Dedicated to N.N.Ganikhodjaev on the occasion of his 60th birthday

Abstract: We consider a finite range lattice models on Cayley tree with two basic properties: the existence of only a finite number of ground states and with Peierls type condition. We define notion of a contour for the model on the Cayley tree. By a contour argument we show the existence of $s$ different (where $s$ is the number of ground states) Gibbs measures.

1 Introduction

This paper is a continuation of our previous papers [19]-[21] devoted to the introduction of a contour method on Cayley tree (Bethe lattice [1]). The lattice spin systems are large class of systems considered in statistical mechanics. Some of them have a real physical meaning, others are studied as suitable simplified models of more complicated systems.

One of the key problems related to lattice spin systems is the description of the set of Gibbs measures. The structure of the lattice plays an important role in the investigations of spin systems. For example in order to study the phase transition problem (non-uniqueness of Gibbs measure) for a system on $\mathbb{Z}^d$ and on Cayley tree, respectively, there are two different methods: contour method (Pirogov-Sinai theory) on $\mathbb{Z}^d$ (see e.g. [2],[5],[7],[14],[16],[17],[22],[24],[25]) and Markov random field theory on Cayley tree (see e.g. [3],[4],[8-10],[13],[18],[23]).

In the Pirogov-Sinai theory configurations can be described by contours which satisfy Peierls condition. This theory provides tools for a very detailed knowledge of the structure of Gibbs measures in a region in the relevant parameters space (see e.g. [22]). The Pirogov-Sinai theory is a low temperature expansion which enables to control the entropic fluctuations from the ground states, its natural setup being the lattice systems. But the theory is not limited to such cases and it has been applied to a great variety of situations, covering various types of phase transitions. (see e.g. [6] for details).

Note, that Pirogov-Sinai theory on Cayley tree is not simply applicable and not much work has been done to develop contour methods on trees ([19]-[21]). While studying models with the interaction radius $r \geq 2$ on Cayley tree to describe of Gibbs measures by the (above mentioned) method of Markov random field theory becomes difficult, since in this case there appears a set of nonlinear equations which can not solved analytically. To avoid this problem it looks very useful to develop a contour method (Pirogov-Sinai theory) on Cayley tree.

This paper presents a contour method for a general model with the interaction radius $r$ ($1 \leq r < \infty$) and with a finite number of ground states on the Cayley tree of order $k \geq 2$. For

\footnote{The work supported by NATO Reintegration Grant: FEL.RIG.980771.}
\(k = 1\) this method was developed in [19] for a model with nonhomogeneous nearest-neighbor interactions.

The paper is organized as follows. In section 2 we give all necessary definitions (Cayley tree, model, Gibbs measure etc). In section 3 under some assumptions on the model (Assumptions A1-A3) we prove the Peierls condition. Section 4 devoted to definition and properties of contours on Cayley tree. In section 5 by a contour argument we show the existence of \(s\) different (where \(s\) is the number of ground states) Gibbs measures for the model under consideration on the Cayley tree of order \(k \geq 2\). In the last section we check our assumptions A1-A3 for several examples of models.

2 Definitions

2.1. The Cayley tree. The Cayley tree \(\Gamma^k\) (See [1]) of order \(k \geq 1\) is an infinite tree, i.e., a graph without cycles, from each vertex of which exactly \(k+1\) edges issue. Let \(\Gamma^k = (V, L, i)\), where \(V\) is the set of vertices of \(\Gamma^k\), \(L\) is the set of edges of \(\Gamma^k\) and \(i\) is the incidence function associating each edge \(l \in L\) with its endpoints \(x, y \in V\). If \(i(l) = \{x, y\}\), then \(x\) and \(y\) are called nearest neighboring vertices, and we write \(l = \langle x, y \rangle\).

The distance \(d(x, y), x, y \in V\) on the Cayley tree is defined by the formula

\[
d(x, y) = \min \{d(\exists x = x_0, x_1, ..., x_d = y \in V \text{ such that } \langle x_0, x_1\rangle, ..., \langle x_{d-1}, x_d \rangle)\}.
\]

For the fixed \(x^0 \in V\) we set \(W_n = \{x \in V \mid d(x, x^0) = n\}\),

\[
V_n = \{x \in V \mid d(x, x^0) \leq n\}, \quad L_n = \{l = \langle x, y \rangle \in L \mid x, y \in V_n\}.
\]

Denote \(|x| = d(x, x^0), x \in V\).

It is known (see e.g. [8]) that there exists a one-to-one correspondence between the set \(V\) of vertices of the Cayley tree of order \(k \geq 1\) and the group \(G_k\) of the free products of \(k+1\) cyclic groups \(\langle e, a_i \rangle, i = 1, ..., k+1\) of the second order (i.e. \(a_i^2 = e, a_i^{-1} = a_i\)) with generators \(a_1, a_2, ..., a_{k+1}\).

