HOMOLOGY COBORDISM INVARIANTS AND THE COCHRAN-ORR-TEICHNER FILTRATION OF THE LINK CONCORDANCE GROUP

SHELLY L. HARVEY†

Abstract. For any group $G$, we define a new characteristic series related to the derived series, that we call the torsion-free derived series of $G$. Using this series and the Cheeger-Gromov $\rho$-invariant, we obtain new real-valued homology cobordism invariants $\rho_n$ for closed $(4k - 1)$-dimensional manifolds. For 3-dimensional manifolds, we show that $\{\rho_n|n \in \mathbb{N}\}$ is a linearly independent set and for each $n \geq 0$, the image of $\rho_n$ is an infinitely generated and dense subset of $\mathbb{R}$.

In their seminal work on knot concordance, T. Cochran, K. Orr, and P. Teichner define a filtration $F_m(n)$ of the $m$-component (string) link concordance group, called the $(n)$-solvable filtration. They also define a grope filtration $G_m(n)$. We show that $\rho_n$ vanishes for $(n + 1)$-solvable links. Using this, and the non-triviality of $\rho_n$, we show that for each $m \geq 2$, the successive quotients of the $(n)$-solvable filtration of the link concordance group contain an infinitely generated subgroup. We also establish a similar result for the grope filtration. We remark that for knots ($m = 1$), the successive quotients of the $(n)$-solvable filtration are known to be infinite. However, for knots, it is unknown if these quotients have infinite rank when $n \geq 3$.

1. Introduction

The main objective of this paper is to investigate the set of 3-dimensional manifolds up to homology cobordism. To do this, we define, for each $n \in \mathbb{N}$, an invariant of $(4k - 1)$-dimensional manifolds ($k \geq 1$) that we call $\rho_n$. Loosely speaking, $\rho_n(M)$ is defined as a signature defect closely associated to a term of the torsion-free derived series of $\pi_1(M)$ and (for smooth manifolds) can be interpreted as the Cheeger-Gromov invariant of $M$ associated to the $n^{th}$ torsion-free derived regular cover of $M$. Using a derived version of Stallings’ Theorem [6], we show that $\rho_n$ is an invariant of homology cobordism whereas the Cheeger-Gromov $\rho$ invariant associated to an arbitrary cover is only a priori a homeomorphism invariant.

Theorem 4.2 If $M_1^{4k-1}$ is rationally homology cobordant to $M_2^{4k-1}$ ($k \geq 1$) then $\rho_n(M_1) = \rho_n(M_2)$.

To define the invariant $\rho_n$, we first define a new characteristic series $\{G_H^{(n)}\}$ of a group $G$ (Section 2) closely related to the derived series, that we call the torsion-free derived series and establish its basic properties. One should view the torsion-free derived series $\{G_H^{(n)}\}$ of a group $G$ as a series that is closely related to the derived

More specifically, to construct $M$ is independent of the stable nullbordism (which is a series whose successive quotients are torsion-free as abelian groups. signature as follows (see Section 3 for more details). Recall that for any group $\Lambda$, the $U$-torsion-free as $\Lambda$-modules. This can be compared to the rational derived series may seem a bit unwieldy, we focus on the derived series (respectively lower central series) of $\rho$ in the derived series of the fundamental group of $\rho$. Hence one could also study $\rho_n(M)$ (rather than $\rho_n(m)$ or $\rho_n^{cs}$) since it gives an invariant of rational homology cobordism and provides new information about the structure of the $(n)$-solvable and grope filtrations of the (string) link concordance group (see below and Section 6). By contrast, $\rho_n$ is only a homomorphism invariant. One can use Stallings’ Theorem and follow through the proof of Theorem[1.2] to show that $\rho_n^{cs}$ is a homology cobordism invariant. However, we choose to use $\rho_n$ in our work since it is more directly related to the $(n)$-solvable and grope filtrations of the link concordance group than $\rho_n^{cs}$.

We show that the $\rho_n$ are highly non-trivial and independent for 3-manifolds (Section 5). To accomplish this, we construct an infinite family of examples of 3-manifolds $\{M(\eta, K)\}$ that are constructed by a method known as genetic infection. More specifically, to construct $M(\eta, K)$ we start with a 3-manifold $M$ and infect $M$ by a knot $K$ along a curve $\eta$ in the $n$th term of the derived series of the fundamental group of $M$. We prove that $\rho_i(M(\eta, K))$ depends only on $\eta$ and $\rho_0(K)$, where $\rho_0(K)$ is the integral of the Levine-Tristam signatures of $K$.

