$$  \hfill (4.13)

  $$O^\dagger \chi = 2 ((\bar{b}' - \bar{\rho}') (\bar{b} + 3\rho) - (\bar{\delta}' - \tau) (\bar{\delta} + 3\tau) - 3\psi_2) \chi.$$  \hfill (4.14)

- If $\chi$ solves the Debye equation (4.11), then the complex metric $h_{ab} = S^\dagger(\chi)_{ab}$ solving the linearized Einstein equation is given by
  
  $$h_{ab} = h_{nn} l_1 l_0 - 2 h_{nn} l_0 l_1 m_0 + h_{nn} m_0 m_0,$$  \hfill (4.15)

  with components

  $$h_{nn} = -(\bar{\delta} + 2\tau) \bar{\delta} \chi - \bar{\sigma}' p \chi,$$  \hfill (4.16)

  $$h_{nh} = -(b + \rho) \bar{\delta} \chi - (\tau + \bar{\tau}') p \chi,$$  \hfill (4.17)

  $$h_{nh} = -(b + 2\rho) p \chi.$$  \hfill (4.18)

**Proof.** The formal adjoints of the GHP operators are given by

$$\bar{b}^\dagger = -b + \rho + \bar{\rho}, \quad b'^\dagger = -b' + \rho + \bar{\rho}', \quad \bar{\delta}^\dagger = -\bar{\delta} + \tau + \bar{\tau}', \quad \bar{\sigma}' = -\bar{\sigma} + \tau + \bar{\tau},$$  \hfill (4.19)

see e.g. [1] for details. Using this, together with the rule $(AB)^\dagger = B'^\dagger A^\dagger$ for compositions, to compute the adjoint of (4.3) and (4.5) leads to (4.13).

The equation (4.16) are the simplified components of (4.13), using the commutator

$$[\bar{\delta}, \bar{b}] \chi = (\tau' b - \bar{\rho} \bar{\delta}) \chi,$$  \hfill (4.20)

and Ricci identities,

$$b \rho = \rho^2, \quad \bar{\delta} \tau = \tau^2 - \bar{\sigma}' \rho, \quad b \tau = \rho (\tau - \bar{\tau}'), \quad \bar{\sigma} \rho = \tau (\rho - \bar{\rho}),$$  \hfill (4.21)

valid on type II Einstein spacetimes with repeated principal spinor $\sigma^A$.

\[12\] It seems that there is a factor 4 missing in the operator identity in that reference.
Before proceeding to the proof of theorem 3, we need to introduce some additional identities and operators. First, similarly to definition 11, we introduce:

**Definition 30.** Let $(\sigma^A, \eta^A)$ be a spin dyad, $\Theta_{AA}$ the associated GHP connection, and $f_{AA'}$ the one-form (2.8). We define
\[
\hat{\Theta}^A := \sigma^A \Theta_{AA'}, \quad \Theta^A := \epsilon^A \Theta_{AA'}, \tag{4.22}
\]
\[
\hat{f}^A := \sigma^A f_{AA'}, \quad f^A := \epsilon^A f_{AA'}, \tag{4.23}
\]
\[
\sigma^A := \epsilon^A \nabla_{AA'B}. \tag{4.24}
\]

**Proposition 31.** If $\sigma^A$ is SFR, then
\[
\hat{\Theta}^A \sigma^B = 0, \quad \Theta^A \sigma^B = -\hat{f}^A \epsilon^B, \quad \hat{f}^A \epsilon^B = -\sigma^A \sigma^B, \quad \Theta^A \epsilon^B = \sigma^A \sigma^B. \tag{4.25}
\]

**Remark 32.** If $\sigma^A$ is SFR and a repeated principal spinor, using (3.5) we note that $\hat{f}^A$ can be written as
\[
\hat{f}^A = \hat{\Theta}^A \log \phi. \tag{4.26}
\]

Since in this section we are interested in the Einstein case, we can use (3.6) and replace $\phi = \psi_2^1 / \beta$.

**Proposition 33.** Let $(\mathcal{M}, g_{ab})$ be a type II Einstein spacetime with repeated principal spinor $\sigma^A$. On spinors of GHP weight $(p, 0)$ with an arbitrary number of primed indices the operators in (4.22) satisfy the following commutator relations,
\[
[\hat{\Theta}^A, \Theta^B] = 0, \tag{4.27}
\]
\[
[\hat{\Theta}^A, \Theta^B] = \epsilon_{A'B'} \frac{p}{2} (2 \hat{\Theta}^B f^{C'C} - \hat{f}^B f^{C'C} + 6 \Lambda) + \Box_A^{\Theta} - f_A^B \Theta^B + \hat{f}^B \Theta^B, \tag{4.28}
\]
\[
[\Theta^A, \Theta^B] = \epsilon_{A'B'} \left( p (\Theta^B f^{C'C} - \Theta^C f^{C'C}) - \sigma^A \sigma^B, (4.29)
\]
where $\Box_A^\Theta = \Theta_{AA'} \Theta^{A'}$.

**Proof.** We prove (4.27) explicitly, the other equations follow analogously. In a general spacetime, using definition (4.22) and acting on an arbitrary spinor $\varphi_{F...F}^{E...E}$ with GHP weight $(p, q)$ we get
\[
[\hat{\Theta}^A, \Theta^B] \varphi_{F...F_{E...E}}^{E...E} = \epsilon_{A'B'} \sigma^B \Theta^C f^{C'C} \Theta_{C}^{C'} \varphi_{F...F_{E...E}}^{E...E} + \sigma^A \sigma^B \Theta_{AB} \varphi_{F...F_{E...E}}^{E...E}. \tag{4.30}
\]
For the second term in the right, using GHP notation we find
\[
\sigma^A \sigma^B \Theta_{AB} \varphi_{F...F_{E...E}}^{E...E} = \sigma^A \sigma^B 
\]
\[
- \epsilon_{A'B'} \sigma^B \Theta_{AC} \Theta_{B}^{C'} \varphi_{F...F_{E...E}}^{E...E}
\]
\[
= - \epsilon_{A'B'} 
\]
\[
\sigma^B \Theta_{AC} \Theta_{B}^{C'} \varphi_{F...F_{E...E}}^{E...E}
\]
\[
+ \left( \rho (-\Psi_1 + \sigma \rho - \kappa \rho) + q (-\Phi_0 + \gamma' \rho - \kappa' \rho) \right) \varphi_{F...F_{E...E}}^{E...E}. \tag{4.31}
\]
where $\Box_{AB} = \nabla_A (\nabla_B)^{A'}$ is the usual spinor curvature operator [21, equation (4.9.2)]. Suppose now that the spacetime is Einstein and of Petrov type II. Restricting the identity (4.31) to primed spinor fields $\varphi_{\rho}^{\rho'}$, with GHP weight $\{p,0\}$, we get that each of the terms in the right-hand side vanishes: $\Box_{AB} \varphi_{\rho}^{\rho'} = 0$ because this only involves contractions with $\Phi_{AB\rho\rho'}$ which vanishes because of the Einstein condition; the term with $q$ vanishes because we are restricting to weight $\{p,0\}$; and the term with $p$ vanishes because the vacuum type II condition implies $\kappa = \sigma = \psi_1 = 0$. Furthermore, from this last condition we get $\Box_{AB} \nabla_{A} C_{B} = 0$ (see (3.1)), therefore (4.30) vanishes identically and we get the result (4.27).