Let us define a graph structure on \(G_k\) as follows. Vertices which correspond to the ”words” \(g, h \in G_k\) are called nearest neighbors if either \(g = ha_i\) or \(h = ga_j\) for some \(i\) or \(j\). The graph thus defined is a Cayley tree of order \(k\).

For \(g_0 \in G_k\) a left (resp. right) transformation shift on \(G_k\) is defined by

\[
F_{g_0}h = g_0h \quad \text{(resp. } F_{g_0}h = hg_0)\quad \forall h \in G_k.
\]

It is easy to see that the set of all left (resp. right) shifts on \(G_k\) is isomorphic to \(G_k\).

2.2. Configuration space and the model. For \(A \subseteq V\) a spin configuration \(\sigma_A\) on \(A\) is defined as a function \(x \in A \rightarrow \sigma_A(x) \in \Phi = \{1, 2, ..., q\}\); the set of all configurations coincides with \(\Omega_A = \Phi^A\). We denote \(\Omega = \Omega_V\) and \(\sigma = \sigma_V\). Also we define a periodic configuration as a configuration \(\sigma \in \Omega\) which is invariant under a subgroup of shifts \(G^*_k \subseteq G_k\) of finite index.

More precisely, a configuration \(\sigma \in \Omega\) is called \(G^*_k\)-periodic if \(\sigma(F_yx) = \sigma(x)\) for any \(x \in G_k\) and \(y \in G^*_k\).
For a given periodic configuration the index of the subgroup is called the \textit{period of the configuration}. A configuration that is invariant with respect to all shifts is called \textit{translation-invariant}.

The energy of the configuration \( \sigma \in \Omega \) is given by the formal Hamiltonian

\[
H(\sigma) = \sum_{A \subset V : \text{diam}(A) \leq r} I(\sigma_A)
\]  

(2.1)

where \( r \in \mathbb{N} = \{1, 2, \ldots\} \), \( \text{diam}(A) = \max_{x,y \in A} d(x, y) \), \( I(\sigma_A) : \Omega_A \to R \) is a given translation invariant potential i.e. \( I(\sigma_A) = I(\sigma_{F_y A}) \) for any \( y \in G_k \). Here \( \sigma_{F_y A} = \{ \sigma(F_y x), x \in A \} \).

Fix \( r \in \mathbb{N} \) and put \( r' = \lceil \frac{r+1}{2} \rceil \), where \( \lceil a \rceil \) is the integer part of \( a \).

Denote by \( M_r \) the set of all balls \( b_r(x) = \{ y \in V : d(x, y) \leq r' \} \) with radius \( r' \) i.e. \( M_r = \{ b_r(x) : x \in V \} \).

For \( A \subset V \) with \( \text{diam}(A) \leq r \) denote

\[
n(A) = |\{ b \in M_r : A \subset b \}|,
\]

where \( |A| \) stands for the number of elements of a set \( A \).

The Hamiltonian (2.1) can be written as

\[
H(\sigma) = \sum_{b \in M_r} U(\sigma_b),
\]

(2.2)

where \( U(\sigma_b) = \sum_{A \subset b} \frac{I(\sigma_A)}{n(A)} \).

For a finite domain \( D \subset V \) with the boundary condition \( \varphi_{D^c} \) given on its complement \( D^c = V \setminus D \), the conditional Hamiltonian is

\[
H(\sigma_D | \varphi_{D^c}) = \sum_{b \in M_r, b \cap D \neq \emptyset} U(\sigma_b),
\]

(2.3)

where

\[
\sigma_b(x) = \begin{cases} \sigma(x) & \text{if } x \in b \cap D \\ \varphi(x) & \text{if } x \in b \cap D^c. \end{cases}
\]

2.3. \textit{The ground state}. A \textit{ground state} of (2.2) is a configuration \( \varphi \) in \( \Gamma^k \) whose energy cannot be lowered by changing \( \varphi \) in some local region. We assume that (2.2) has a finite number of translation-periodic (i.e. invariant under the action of some subgroup of \( G_k \) of finite index) ground states. By a standard trick of partitioning the tree into disjoint sets \( Q(x) \) centered at \( x \in G_k^* \) (the corresponding subgroup of finite index) and enlarging the spin space from \( \Phi \) to \( \Phi^Q \) one can transform the model above into a model with only translation-invariant or nonperiodic ground states. Such a transformation was considered in [12] for models on \( \mathbb{Z}^d \). Hence, without loss of generality, we assume translation-invariance instead of translational-periodic and we permute the spin so that the set of ground states of the model be \( GS = GS(H) = \{ \sigma^{(i)}, i = 1, 2, \ldots, s \}, 1 \leq s \leq q \) with \( \sigma^{(i)}(x) = i \) for any \( x \in V \).