**Remark 34.** Since $[\tilde{\Theta}_{A'}, \tilde{\Theta}_{B'}] = 2 \tilde{\Theta}_{[A'} \tilde{\Theta}_{B']} = -\tilde{\Theta}_{\tilde{C}'} \tilde{\Theta}_{C'}$, the result (4.27) can be equivalently stated as

$$\tilde{\Theta}_{A'} \tilde{\Theta}_{B'} \varphi_{\rho}^{\rho'} = 0 \quad (4.32)$$

for any primed spinor $\varphi_{\rho}^{\rho'}$ (or scalar) with weight $\{p,0\}$. This identity will be useful below.

**Proposition 35.** Let $\tilde{\Theta}_{A'}$ be as in (4.22), and let $\phi$ be given by (3.6). The linearized metric (4.15) can be expressed as

$$h_{\rho A' \rho B'} = o_{\rho A'} X_{\rho B'}, \quad (4.33)$$

where

$$X_{\rho B'} = -\tilde{\Theta}_{\tilde{A}'} \left( \phi^{2} \tilde{\Theta}_{\tilde{B}'} \chi \right). \quad (4.34)$$

The proof is given in appendix B.2.

**Proposition 36.** Let $(\mathcal{M}, g_{\mu \nu})$ be a type II Einstein spacetime with repeated principal spinor $\sigma^{A}$. The Ricci, Bianchi and commutator identities yield

$$\tilde{\Theta}_{A' \tilde{f}^{\rho} \rho} = \tilde{f}_{A' \tilde{f}^{\rho} \rho}, \quad (4.35)$$

$$\tilde{\Theta}_{A' \tilde{f}^{A}} = \Psi_2 + 2\Lambda, \quad (4.36)$$

$$\Theta_{A' \tilde{f}^{A}} = -\Psi_2 - 2\Lambda, \quad (4.37)$$

$$\tilde{\Theta}_{A' \Psi_2} = 3\tilde{f}_{A' \Psi_2}, \quad (4.38)$$

$$\tilde{\Theta}_{A' \tilde{\Theta}_{B'} \phi^{-1}} = 0, \quad (4.39)$$

with the scalar field $\phi$ defined in (3.6).

**Proof.** These equations can be checked by GHP expansion using for example [21, section 4.12].

The main result of this section is given in lemma 38 below, from which theorem 3 follows. The proof of lemma 38 involves long computations and we transfer some intermediate steps into the following:

**Proposition 37.** The Debye equation in this formulation is given by

$$\mathcal{O}^{\tilde{f}} \chi = 2\tilde{\Theta}_{A' \tilde{f}_{A'} \chi} + 3\tilde{f}_{A' \chi} - 6\Psi_2 \chi. \quad (4.40)$$

Repeated application of commutators on $\chi$ of weight $\{-4,0\}$ leads to
\begin{align}
\tilde{\Theta}_{\mathcal{A}} \Theta_{\mathcal{B}} \tilde{\Theta}^\mathcal{B} \chi &= - \tilde{f}^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \tilde{\Theta}_{\mathcal{A}} \chi + 3 \tilde{f}^{\mathcal{A}} \Lambda \tilde{\Theta}_{\mathcal{A}} \chi - \frac{15}{2} \tilde{f}^{\mathcal{A}} \psi_{\mathcal{A}} \tilde{\Theta}_{\mathcal{A}} \chi \\
&\quad - \frac{3}{2} \tilde{f}^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \tilde{\Theta}_{\mathcal{A}} \chi - 3 \tilde{f}^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \tilde{\Theta}_{\mathcal{A}} \chi + \frac{3}{2} \tilde{f}^{\mathcal{A}} \tilde{\Theta}_{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \tilde{\Theta}_{\mathcal{A}} \chi \\
&\quad - \frac{3}{2} \tilde{f}^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \tilde{\Theta}_{\mathcal{A}} \chi + \Theta_{\mathcal{A}} \chi + 3 f^{\mathcal{A}} \tilde{\Theta}_{\mathcal{A}} f^{\mathcal{B}} \tilde{\Theta}_{\mathcal{B}} \chi - \frac{3}{2} f^{\mathcal{A}} \tilde{\Theta}_{\mathcal{B}} f_{\mathcal{A}} \tilde{\Theta}_{\mathcal{B}} \chi.
\end{align}

(4.41)

\begin{align}
\tilde{\Theta}_{\mathcal{B}} \Theta_{\mathcal{A}} \tilde{\Theta}^\mathcal{A} \chi &= - \tilde{f}^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \tilde{\Theta}_{\mathcal{A}} \chi + 3 \tilde{f}^{\mathcal{A}} \Lambda \tilde{\Theta}_{\mathcal{A}} \chi - \frac{15}{2} \tilde{f}^{\mathcal{A}} \psi_{\mathcal{A}} \tilde{\Theta}_{\mathcal{A}} \chi \\
&\quad - \frac{3}{2} \tilde{f}^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \tilde{\Theta}_{\mathcal{A}} \chi - 3 \tilde{f}^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \tilde{\Theta}_{\mathcal{A}} \chi + \frac{3}{2} \tilde{f}^{\mathcal{A}} \tilde{\Theta}_{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \tilde{\Theta}_{\mathcal{A}} \chi \\
&\quad - \frac{3}{2} \tilde{f}^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \tilde{\Theta}_{\mathcal{A}} \chi + 3 f^{\mathcal{A}} \tilde{\Theta}_{\mathcal{A}} f_{\mathcal{B}} \tilde{\Theta}_{\mathcal{B}} \chi - \frac{3}{2} \tilde{f}^{\mathcal{A}} \tilde{\Theta}_{\mathcal{B}} f_{\mathcal{A}} \tilde{\Theta}_{\mathcal{B}} \chi.
\end{align}