2.4. \textit{Gibbs measure}. We consider a standard sigma-algebra \( \mathcal{B} \) of subsets of \( \Omega \) generated by cylinder subsets; all probability measures are considered on \( (\Omega, \mathcal{B}) \). A probability measure \( \mu \) is
called a *Gibbs measure* (with Hamiltonian $H$) if it satisfies the DLR equation: \( \forall \, n = 1, 2, \ldots \) and \( \sigma_n \in \Omega_{V_n} \):

\[
\mu \left( \left\{ \sigma \in \Omega : \sigma|_{V_n} = \sigma_n \right\} \right) = \int_{\Omega} \mu(\text{d}\omega)\nu^\varphi_n(\sigma_n),
\]

(2.4)

where \( \nu^\varphi_n \) is the conditional probability:

\[
\nu^\varphi_n(\sigma_n) = \frac{1}{Z_{n,\varphi}} \exp \left( -\beta H(\sigma_n|\varphi^\kappa_{V_n}) \right).
\]

(2.5)

Here \( \beta = \frac{1}{T}, T > 0 \) is the temperature and \( Z_{n,\varphi} \) stands for the partition function in \( V_n \), with the boundary condition \( \varphi \):

\[
Z_{n,\varphi} = \sum_{\sigma_n \in \Omega_{V_n}} \exp \left( -\beta H(\sigma_n|\varphi^\kappa_{V_n}) \right).
\]

(2.6)

3 The Peierls condition

Denote by \( U \) the set of all possible values of \( U(\sigma_b) \) for any configuration \( \sigma_b, b \in M_r \). Since \( r < +\infty \) we have \( |U| < +\infty \). Put \( U^{\text{min}} = \min\{U : U \in U\} \) and

\[
\lambda_0 = \min \left\{ U \setminus \{ U \in U : U = U^{\text{min}} \} \right\} - U^{\text{min}}.
\]

(3.1)

The important assumptions of this paper are the following:

**Assumption A1.** The set of all ground states is \( GS = \{ \sigma^{(i)}, i = 1, 2, \ldots, s \}, 1 \leq s \leq q \).

**Assumption A2.** \( \lambda_0 > 0 \).

**Assumption A3.** Each \( \varphi \in GS \) satisfies

\[
U(\varphi_b) = U^{\text{min}} \text{ for every } b \in M_r.
\]

(3.2)

**Remark.** If a configuration \( \sigma \) satisfies (3.2) i.e. \( U(\sigma_b) = U^{\text{min}} \) for all \( b \in M_r \) then it is a ground state. Moreover for Hamiltonians on \( Z^d \) it is well known that a configuration is a ground state if and only if the condition (3.2) is satisfied (see e.g. [22]). But such a fact is not clear for Hamiltonians on the Cayley tree, since the tree is a non-amenable graph i.e. \( \inf\{ |\text{boundary of } W| : W \subset V, 0 < |W| < \infty \} > 0 \) for \( k \geq 2 \) (see e.g. [1], [11]).

The *relative Hamiltonian* is defined by

\[
H(\sigma, \varphi) = \sum_{b \in M_r} (U(\sigma_b) - U(\varphi_b)).
\]

**Definition 3.1.** Let \( GS \) be the complete set of all ground states of the relative Hamiltonian \( H \). A ball \( b \in M_r \) is said to be an improper ball of the configuration \( \sigma \) if \( \sigma_b \neq \varphi_b \) for any \( \varphi \in GS \). The union of the improper balls of a configuration \( \sigma \) is called the boundary of the configuration and denoted by \( \partial(\sigma) \).

**Definition 3.2.** The relative Hamiltonian \( H \) with the set of ground states \( GS \) satisfies the Peierls condition if for any \( \varphi \in GS \) and any configuration \( \sigma \) coinciding almost everywhere with \( \varphi \) (i.e. \( |\{x \in V : \sigma(x) \neq \varphi(x)\}| < \infty \))

\[
H(\sigma, \varphi) \geq \lambda|\partial(\sigma)|,
\]
where $\lambda$ is a positive constant which does not depend on $\sigma$, and $|\partial(\sigma)|$ is the number of balls in $\partial(\sigma)$.

**Theorem 3.3.** If assumptions A1-A3 are satisfied then the Peierls condition holds.

**Proof.** Suppose $\sigma$ coincides almost everywhere with a ground state $\varphi \in GS$ then we have $U(\sigma_b) - U^{\min} \geq \lambda_0$ for any $b \in \partial(\sigma)$ since $\varphi$ is a ground state. Thus

$$H(\sigma, \varphi) = \sum_{b \in M_r} (U(\sigma_b) - U(\varphi_b)) = \sum_{b \in \partial(\sigma)} (U(\sigma_b) - U^{\min}) \geq \lambda_0 |\partial(\sigma)|.$$ 

Therefore, the Peierls condition is satisfied for $\lambda = \lambda_0$. The theorem is proved.

4 **Contours on Cayley tree**

Let $\Lambda \subset V$ be a finite set. Let $\sigma_{\Lambda}^{(i)} \equiv i$, $i = 1, \ldots, s$ be a constant configuration outside of $\Lambda$. For each $i$ we extend the configuration $\sigma_{\Lambda}$ inside $\Lambda$ to the entire tree by the $i$th constant configuration and denote it by $\sigma_{\Lambda}^{(i)}$. The set of such configurations we denote by $\Omega_{\Lambda}^{(i)}$.

Now we are going to recall a construction of the subcontours (see [20]). Note that our definition (see definition 4.3 below) of a contour depends on $r$, at $r = 1$ we get a contour defined in [20]. But the definition of a subcontour does not depend on $r$.

Consider $V_n$ and for a given configuration $\sigma_{\Lambda}^{(i)} \in \Omega_{\Lambda}^{(i)}$ denote $V_n^{(j)} \equiv V_n(\sigma_{\Lambda}^{(i)}) = \{t \in V_n : \sigma_{\Lambda}^{(i)}(t) = j\}, j = 1, \ldots, q, j \neq i$. Let $G^{n,j} = (V_n^{(j)}, L_n^{(j)})$ be a graph such that

$$L_n^{(j)} = \{l = < x, y > \in L : x, y \in V_n^{(j)}\}, \ j = 1, \ldots, q, j \neq i.$$ 

It is clear, that for a fixed $n$ the graph $G^{n,j}$ contains a finite number ($= m$) of maximal connected subgraphs $G_p^{m,j}$ i.e.

$$G^{n,j} = \{G_1^{m,j}, \ldots, G_m^{m,j}\}, \ G_p^{m,j} = (V_{n,p}^{(j)}, L_{n,p}^{(j)}), \ p = 1, \ldots, m; j \neq i.$$ 

Here $V_{n,p}^{(j)}$ and $L_{n,p}^{(j)}$ are the set of vertexes and edges of $G_p^{m,j}$, respectively.

Two edges $l_1, l_2 \in L, \ (l_1 \neq l_2)$ are called nearest neighboring edges if $|i(l_1) \cap i(l_2)| = 1$, and we write $< l_1, l_2 > 1.$

For any subgraph $K \subset \Gamma^k$ denote by $E(K)$ the set of edges, by $V(K)$ the set of vertices of $K$ and

$$B(K) = \{l \in L \setminus E(K) : \exists l_1 \in E(K) \text{ such that } < l, l_1 > 1\}.$$ 

**Definition 4.1.** An edge $l = < x, y > \in L_{n+1}$ is called a boundary edge of the configuration $\sigma_{V_n}^{(i)}$ if $\sigma_{V_n}^{(i)}(x) \neq \sigma_{V_n}^{(i)}(y)$.

The set of boundary edges of $\sigma_{V_n}^{(i)}$ is called edge boundary $\partial_1(\sigma_{V_n}^{(i)}) \equiv \partial_1$ of the configuration.

The (finite) set $B(G_p^{m,j}), j = 1, \ldots, q, j \neq i, p = 1, \ldots, m$ (together with a given configuration on it) is called subcontour of the boundary $\partial_1$.

The set $V_{n,p}^{(j)}, j = 1, \ldots, q, j \neq i, p = 1, \ldots, m$ is called interior of $B(G_p^{m,j})$, and is denoted by $\text{Int}B(G_p^{m,j})$. The set of edges from a subcontour $T$ is denoted by $\text{supp}T$. The configuration $\sigma_{V_n}^{(i)}$
takes the same value \( j \) at all points of the connected component \( G_p^{n,j} \). This value \( v = v(G_p^{n,j}) \) is called the mark of the subcontour and denoted by \( v(T) \), where \( T = B(G_p^{n,j}) \).

The collection of subcontours \( \tau = \tau(\sigma_{V_n}^{(i)}) = \{ T_p \} \) generated by the edge boundary \( \partial_1 = \partial_1(\sigma_{V_n}^{(i)}) \) of \( \sigma_{V_n}^{(i)} \) has the following properties

(a) Every subcontour \( T \in \tau \) lies inside the set \( V_{n+1} \).

(b) For every two subcontours \( T_1, T_2 \in \tau \) their supports \( \text{supp} T_1 \) and \( \text{supp} T_2 \) satisfy \( |\text{supp} T_1 \cap \text{supp} T_2| \in \{0, 1\} \).

(c) For any two subcontours \( T_1, T_2 \in \tau \) with \( |\text{supp} T_1 \cap \text{supp} T_2| = 1 \) we have \( v(T_1) \neq v(T_2) \).