(4.42)

\begin{align}
\Theta_{\mathcal{B}} \Theta_{\mathcal{A}} \tilde{\Theta}^\mathcal{B} \chi &= - 9 \chi f^{\mathcal{A}} f_{\mathcal{A}} \Lambda + 18 \chi \Lambda^2 - \frac{3}{4} f^{\mathcal{A}} f_{\mathcal{A}} O^1 \chi + \frac{9}{2} \Lambda O^1 \chi + \frac{1}{4} \Theta^1 \Theta^1 \chi \\
&\quad - 9 \chi f^{\mathcal{A}} f_{\mathcal{A}} \psi_2 - 36 \chi \Lambda \psi_2 + \frac{3}{2} O^1 \chi \psi_2 - 36 \chi \psi_2^2 + 3 \tilde{f}^{\mathcal{A}} \Lambda \Theta^1 \chi \\
&\quad - 30 \tilde{f}^{\mathcal{A}} \psi_2 \Theta^1 \chi + \frac{3}{2} \tilde{f}^{\mathcal{A}} \Theta^1 \chi \psi_2 - 18 \chi \tilde{f}^{\mathcal{A}} \Theta^1 \psi_2 - 3 \Lambda \Theta^1 \psi_2 \\
&\quad - 6 \psi_2 \Theta^1 \chi - \frac{3}{2} f^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta^1 \chi - \frac{9}{2} \tilde{f}^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{A}} \chi \\
&\quad - 3 f^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \Theta^1 \chi + \tilde{f}^{\mathcal{A}} \Theta_{\mathcal{A}} \Theta^1 \chi - \frac{3}{2} f^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \Theta^1 \chi \\
&\quad - 3 f^{\mathcal{A}} \Theta_{\mathcal{A}} \Theta_{\mathcal{B}} \Theta^1 \chi + 3 \tilde{f}^{\mathcal{A}} \Theta_{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \Theta^1 \chi - \Theta^1 \Lambda \Theta_{\mathcal{A}} \Theta_{\mathcal{B}} \chi \\
&\quad - 3 f^{\mathcal{A}} \Lambda \Theta_{\mathcal{A}} \Theta_{\mathcal{B}} \chi - \frac{3}{2} f^{\mathcal{A}} f_{\mathcal{A}} \Theta^1 \chi + 3 \Theta^1 \psi_2 \Theta^1 \chi \\
&\quad - \frac{3}{2} \tilde{f}^{\mathcal{A}} \Theta_{\mathcal{B}} f^{\mathcal{B}} \Theta^1 \chi - \frac{3}{2} \tilde{f}^{\mathcal{A}} \Theta^1 \chi f_{\mathcal{B}} \Theta^1 \chi - \frac{3}{2} f^{\mathcal{A}} f_{\mathcal{B}} \tilde{f}^{\mathcal{B}} \Theta^1 \chi \\
&\quad - \frac{3}{2} \tilde{f}^{\mathcal{A}} \Theta^1 \chi f_{\mathcal{B}} \Theta^1 \chi - \frac{3}{2} f^{\mathcal{A}} f_{\mathcal{B}} \tilde{f}^{\mathcal{B}} \Theta^1 \chi + 3 \Theta^1 \Theta^1 \Theta^1 \chi. \\
\end{align}

(4.43)

\begin{align}
\Theta_{\mathcal{B}} \Theta_{\mathcal{A}} \tilde{\Theta}^\mathcal{B} \chi &= - 6 \Lambda \Theta^1 \chi - 6 \psi_2 \Theta^1 \chi - \frac{1}{2} \Theta^1 \chi - 6 \chi \Theta_{\mathcal{A}} \psi_2 \\
&\quad + 3 \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{A}} \Theta^1 \chi + 3 \Theta_{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta^1 \chi - \frac{3}{2} \tilde{f}^{\mathcal{B}} \sigma^{\mathcal{B}} \Theta_{\mathcal{A}} \chi \\
&\quad - \frac{3}{2} \Theta_{\mathcal{B}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{B}} \Theta^1 \chi + \frac{3}{2} \Theta_{\mathcal{A}} \chi \Theta_{\mathcal{B}} \sigma^{\mathcal{B}} - \sigma^{\mathcal{B}} \Theta_{\mathcal{B}} \Theta_{\mathcal{A}} \chi.
\end{align}

(4.44)

\begin{align}
\Theta_{\mathcal{B}} \Theta_{\mathcal{A}} \Theta^1 \chi &= - 4 \chi f^{\mathcal{B}} \Lambda - 2 \chi f^{\mathcal{B}} \psi_2 + 4 \chi \tilde{f}^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \sigma^{\mathcal{A}} - 2 f^{\mathcal{B}} \tilde{f}^{\mathcal{A}} \Theta_{\mathcal{A}} \chi \\
&\quad - 2 f^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{A}} \chi - 6 \chi \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{A}} f^{\mathcal{A}} - 2 \chi \tilde{f}^{\mathcal{A}} \Theta_{\mathcal{A}} f^{\mathcal{B}} - 2 f^{\mathcal{A}} \tilde{f}^{\mathcal{B}} \Theta_{\mathcal{A}} \chi.
\end{align}
Lemma 38. The ASD curvature components of a metric of the form (4.15) and (4.16) are given by

\[
\psi_0 = 0 \quad (4.47)
\]

\[
\dot{\psi}_1 = 0 \quad (4.48)
\]

\[
\dot{\psi}_2 = 0 \quad (4.49)
\]

\[
\dot{\psi}_3 = -\frac{1}{4}(\tilde{\tau}\bar{\psi} - \rho\bar{\psi})\partial^i\chi, \quad (4.50)
\]

\[
\dot{\psi}_4 = -(\psi_2^4/3\chi)\Theta_\alpha + 3\psi_2^2 \Lambda \chi - \left(\frac{1}{8}\partial^i - \rho\partial^i + \tau\partial^i + 2\psi_2 + \frac{5}{2} \Lambda\right)\partial^i\chi. \quad (4.51)
\]

The proof is given in appendix B.3.

Proof of theorem 3. The result follows from lemma 38 by imposing the Debye equation (4.11). \qed

Remark 39. In the special case of vacuum Petrov type D and for tetrads invariant under \(\xi^a\), (4.51) reduces to \(\dot{\psi}_4 = \xi^a\nabla_a\chi\), see [1].

Remark 40. Let us finally compare to three references closely related to the results of this section.

(a) In [17] Kegeles and Cohen discuss Debye potentials for algebraically special geometries. They restricted to vacuum Petrov type D for the derivation of the linearized Weyl spinor, see equation (5.28) in that reference. They reduced the ASD Weyl curvature to type N and also \(\dot{\psi}_4\) to first order.

(b) In [29], Stewart derived the linearized connection and curvature components for vacuum type II perturbations in terms of a Debye potential. However, the result was not fully simplified, see equation (4.35) of that reference, so that the type N property could not be observed. The result was also presented in terms of a real metric, which means that all terms involving \(\tilde{\chi}\) correspond to self dual Weyl curvature, while \(\chi\) terms belong to anti-self dual Weyl curvature.
It should also be noted that in general, linearized dyad components differ from dyad components of the linearized field. In this paper \( \dot{\psi} \) refers to the latter, while Stewart used the linearized Newman–Penrose equations, i.e. the former. However, he made a special choice of linearized tetrad for which the two sets of linearized Weyl components coincide.

(c) In [16], Jeffries discusses a reduction to scalar potentials for algebraically special solutions to the full non-linear Einstein–Yang–Mills equations. Further it is shown that, to linear order, this construction reduces to the Debye potential formulation. Remarkably, the ASD Weyl curvature can be simplified already on the non-linear level, so that theorem 3 we discuss here follows from the linearized equations (8.75-77) of that reference.

5. Summary and conclusions

In this paper, we have analyzed the properties of Petrov type II geometries. The more special case of vacuum Petrov type D is closely linked to the existence of the Killing spinor (1.1). Due to integrability conditions of the Killing spinor equation (1.2), it generically does not have solutions in the type II case. However, we show in proposition 16 that the more general object (3.15) exists, solving the projected Killing spinor equation (1.7). This equation is a weaker condition than the original Killing spinor equation due to the projection, as can also be seen in the tensorial form (1.13). We note that (3.15) exists without restrictions on the Ricci tensor. Restricting to the Einstein case, this object can be expressed in the more explicit form (1.5) and its derivative solves the projected Killing vector equation (1.8). It should be noted that for any vacuum type II geometry, one can explicitly compute (1.5) and then \( \zeta_a \) defined by (1.6) solves the projected Killing vector equation. This does not imply that any solution to (1.8) is of this form.

We then show in lemma 22 that a conservation law is linked to the projected Killing spinor. The result reduces in the vacuum case to a conservation law due to Sachs, as shown in example 24.

Finally, in section 4 we consider first order perturbation theory of type II Einstein spaces in terms of Debye potentials. Here the main result, given in lemma 38, is that the anti-self dual linearized Weyl spinor is of Petrov type N and that the remaining component reduces to a first order operator on the potential—this was previously known in the literature for the type D case. Curiously, the just mentioned first order operator is tightly related to the projected Killing vector \( \xi^a \) discussed in previous sections.

This work raises several questions that deserve to be analyzed in more detail in the future. The projected Killing spinors and vectors introduced in this paper will potentially be very useful in the analysis of type II solutions as well as for field equations on such geometries (e.g. in terms of symmetry operators). It would also be interesting to find a physical interpretation to the conservation law found in lemma 22. Finally, it is also worth investigating the Petrov type N property of the anti-self dual linearized Weyl spinor in relation to conjecture 1.

Data availability statement

No new data were created or analysed in this study.

Appendix A. Robinson–Trautman metrics

In 1968, Robinson and Trautman [25], published a line element for which the vacuum Einstein equations reduce essentially to a non-linear fourth order equation for a real scalar function. It admits solutions of all Petrov types. Here we briefly review the reduction and also the explicit example of Petrov type II given in [25].

In coordinates \((u, r, \zeta, \bar{\zeta})\) and with real functions \(H, P\), define the tetrad
\[
l^a = (\partial_r)^a, \quad n^a = (\partial_u)^a - H(\partial_r)^a, \quad m^a = Pr^{-1}(\partial_\zeta)^a, \quad \bar{m}^a = Pr^{-1}(\partial_{\bar{\zeta}})^a.
\]  

Due to the normalization \(l^a n_a = 1, m^a \bar{m}_a = -1\), the inverse is given by
\[
l_a = du, \quad n_a = dr + H du, \quad m_a = -rP^{-1} d\zeta, \quad \bar{m}_a = -rP^{-1} d\bar{\zeta},
\]  

so that the metric \(g_{ab} = 2l^a n_b - 2m^a \bar{m}_b\) is of the form
\[
g_{ab} = 2 dr du + 2H dr du - 2r^2 P^{-2} d\zeta d\bar{\zeta}.
\]  

This metric is Ricci flat if \(H\) is given by
\[
H = P^2 \partial_\zeta \partial_{\bar{\zeta}} \log(P) - r \partial_u \log(P) - mr^{-1}, \quad \text{with } m = m(u),
\]  

and \(P\) being independent of \(r\), solving
\[
P^2 \partial_\zeta \partial_{\bar{\zeta}} \left(P^2 \partial_\zeta \partial_{\bar{\zeta}} \log(P)\right) - \partial_u m + 3m \partial_u \log(P) = 0.
\]  

For the connection and curvature we find
\[
\kappa = \sigma = \alpha' = \tau = \tau' = \epsilon = 0, \quad R_{ab} = 0, \quad \psi_0 = \psi_1 = 0,
\]  

in particular the metric is algebraically special. The non-vanishing spin coefficients are given by
\[
\kappa' = -Pr^{-1} \partial_{\bar{\zeta}} H, \quad \rho = -r^{-1}, \quad \rho' = Hr^{-1} \partial_u \log(P),
\]  

\[
\gamma = \frac{1}{2} \partial_\zeta H, \quad \alpha = \frac{1}{2} r^{-1} \partial_{\bar{\zeta}} P, \quad \beta = -\frac{1}{2} r^{-1} \partial_u P,
\]  

with \(H\) given in (A.4) and the remaining Weyl components are of the form
\[
\psi_2 = -mr^{-3}, \quad \psi_3 = -Pr^{-2} \partial_{\bar{\zeta}} \left(P^2 \partial_\zeta \partial_{\bar{\zeta}} \log(P)\right),
\]  

\[
\psi_4 = r^{-2} \partial_{\bar{\zeta}} \left(P^2 \partial_\zeta \partial_{\bar{\zeta}} \log(P) - r \partial_u \log(P)\right).
\]  