The distance \( \text{dist}(T_1, T_2) \) is defined by

\[
\text{dist}(T_1, T_2) = \min_{x \in V(T_1), y \in V(T_2)} d(x, y),
\]

where \( d(x, y) \) is the distance between \( x, y \in V \) (see section 2.1).

Recall \( r' = \lfloor \frac{r+1}{2} \rfloor \).

**Definition 4.2.** The subcontours \( T_1, T_2 \) are called adjacent if \( \text{dist}(T_1, T_2) \leq 2(r' - 1) \). A set of subcontours \( \mathcal{A} \) is called connected if for any two subcontours \( T_1, T_2 \in \mathcal{A} \) there is a collection of subcontours \( T_1 = \tilde{T}_1, \tilde{T}_2, ..., \tilde{T}_l = T_2 \) in \( \mathcal{A} \) such that for each \( i = 1, ..., l - 1 \) the subcontours \( \tilde{T}_i \) and \( \tilde{T}_{i+1} \) are adjacent.

**Definition 4.3.** Any maximal connected set (component) of subcontours is called contour of the set \( \partial_1 \).

For contour \( \gamma = \{ T_p \} \) denote \( \text{Int} \gamma = \cup_p \text{Int} T_p \).

**Remarks.** 1. Note that Definition 4.3 of contours coincides with the Definition 2 of [20] for \( r = 1 \). But Definition 4.3 is better than corresponding Definition 11 of [21] for \( r = 2 \). Because, for \( r = 2 \) from the definition 4.2 we have \( \text{dist}(T_1, T_2) = 0 \) i.e. the subcontours do not interact if the distance between them is \( \geq 1 \) but in [21] the condition was like \( \text{dist}(T_1, T_2) \leq 2 \).

2. Our definition of a contour is slightly different from the definition of contour of Hamiltonians on \( Z^d, d \geq 2 \) (see [17], [22]). For any two contours \( \gamma, \gamma' \) we have \( \text{dist}(\gamma, \gamma') > 2(r' - 1) \). Thus our contours do not interact. This means that for any \( \sigma \in \Omega \) there is no a ball \( b \in \partial(\sigma) \) with \( b \cap \gamma \neq \emptyset \) and \( b \cap \gamma' \neq \emptyset \). Such property allows as to use a contour-removal operation. This operation is similar to the one in ordinary Peiers argument [7]: Given a family of contours defining a configuration \( \sigma \in \Omega_\Lambda^{(i)} \), the family obtained by omitting one of them is also the family of contours of a (different) configuration in \( \Omega_\Lambda^{(i)} \). There is an algorithm of the contour-removal operation to obtain a new configuration as follows. Take the configuration \( \sigma \) and change all the spins in the interior of \( \gamma \) (which must be removed) to value \( i \). This makes \( \gamma \) disappear, but leaves intact the other contours.

For a given (sub)contour \( \gamma \) denote

\[
\text{imp} \gamma = \{ b \in \partial : b \cap \gamma \neq \emptyset \}, \quad |\gamma| = |\text{imp} \gamma|.
\]

By the construction we have \( \text{imp} \gamma \cap \text{imp} \gamma' = \emptyset \) for any contours \( \gamma \neq \gamma' \).
For $A \subseteq V$ denote
\[ C(A) = \{ b \in M_r : b \cap A \neq \emptyset \}; \]
\[ D(A) = \{ x \in V \setminus A : \exists y \in A, \text{ such that } < x, y > \}. \]

**Lemma 4.4.** Let $K$ be a connected subgraph of the Cayley tree $\Gamma^k$ of order $k \geq 2$, such that $|V(K)| = n$, then
(i). $|D(V(K))| = (k - 1)n + 2$.
(ii). $|C(V(K))| = k^{r'} - ((k - 1)n + 2)$.

**Proof.** (i). We shall use the induction over $n$. For $n = 1$ and $2$ the assertion is trivial. Assume for $n = m$ the lemma is true i.e. from $|V(K)| = m$ follows that $|D(V(K))| = (k - 1)m + 2$. We shall prove the assertion for $n = m + 1$ i.e. for $\tilde{K} = K \cup \{ x \}$. Since $\tilde{K}$ is connected graph we have $x \in D(V(K))$ and there is a unique $y \in S_1(x) = \{ u \in V : d(x, u) = 1 \}$ such that $y \in V(K)$. Thus $D(V(\tilde{K})) = (D(V(K)) \setminus \{ x \}) \cup (S_1(x) \setminus \{ y \})$. Consequently,
\[ |D(V(\tilde{K}))| = |D(V(K))| - 1 + k = (k - 1)(m + 1) + 2. \]

(ii). Using (i) we obtain $|C(V(K))| = u_{r'}$, where $u_{r'}$ is the last term of the collection $u_1, u_2, \ldots, u_{r'}$ which is defined by the following recurrent relations
\[ u_l = 2 + (k - 1) \sum_{i=0}^{l-1} u_i, \quad l = 1, 2, \ldots, r', \quad u_0 = n. \] (4.1)
Iterating (4.1) we get $u_1 = (k - 1)n + 2$, $u_2 = k((k - 1)n + 2)$, then using the induction over $l$ we obtain $u_l = k^{l-1}((k - 1)n + 2)$. This completes the proof.