An explicit example of a type II geometry, found in [25], is given by
\[
P = (\zeta + \bar{\zeta})^{1/2}, \quad m = \text{const.}
\]
leading to $H = -m/r - 3(\zeta + \bar{\zeta})/2$ and to the metric
\begin{equation}
g_{ab} = 2 \, dr du - \left( 3(\zeta + \bar{\zeta}) + 2m/r \right) \, du \, du - 2r^2(\zeta + \bar{\zeta})^{-3} \, d\zeta d\bar{\zeta}, \tag{A.10}
\end{equation}
see also [28, section 28]. The spin coefficients reduce to
\begin{align}
\kappa' &= \frac{3(\zeta + \bar{\zeta})}{2r}, \quad \rho = \frac{1}{r}, \quad \rho' = \frac{3(\zeta + \bar{\zeta})}{2r}, \tag{A.11} \\
\gamma &= \frac{m}{2r^2}, \quad \alpha = -\beta = \frac{3(\zeta + \bar{\zeta})^{3/2}}{4r},
\end{align}
and the curvature components are given by
\begin{align}
\psi_2 &= -\frac{m}{r^2}, \quad \psi_3 = \frac{3(\zeta + \bar{\zeta})^{3/2}}{2r^2}, \quad \psi_4 = -\frac{9(\zeta + \bar{\zeta})^2}{2r^2}. \tag{A.12}
\end{align}

### Appendix B. Proofs

#### B.1. Proof of proposition 16

**Proof.** Equation (3.14) follows simply from (2.9)–(2.10), so we see that analyticity is not required for this item. For the second item, applying the definition (2.5) to the field $o_B|_C$, whose weights are $\{0, 0\}$ and $w = 1$, we have
\begin{equation}
C_{A|A}(o_B|_C) = \nabla_{A|A}(o_B|_C) + f_{A|A}o_B|_C - f_{A|B}o_A|_C - f_{A|C}o_B|_A. \tag{B.1}
\end{equation}
But from (2.9)–(2.10) we see that
\begin{equation}
C_{A|A}(o_B|_C) = \sigma_{A|A}o_B|_C, \tag{B.2}
\end{equation}
thus $C_{A|A}(o_B|_C) = C_{A|A}(o_B|_C)$. Combining with (B.1), we get
\begin{equation}
C_{A|A}(o_B|_C) = C_{A|A}(o_B|_C) = (\nabla_{A|A} - f_{A|A})o_B|_C. \tag{B.3}
\end{equation}
Using (3.5), this is
\begin{align}
C_{A|A}(o_B|_C) &= \phi \nabla_{A|A}[\phi^{-1}o_B|_C] + o_{A|A}o_B|_C \tilde{C}_{A|\eta} \\
&= \phi \left[ \nabla_{A|A}[\phi^{-1}o_B|_C] + t_{A|A} \tilde{C}_{|A}[\phi^{-1}o_B|_C] \right],
\end{align}
where in the second line we used that $\tilde{C}_{A|\eta}o_B|_C = 0, \tilde{C}_{A|\eta} \phi = 0$. Contracting this equation with $\sigma^A$ and using (B.2) gives
\begin{equation}
0 = \sigma^A \nabla_{A|A}[\phi^{-1}o_B|_C] + o^A t_{A|A} \tilde{C}_{|A}[\phi^{-1}o_B|_C]. \tag{B.4}
\end{equation}
Let us compute the second term in the right-hand side. Using $\sigma^A \tilde{C}_{A|\eta} = \tilde{C}_{A}(\sigma^A \cdot)$, we get
\begin{align}
\sigma^A t_{A|A} \tilde{C}_{|A}[\phi^{-1}o_B|_C] &= -\frac{1}{3} \tilde{C}_{A}[\phi^{-1}o_B|_C] = -\sigma^A C_{A|A}[\phi^{-1}o_B|_C].
\end{align}
Noticing that the weights of the field $\phi^{-1}o_B|_C$ are $\{0, 0\}$ and $w = 2$, and using the definition (2.5), we have
\begin{equation}
C_{A|A}[\phi^{-1}o_B|_C] = \nabla_{A|A}[\phi^{-1}o_B|_C]. \tag{B.5}
\end{equation}
Therefore
\[ o^A_{\mu\nu} \tilde{C}_{\nu\mu}((\phi^{-1} \eta_oB o C)) = -o^A \nabla_A(\phi^{-1} \eta_oB o C) \]
and thus
\[ 0 = o^A \nabla_A \left[ \phi^{-1} \eta_oB o C - \phi^{-1} \eta_oB o C \right], \tag{B.6} \]
hence the result follows. \(\square\)

### B.2. Proof of proposition 35

**Proof.** This can be shown by direct comparison with (4.15) and (4.16). First, from (4.33) we see that the only non-trivial components are
\[ X_{11} = c^\nu c^\mu \eta_oC h_{\mu\nu} = \eta_{mn}, \tag{B.7a} \]
\[ X_{01} = c^\nu c^\mu \eta_oB h_{\mu\nu} = \eta_{mn}, \tag{B.7b} \]
\[ X_{00} = c^\nu c^\mu \eta_oB h_{\mu\nu} = \eta_{mn}, \tag{B.7c} \]
so the general structure (4.15) is recovered. Now we check that these components coincide with (4.16). To do this, we write
\[ X_{A'B'} = -\Theta_{A'} \tilde{\Theta}_{B'} \chi - 2(\Theta_{A'} \log \phi)(\tilde{\Theta}_{B'} \chi). \tag{B.8} \]
Next, we project this expression over the primed spin dyad (\(\bar{\eta}_A, \bar{\eta}_B\)) to compute the components (B.7a). We will need the following identities:
\[ \bar{\rho} \log \phi = \rho, \quad \bar{\delta} \log \phi = \tau, \tag{B.9} \]
which follow from the fact that \(\phi = \psi^{1/3}\) (equation (3.6)) together with the Bianchi identities for a Petrov type II spacetime. Then we have, for example,
\[ X_{11} = -c^\nu c^\mu \Theta_{A'} \tilde{\Theta}_{B'} \chi - 2\bar{\delta} \log \phi \delta \chi \]
\[ = -\delta \delta \chi + (\delta \delta \chi - 2\delta \delta \chi) \]
\[ = - (\delta + 2\tau) \delta \chi - \delta ' \delta \chi, \tag{B.10} \]
where we used \(\delta \delta \chi = -\delta ' \delta \chi\), see [21, equation (4.12.28)]. The other components can be computed along the same line. \(\square\)

### B.3. Proof of lemma 38

**Proof.** The result is verified by direct computation using the projected operators \(\Theta_A, \tilde{\Theta}_A\) defined in (4.22) and their commutator properties (4.27). The first step is to derive an appropriate form for the components of the linearized ASD Weyl curvature spinor (4.2). Replacing (4.33) in (4.2) and using (4.22), (4.23) and (4.25), we find
\[ \dot{\psi}_0 = 0, \tag{B.11a} \]
\[ \dot{\psi}_1 = 0, \tag{B.11b} \]
\[ \dot{\psi}_2 = \frac{1}{12} (\tilde{\Theta}_B + 2 \tilde{f}_B)(\tilde{\Theta}_A + 2 \tilde{f}_A) X^\alpha \chi, \] (B.11c) 

\[ \dot{\psi}_3 = \frac{1}{8} \left( (\tilde{\Theta}_B + f_B)(\tilde{\Theta}_A + 2 \tilde{f}_A) + (\tilde{\Theta}_B + 3 \tilde{f}_B) \Theta_B \right) X^\alpha \chi, \] (B.11d) 

\[ \dot{\psi}_4 = \frac{1}{2} \left( \Theta_B \Theta_A - \sigma_A (\tilde{\Theta}_A + 2 \tilde{f}_A) \right) X^\alpha \chi. \] (B.11e)

So the first two equations, (B.11a) and (B.11b), follow from the algebraic structure of (4.34). For \( \dot{\psi}_2 \), rewrite the operator in (B.11c) using (4.26) and insert (4.34),

\[ \dot{\psi}_2 = \frac{1}{12} \phi^{-2} \tilde{\Theta}_B \tilde{\Theta}_A (\phi^2 X^\alpha \chi) = \frac{1}{12} \phi^{-2} \tilde{\Theta}_B \tilde{\Theta}_A \tilde{\Theta} \chi, \] (B.12)

where the last step follows from (4.32). Next we compute \( \dot{\psi}_3 \) by first inserting (4.34) into (B.11d) and expanding out,

\[ \dot{\psi}_3 = - \frac{1}{8} f_A^{\alpha} \tilde{\Theta}_B \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi - \frac{1}{16} \tilde{\Theta}_A \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi + \frac{5}{8} f_A^{\alpha} \tilde{f}_B \Theta_B \tilde{\Theta}^\alpha \chi + \frac{5}{16} \tilde{f}_B \Theta_B \tilde{\Theta}^\alpha \chi + \frac{5}{8} \tilde{f}_B \tilde{\Theta}^\alpha \chi - \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi - \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi + \frac{5}{8} \tilde{f}_B \tilde{\Theta}^\alpha \chi - \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi - \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi - \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi - \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi + \frac{3}{4} \tilde{f}_A^{\alpha} \tilde{f}_B \tilde{\Theta}^\alpha \chi + \frac{3}{4} \tilde{f}_B \tilde{\Theta}^\alpha \chi - \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi - \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi - \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi - \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi + \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi + \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi + \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi + \frac{1}{8} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi. \] (B.13)

Using (4.35) and (4.27) yields

\[ \dot{\psi}_3 = \frac{7}{8} f_A^{\alpha} \tilde{f}_B \Theta_B \tilde{\Theta}^\alpha \chi + \frac{1}{2} f_A^{\alpha} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi + \frac{3}{2} f_A^{\alpha} \tilde{\Theta}^\alpha \chi \]

\[ + \frac{9}{8} f_A^{\alpha} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi - \frac{1}{8} f_A^{\alpha} \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi - \frac{1}{16} \tilde{\Theta}_A \tilde{\Theta}_B \tilde{\Theta}^\alpha \chi + \frac{3}{8} f_A^{\alpha} \tilde{f}_B \tilde{\Theta}^\alpha \chi - \frac{3}{8} f_A^{\alpha} \tilde{f}_B \tilde{\Theta}^\alpha \chi - \frac{3}{8} f_A^{\alpha} \tilde{f}_B \tilde{\Theta}^\alpha \chi - \frac{3}{8} f_A^{\alpha} \tilde{f}_B \tilde{\Theta}^\alpha \chi - \frac{3}{8} f_A^{\alpha} \tilde{f}_B \tilde{\Theta}^\alpha \chi - \frac{3}{8} f_A^{\alpha} \tilde{f}_B \tilde{\Theta}^\alpha \chi - \frac{3}{8} f_A^{\alpha} \tilde{f}_B \tilde{\Theta}^\alpha \chi - \frac{3}{8} f_A^{\alpha} \tilde{f}_B \tilde{\Theta}^\alpha \chi. \] (B.14)
To eliminate 4th order terms, we use (4.41) and (4.42), leading to

\[
\tilde{\psi}_3 = \tilde{f}^{\alpha'} \tilde{f}^{\beta'} \Theta_{\beta' \alpha'} \chi + \frac{1}{2} \tilde{f}^{\alpha'} \Theta_{\alpha'} \tilde{f}^{\beta'} \tilde{\Theta}_{\beta' \alpha'} \chi + \frac{9}{8} \tilde{f}^{\alpha'} \Lambda \tilde{\Theta}_{\alpha'} \chi
\]
\[
+ \frac{33}{16} \tilde{f}^{\alpha'} \psi_2 \tilde{\Theta}_{\alpha'} \chi - \frac{1}{8} \tilde{f}^{\alpha'} \tilde{\Theta}_{\alpha'} \psi_2 \tilde{\Theta}_{\alpha'} \chi + \frac{3}{16} f^{\alpha'} \tilde{f}^{\beta'} \tilde{\Theta}_{\alpha'} \tilde{\Theta}_{\beta'} \chi
\]
\[
+ \frac{3}{8} \tilde{f}^{\alpha'} \Theta_{\beta' \alpha'} \tilde{f}^{\beta'} \tilde{\Theta}_{\beta' \alpha'} \chi - \frac{3}{8} \tilde{f}^{\alpha'} \Theta_{\beta' \alpha'} \tilde{f}^{\beta'} \tilde{\Theta}_{\beta' \alpha'} \chi - \frac{1}{8} \tilde{f}^{\alpha'} \chi \tilde{\Theta}_{\beta' \alpha'} \tilde{f}^{\beta'}
\]
\[
- \frac{1}{8} \tilde{f}^{\alpha'} \Theta_{\beta' \alpha'} \tilde{\Theta}_{\beta' \alpha'} \chi - \frac{1}{8} \tilde{f}^{\alpha'} \Theta_{\beta' \alpha'} \tilde{f}^{\beta'} \tilde{\Theta}_{\alpha'} \chi + \frac{1}{16} f^{\alpha'} \tilde{f}^{\beta'} \tilde{\Theta}_{\alpha'} \tilde{\Theta}_{\beta'} \chi
\]
\[
- \frac{3}{16} \tilde{f}^{\alpha'} \tilde{\Theta}_{\alpha' \beta'} \tilde{f}^\beta \tilde{\Theta}_{\beta' \alpha'} \chi + \frac{3}{16} \tilde{f}^{\alpha'} \tilde{\Theta}_{\alpha' \beta'} f^\beta \tilde{f}^\beta \chi. \quad (B.15)
\]