Let us define a graph structure on $M_r$ as follows. Two balls $b, b' \in M_r$ are connected by an edge if their centers are nearest neighbors. Denote this graph by $G(M_r)$. Note that the graph $G(M_r)$ is a Cayley tree of order $k \geq 1$. Here the vertices of this graph are balls of $M_r$. Thus Lemma 1.2 of [5] can be reformulated as follows

**Lemma 4.5.** Let $\tilde{N}_{n, G}(x)$ be the number of connected subgraphs $G' \subset G(M_r)$ with $x \in V(G')$ and $|V(G')| = n$. Then
\[ \tilde{N}_{n, G}(x) \leq (ek)^n. \]

For $x \in V$ we will write $x \in \gamma$ if $x \in V(\gamma)$.
Denote $N_l(x) = |\{ \gamma : x \in \gamma, |\gamma| = l \}|$, where as before $|\gamma| = |\text{imp}\gamma|$.

**Lemma 4.6.** If $k \geq 2$ then
\[ N_l(x) \leq C_0 \theta^l, \] (4.2)
where $C_0 = 1 + \frac{k+1}{k}(k^{r'} - 1)$, $\theta = \theta(k, r) = (2ek)^{2(k+1)(r'-1)k^{r'-1}+2}$.

**Proof.** Denote by $K_\gamma$ the minimal connected subgraph of $\Gamma^k$, which contains a contour $\gamma = \{ \gamma_1, \ldots, \gamma_m \}, m \geq 1$, where $\gamma_i$ is subcontour. Put
\[ M_{r, \gamma}^- = \{ x \in \text{Int}\gamma : \text{dist}(x, V \setminus \text{Int}\gamma) > r' \}; \]
\[M^0_{r,\gamma} = \{x \in \text{Int} \gamma : \text{dist}(x, V \setminus \text{Int} \gamma) \leq r'\};\]
\[M^+_{r,\gamma} = \{x \in V \setminus \text{Int} \gamma : \text{dist}(x, \text{Int} \gamma) \leq r'\};\]
\[Y_\gamma = V(K_\gamma) \setminus (\text{Int} \gamma \cup D(\text{Int} \gamma)).\]

We have
\[|\gamma| = |M^0_{r,\gamma}| + |M^+_{r,\gamma}|;\]
\[|C(V(K_\gamma))| \leq |M^-_{r,\gamma}| + |\gamma| + |C(Y_\gamma)|. \quad (4.3)\]

For any \(k \geq 2, r \geq 1\) by Lemma 4.4 we have
\[|M^-_{r,\gamma}| = \frac{|D(M^-_{r,\gamma})| - 2}{k - 1} < |D(M^-_{r,\gamma})| \leq |M^0_{r,\gamma}| < |\gamma|. \quad (4.4)\]

Note that \(0 \leq |Y_\gamma| \leq 2(m - 1)(r' - 1).\) Thus
\[|C(T_\gamma)| \leq 2(m - 1)(r' - 1)|C(\{y\})|, \quad (4.5)\]

where \(y\) is an arbitrary point of \(Y_\gamma\). By Lemma 4.4. we have \(|C(\{y\})| = k^{r'-1}(k + 1)\) since \(|V(\{y\})| = 1\). Hence from (4.3)-(4.5) we get
\[|C(V(K_\gamma))| < 2|\gamma| + 2(m - 1)(r' - 1)(k + 1)k^{r'-1}. \quad (4.6)\]

Since \(\gamma\) contains \(m\) subcontours we have \(m < |\gamma|\). A combinatorial calculations show that
\[N_l(x) \leq C_0 \sum_{m=1}^{l} \left(2l + 2k^{r'-1}(k + 1)(r' - 1)(m - 1)\right) N_{2l+2k^{r'-1}(k+1)(r'-1)(m-1),\Gamma_k} (b_x), \quad (4.7)\]

where \(N_l, \Gamma_k\) is defined in Lemma 4.5 and \(b_x\) is a ball \(b \in M_r\) such that \(x \in b\). Using inequality \(\binom{n}{l} \leq 2^{n-1}, l \leq n\) and Lemma 4.5 from (4.7) we get (4.2). The lemma is proved.