Using the commutators (4.27), (4.28) and the Debye equation (4.40) together with (4.35) takes care of third order terms,

\[
\tilde{\psi}_3 = - \frac{13}{8} \tilde{f}^{\alpha'} \Lambda \tilde{\Theta}_{\alpha'} \chi - \frac{13}{16} \tilde{f}^{\alpha'} \psi_2 \tilde{\Theta}_{\alpha'} \chi - \frac{1}{4} \tilde{f}^{\alpha'} \tilde{\Theta}_{\alpha'} \psi_2 \chi
\]
\[
+ \frac{3}{8} \tilde{f}^{\alpha'} \Theta_{\beta' \alpha'} \tilde{f}^{\beta'} \tilde{\Theta}_{\beta' \alpha'} \chi - \frac{3}{8} \tilde{f}^{\alpha'} \Theta_{\beta' \alpha'} \tilde{f}^{\beta'} \tilde{\Theta}_{\beta' \alpha'} \chi
\]
\[
+ \frac{7}{16} \tilde{f}^{\alpha'} \Theta_{\beta' \alpha'} f^\beta \tilde{\Theta}_{\beta' \alpha'} \chi - \frac{7}{16} \tilde{f}^{\alpha'} \tilde{\Theta}_{\alpha' \beta'} f^\beta \tilde{\Theta}_{\beta' \alpha'} \chi. \quad (B.16)
\]

Finally, the irreducible decompositions

\[
\tilde{\Theta}_{\alpha' \beta'} = \tilde{\Theta}_{\alpha' \beta'} + \frac{1}{2} \epsilon_{\alpha' \beta'} \tilde{\Theta} \tilde{f}^\gamma, \quad (B.17a)
\]
\[
\Theta_{\alpha' \beta'} = \Theta_{\alpha' \beta'} + \frac{1}{2} \epsilon_{\alpha' \beta'} \Theta \tilde{f}^\gamma. \quad (B.17b)
\]

lead to

\[
\tilde{\psi}_3 = - \frac{1}{4} \tilde{f}^{\alpha'} \tilde{\Theta}_{\alpha'} \psi_2 \chi, \quad (B.18)
\]

which gives (4.50) by GHP expanding \( \tilde{f}^{\alpha'} \tilde{\Theta}_{\alpha'} \).

To compute \( \tilde{\psi}_4 \), insert (4.34) into (B.11e) and use the identity (4.43) together with the Debye equations (4.40) and (4.35) leading to

\[
\tilde{\psi}_4 = \frac{9}{2} \chi f^{\alpha'} \tilde{f}_{\alpha'} \Lambda = - 18 \chi \Lambda^2 + \frac{3}{8} f^{\alpha'} f_{\alpha'} (O^j)^{\alpha'} \chi - 2 \Lambda (O^j)^{\alpha'} \chi - \frac{1}{8} (O^j)^{\alpha'} \chi + \frac{9}{2} \chi f^{\alpha'} f_{\alpha'} \psi_2
\]
\[
+ 6 \chi \Lambda \psi_2 - \frac{7}{4} (O^j)^{\alpha'} \psi_2 + \frac{15}{2} \chi \psi_2^2 + \frac{21}{2} \chi \tilde{f}^{\alpha'} \psi_2 \Theta_{\alpha'} \chi + 6 \chi \Lambda \Theta_{\alpha'} f^{\alpha'} - \frac{3}{2} \chi \psi_2 \theta_{\alpha'} f^{\alpha'}
\]
\[
- \frac{1}{2} \tilde{f}^{\alpha'} \Theta_{\alpha'} \psi_2 + \frac{21}{2} \chi \tilde{f}^{\alpha'} \Theta_{\alpha'} \psi_2 + \frac{3}{2} \chi \tilde{f}^{\alpha'} \Theta_{\alpha'} \Theta_{\beta'} f^{\beta'} + \frac{3}{4} f^{\alpha'} \tilde{f}^{\beta'} \Theta_{\alpha'} \tilde{\Theta}_{\beta'} \chi
\]
\[
+ \frac{9}{4} f^{\alpha'} \tilde{f}_{\alpha'} \tilde{f}^{\beta'} \Theta_{\beta'} \chi + \frac{3}{2} \tilde{f}^{\alpha'} \Theta_{\alpha'} \Theta_{\beta'} \tilde{f}^{\beta'} + 3 \tilde{f}^{\alpha'} \tilde{f}^{\beta'} \Theta_{\alpha'} \tilde{\Theta}_{\beta'} \chi
\]
\[
- \frac{1}{2} \tilde{f}^{\alpha'} \Theta_{\alpha'} \tilde{f}^{\beta'} \tilde{\Theta}_{\beta'} \chi + \frac{3}{4} f^{\alpha'} \tilde{f}^{\beta'} \Theta_{\beta'} \tilde{\Theta}_{\beta'} \chi.
\]
\[ + \frac{3}{2} \hat{f}^{\alpha'} \Theta_{\alpha'} \Theta^\beta \Theta_{\alpha' \beta'} - \frac{3}{2} \hat{f}^{\alpha'} \Theta_{\alpha'} \hat{f} \Theta_{\beta'} + \Theta_{\alpha'} \hat{f} \Theta_{\beta'} \hat{f}^{\alpha'} \]
\[ + \frac{1}{2} \Theta_{\beta'} \hat{\Theta}_{\alpha'} \Theta_{\alpha' \beta'} + \frac{3}{2} \hat{f}^{\alpha'} \Lambda \hat{\Theta}_{\alpha' \beta'} + \frac{3}{4} \hat{f}^{\alpha'} \psi_2 \hat{\Theta}_{\alpha' \beta'} - \Theta_{\alpha'} \psi_2 \hat{\Theta}_{\alpha' \beta'} \]
\[ + \frac{3}{4} \hat{f}^{\alpha'} \Theta_{\alpha'} f^{\beta'} \hat{\Theta}_{\alpha' \beta'} + \frac{3}{4} \hat{f}^{\alpha'} \Theta_{\alpha'} f^{\beta'} \hat{\Theta}_{\alpha' \beta'} \]
\[ + \frac{3}{4} \hat{f}^{\alpha'} \Theta_{\alpha'} \hat{f}^{\beta'} \hat{\Theta}_{\alpha' \beta'} + \frac{1}{2} \Theta_{\alpha'} \Theta_{\beta'} \hat{f} \Theta_{\alpha' \beta'} - \frac{3}{4} \hat{f}^{\alpha'} \Theta_{\alpha'} f_{\alpha'} \hat{\Theta}_{\beta'} \]
\[ + \frac{3}{2} \hat{f}^{\alpha'} \Theta_{\alpha'} \hat{f}^{\beta'} \hat{\Theta}_{\alpha' \beta'} + \frac{1}{2} \hat{f}^{\alpha'} \Theta_{\alpha'} \hat{f} \hat{\Theta}_{\alpha' \beta'} - \frac{1}{4} \hat{f}^{\alpha'} \hat{f}^{\beta'} \sigma_{\alpha'} \hat{\Theta}_{\alpha' \beta'} \]
\[ - \frac{1}{4} \sigma_{\alpha'} \hat{\Theta}_{\alpha'} \Theta_{\beta'} \Theta_{\alpha' \beta'}. \quad (B.19) \]

To convert third order terms we use identities (4.44)–(4.46). After a commutator (4.28) and (4.35) is used, we have
\[ \hat{\psi}_4 = \frac{9}{4} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \Lambda + 6 \chi \Lambda^2 + \frac{3}{8} \hat{f}^{\alpha'} \hat{f}_{\alpha'} O^1 \chi - 2 \Lambda O^1 \chi - \frac{1}{8} O^1 O^1 \chi + \frac{9}{2} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \psi_2 \]
\[ + 9 \chi \Lambda \psi_2 - \frac{2}{4} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \Theta_{\alpha' \beta'} \chi - \frac{3}{4} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \Theta_{\alpha' \beta'} \chi - \frac{3}{2} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \Theta_{\alpha' \beta'} \chi - \frac{1}{2} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \Theta_{\alpha' \beta'} \chi \]
\[ + \frac{1}{2} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \Theta_{\alpha' \beta'} \chi - \frac{3}{2} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \Theta_{\alpha' \beta'} \chi - \frac{3}{4} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \Theta_{\alpha' \beta'} \chi - \frac{1}{4} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \Theta_{\alpha' \beta'} \chi. \quad (B.20) \]

Now, the commutator (4.27) together with the irreducible decomposition
\[ \Theta_{\alpha'} \hat{\Theta}_{\beta'} \chi = \Theta_{\alpha'} \hat{\Theta}_{\beta'} \chi + \frac{1}{2} \epsilon_{\alpha' \beta'} \Theta_{\gamma} \hat{\Theta}_{\gamma} \chi, \quad (B.21) \]

and (4.40) and (4.35) yields
\[ \hat{\psi}_4 = - \frac{5}{2} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \chi \]
\[ - \frac{5}{2} \hat{f}^{\alpha'} \Theta_{\alpha' \beta'} \chi + \frac{3}{4} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \Theta_{\alpha' \beta'} \chi \]
\[ - \frac{5}{4} \hat{f}^{\alpha'} \Theta_{\alpha'} \hat{f}_{\alpha'} \Theta_{\alpha' \beta'} \chi \]
\[ - \frac{3}{4} \hat{f}^{\alpha'} \Theta_{\alpha'} \hat{f}_{\alpha'} \Theta_{\alpha' \beta'} \chi \]
\[ + \frac{1}{2} \hat{f}^{\alpha'} \hat{f}_{\alpha'} \chi \Theta_{\beta'} \sigma_{\beta'} \chi. \quad (B.22) \]
The Ricci identity
\[ 2\psi_3 - \tilde{f}_{\sigma^{\prime}} \sigma^{\prime}\theta + \Theta_{\sigma^{\prime}} f_{\sigma^{\prime}} - \tilde{\Theta}_{\sigma^{\prime}} \sigma^{\prime} = 0. \] (B.23)
and the irreducible decompositions (B.17b) and
\[ \Theta_{\alpha'} f_{\beta'} = \Theta_{\alpha'} f_{\beta'} + \frac{1}{2} \epsilon_{\alpha' \beta'} \epsilon_{\sigma' \tau'} f_{\tau'}. \] (B.24)
lead to
\[ \dot{\psi}_4 = -\frac{5}{2} \Lambda \tilde{O}^1 \chi - \frac{1}{8} \tilde{O}^1 \tilde{O}^1 \chi - 6 \chi \Lambda \psi_2 - 2 \tilde{O}^1 \chi \psi_2 - 3 \chi \psi_2^2 - 3 \frac{\tilde{f}^{\sigma'} \sigma' \psi_2 \Theta_{\sigma'} \chi}{2} \] (B.25)
To bring it into the final form we use the Bianchi identity
\[ -3f_{\alpha'} \psi_2 + 2 \tilde{f}_{\alpha'} \psi_3 + \Theta_{\alpha'} \psi_2 - \tilde{\Theta}_{\alpha'} \psi_3 = 0, \] (B.26)
resulting in
\[ \dot{\psi}_4 = -\frac{3}{2} \psi_2 (f_{\sigma'} \tilde{\Theta}_{\sigma'} + \tilde{f}_{\sigma'} \Theta_{\sigma'} + 2 \psi_2 + 4 \Lambda) \chi + \frac{1}{2} (\tilde{\Theta}_{\alpha'} - 4 \tilde{f}_{\alpha'} ) \psi_3 \tilde{\Theta}_{\alpha'}' \chi \] (B.27)
GHP expansion of $\tilde{f}_{\alpha'}$, $\Theta_{\alpha'}$, $\tilde{\Theta}_{\alpha'}$ leads to
\[ \dot{\psi}_4 = -\frac{3}{2} \psi_2 (f_{\sigma'} \tilde{\Theta}_{\sigma'} + \tilde{f}_{\sigma'} \Theta_{\sigma'} + 2 \psi_2 + 4 \Lambda) \chi + \frac{1}{2} (\tilde{\Theta}_{\alpha'} - 4 \tilde{f}_{\alpha'} ) \psi_3 \tilde{\Theta}_{\alpha'}' \chi \] (B.28)
Comparison to the projected Killing vector defined in (3.20) shows (4.51).