5 Non-uniqueness of Gibbs measure

For \(\sigma_n \in \Omega_{V_n}^{(i)}\) the conditional Hamiltonian (2.3) has the form
\[H(\sigma_n) \equiv H(\sigma_n|\sigma_{V_n}^i = i) = \sum_{b \in M_r, b \cap V_n \neq \emptyset} U(\sigma_n, b) = \sum_{b \in \partial(\sigma_n)} (U(\sigma_n, b) - U^\text{min}) + |C(V_n)|U^\text{min}, \quad (5.1)\]

where \(\sigma_{n,b} = (\sigma_n)_b\).

The Gibbs measure on the space \(\Omega_{V_n}^{(i)}\) with boundary condition \(\sigma^{(i)}\) is defined as
\[\mu^{(i)}_{n,\beta}(\sigma_n) = Z^{-1}_{n,i} \exp(-\beta H(\sigma_n)), \quad (5.2)\]

where \(Z_{n,i}\) is the normalizing factor.

Let us consider a sequence of balls on \(\Gamma^k\)
\[V_1 \subset V_2 \subset \ldots \subset V_n \subset \ldots, \quad \cup V_n = V,\]
and $s$ sequences of boundary conditions outside these balls:

$$\sigma_n^{(i)} \equiv i, n = 1, 2, \ldots, i = 1, \ldots, s.$$ 

By very similar argument of proof of the lemma 9.2 in [14] one can prove that each of $s$ sequences of measures $\{\mu_{n, \beta, i}, n = 1, 2, \ldots\}, i = 1, \ldots, s$ contains a convergent subsequence.

We denote the corresponding limits by $\mu_{\beta, i}, i = 1, \ldots, s$. Our purpose is to show for a sufficiently large $\beta$ these measures are different.

**Lemma 5.1.** Suppose assumptions A1-A3 are satisfied. Let $\gamma$ be a fixed contour and $p_i(\gamma) = \mu_{\beta, i}(\sigma_n : \gamma \in \partial(\sigma_n))$. Then

$$p_i(\gamma) \leq \exp\{-\beta \lambda_0 |\gamma|\}, \quad (5.3)$$

where $\lambda_0$ is defined by formula (3.1).

**Proof.** Put $\Omega_\gamma = \{\sigma_n \in \Omega_{V_n}^{(i)} : \gamma \subset \partial(\sigma_n)\}$, $\Omega_\gamma^0 = \{\sigma_n : \gamma \cap \partial = \emptyset\}$ and define a (contour-removal) map $\chi_\gamma : \Omega_\gamma \to \Omega_\gamma^0$ by

$$\chi_\gamma(\sigma_n)(x) = \begin{cases} i & \text{if } x \in \text{Int} \gamma \\ \sigma_n(x) & \text{if } x \notin \text{Int} \gamma. \end{cases}$$

For a given $\gamma$ the map $\chi_\gamma$ is one-to-one map. For any $\sigma_n \in \Omega_{V_n}^{(i)}$ we have

$$|\partial(\sigma_n)| = |\partial(\chi_\gamma(\sigma_n))| + |\gamma|.$$ 

Consequently, using (5.1) one finds

$$p_i(\gamma) = \frac{\sum_{\sigma_n \in \Omega_\gamma} \exp\{-\beta \sum_{b \in \partial(\sigma_n)} (U(\sigma_{n,b}) - U^{\text{min}})\}}{\sum_{\sigma_n} \exp\{-\beta \sum_{b \in \partial(\sigma_n)} (U(\sigma_{n,b}) - U^{\text{min}})\}} \leq \frac{\sum_{\sigma_n \in \Omega_\gamma} \exp\{-\beta \sum_{b \in \partial(\sigma_n)} (U(\sigma_{n,b}) - U^{\text{min}})\}}{\sum_{\sigma_n \in \Omega_\gamma^0} \exp\{-\beta \sum_{b \in \partial(\sigma_n)} (U(\sigma_{n,b}) - U^{\text{min}})\}} = \frac{\sum_{\sigma_n \in \Omega_\gamma} \exp\{-\beta \sum_{b \in \partial(\chi_\gamma(\sigma_n))} (U(\chi_\gamma(\sigma_n)) - U^{\text{min}})\}}{\sum_{\sigma_n \in \Omega_\gamma} \exp\{-\beta \sum_{b \in \partial(\sigma_n)} (U(\chi_\gamma(\sigma_n)) - U^{\text{min}})\}}. \quad (5.4)$$

Since $\sigma_{n,b} = \chi_\gamma(\sigma_{n,b})$, for any $b \in \partial(\sigma_n) \setminus \text{imp} \gamma$ we have

$$\sum_{b \in \partial(\sigma_n)} (U(\sigma_{n,b}) - U^{\text{min}}) = S_1 + S_2, \quad (5.5)$$

where $S_1 = \sum_{b \in \partial(\chi_\gamma(\sigma_n))}(U(\sigma_{n,b}) - U^{\text{min}})$; $S_2 = \sum_{b \in \text{imp} \gamma}(U(\sigma_{n,b}) - U^{\text{min}})$.

Note that for a fixed $\gamma$ the sum $S_2$ does not depend on configuration $\sigma_n \in \Omega_\gamma$. Indeed, by our construction $\gamma$ is a contour of $\partial(\sigma_n)$ iff $\sigma_n(x) = i$ for any $x \in M^+_{\gamma, \gamma}$. Consequently, $\text{imp} \gamma$ and $S_2$ do not depend on $\sigma_n \in \Omega_\gamma$.

Hence, (5.4) implies that

$$p_i(\gamma) \leq \exp(-\beta S_2). \quad (5.6)$$
By assumptions A1-A3 we have \( U(\sigma_{n,b}) - U^\text{min} \geq \lambda_0 > 0 \), for any \( b \in \text{imp}\gamma \). Thus from (5.6) one gets (5.3). The lemma is proved.

Now using Lemmas 4.6 and 5.1 by very similar argument of [20] one can prove the following

**Lemma 5.2.** If assumptions A1-A3 are satisfied then for fixed \( x \in \Lambda \) uniformly by \( \Lambda \) the following relation holds

\[
\mu^x_\beta(\sigma : \sigma(x) = j) \rightarrow 0, j \neq i \quad \text{as} \quad \beta \rightarrow \infty.
\]

This lemma implies the main result, i.e.

**Theorem 5.3.** If A1-A3 are satisfied then for all sufficiently large \( \beta \) there are at least \( s (= \text{number of ground states}) \) Gibbs measures for the model (2.2) on Cayley tree of order \( k \geq 2 \).

6 Examples

In this section we shall give several examples with the properties A1-A3.

6.1. \( q \)-component models. Note that under some suitable conditions on the parameters of \( q \)-component models (with nearest neighbor interactions) on Cayley tree (see [20]) the assumptions A1-A3 are satisfied. In particular, the ferromagnetic Ising, Potts and SOS models have the properties A1-A3.

6.2. The Potts model with competing interactions \((k = 2, q = 3)\). Consider the Hamiltonian

\[
H(\sigma) = J_1 \sum_{\langle x,y \rangle, x,y \in V} \delta_{\sigma(x)\sigma(y)} + J_2 \sum_{x,y \in V : d(x,y) = 2} \delta_{\sigma(x)\sigma(y)},
\]

where \( J = (J_1, J_2) \in \mathbb{R}^2 \), \( \sigma(x) \in \Phi = \{1, 2, ..., q\} \) and \( \delta \) is the Kronecker’s symbol i.e.

\[
\delta_{u,v} = \begin{cases} 1 & \text{if } u = v \\ 0 & \text{if } u \neq v. \end{cases}
\]

Note that the Ising model with competing interactions (see [21]) is a particular case of the model (6.1). For the model (6.1) with \( k = 2, q = 3 \) we put

\[
U(\sigma_b) \equiv U(\sigma_b, J) = \frac{1}{2} J_1 \sum_{\langle x,y \rangle, x,y \in b} \delta_{\sigma(x)\sigma(y)} + J_2 \sum_{x,y \in b : d(x,y) = 2} \delta_{\sigma(x)\sigma(y)}.
\]

A simple calculations show that

\[
U = \{U(\sigma_b)\} = \{\frac{3}{2} J_1 + 3 J_2, \ J_1 + J_2, \ 3 J_2, \ \frac{1}{2} J_1, \ J_2, \ \frac{1}{2} J_1 + J_2\}.
\]

By similar argument of [21] (pages 221-223) one can show that for the model (6.1) the assumptions A1-A3 are satisfied if \( J \in \{J \in \mathbb{R}^2 : J_1 < 0, J_1 + 4 J_2 < 0\} \).

6.3. A model with the interaction radius \( r \geq 1 \). For \( A \subseteq V \) let us define a generalized Kronecker symbol as the function \( U_0(\sigma_A) : \Omega_A \rightarrow \{|A| - 1, |A| - 2, ..., |A| - \min\{|A|, |\Phi|\}\} \) by

\[
U_0(\sigma_A) = |A| - |\sigma_A \cap \Phi|,
\]

10
Note that if $|A| = 2$, say, $A = \{x, y\}$, then $U_0(\{\sigma(x), \sigma(y)\}) = \delta_{\sigma(x), \sigma(y)}$. Now consider the Hamiltonian

$$H(\sigma) = -J \sum_{b \in M_r} U_0(\sigma_b), \quad (6.4)$$

where $J \in R$.

It is easy to see that if $J > 0$ then the assumptions A1-A3 are satisfied for any $r \geq 1$ and $k \geq 2$.