**Theorem 5.8** Let $M$ be a compact, orientable manifold, $\eta$ an embedded curve in $M$, $K$ a knot in $S^3$, and $P = \pi_1(M)$. If $\eta \in P^{(n)} - P^{(n+1)}$ for some $n \geq 0$ then

$$\rho_i(M(\eta, K)) - \rho_i(M) = \begin{cases} 0 & 0 \leq i \leq n - 1; \\ \rho_0(K) & i \geq n. \end{cases}$$

Let $H^3_\mathbb{Q}$ be the set of $\mathbb{Q}$-homology cobordism classes of closed, oriented 3-dimensional manifolds. Using the set of examples $\{M(\eta, K)\}$ with varying $K$ we establish the following theorem.

**Theorem 5.11** The image of $\rho_n : H^3_\mathbb{Q} \to \mathbb{R}$ is (1) dense in $\mathbb{R}$ and (2) an infinitely generated subgroup of $\mathbb{R}$. 

Moreover, in Theorem 5.13 we show that \( \{ \rho_n \} \) is a linearly independent subset of the vector space of functions on \( H^3_\Omega \).

We remark that S. Chang and S. Weinberger [5] use a similar type of signature defect, one associated to the universal cover of a manifold, to define a homeomorphism invariant \( \tau_{(2)} \) of a \((4k-1)\)-dimensional manifold \((k \geq 1)\). Using \( \tau_{(2)} \) they show that if \( M \) is a \((4k-1)\)-dimensional (smooth) manifold with \( k \geq 2 \) and \( \pi_1(M) \) is not torsion-free then there are infinitely many (smooth) manifolds homotopy equivalent to \( M \) but not homeomorphic to \( M \).

For the rest of the paper, we turn our attention to the study of link concordance. Recall that if two links \( L_1 \) and \( L_2 \) in \( S^3 \) are concordant then \( M_{L_1} \) and \( M_{L_2} \) are homology cobordant where \( M_L \) is the zero surgery on \( L \). We define \( \rho_n(L) = \rho_n(M_L) \) for a link \( L \) in \( S^3 \). Hence, by Theorem 4.12 \( \rho_n \) is a link concordance invariant.

In [11], T. Cochran, K. Orr and P. Teichner defined the \((n)\)-solvable (and grope) filtration of the knot concordance group \( \mathcal{C} \). In [11] and their two subsequent papers, [12, 13], they showed that the quotients \( F_n(\mathcal{C})/F_{n+1}(\mathcal{C}) \) of the \((n)\)-solvable filtration of the knot concordance group are non-trivial. In particular, they showed that for \( n = 1, 2 \), \( F_n(\mathcal{C})/F_{n+1}(\mathcal{C}) \) has infinite rank and for all \( n \geq 3 \), the quotient has rank at least 1. It is still unknown if any of the quotients is infinitely generated for \( n \geq 3 \).

In the current paper, we investigate the \((n)\)-solvable filtration \( F_n(\mathcal{C}) \) of the string link concordance group \( \mathcal{C}(m) \) and the subgroup generated by boundary links \( \mathcal{B}(m) \) for links with \( m \geq 2 \) components. Since connected sum is not a well-defined operation for links, it is necessary to use string links to obtain a group structure. Using \( \rho_n \) we show that, for \( m \geq 2 \), each of the successive quotients of the \((n)\)-solvable filtration of the boundary string link concordance group \( BF_n(\mathcal{C}) \) is infinitely generated.

**Theorem 6.8.** For each \( n \geq 0 \) and \( m \geq 2 \), the abelianization of \( BF_n(\mathcal{C})/BF_{n+1}(\mathcal{C}) \) has infinite rank. In particular, for \( m \geq 2 \), \( BF_n(\mathcal{C})/BF_{n+1}(\mathcal{C}) \) is an infinitely generated subgroup of \( F_n(\mathcal{C})/F_{n+1}(\mathcal{C}) \).

We note the previous theorem holds “modulo local knotting” (see Corollary 6.9), hence this result cannot be obtained using the work of Cochran-Orr-Teichner on knots. We also prove a similar statement for the grope filtrations \( BG_n^m \) and \( G_n^m \) of the boundary and string link concordance groups respectively.

**Theorem 6.13.** For each \( n \geq 1 \) and \( m \geq 2 \), the abelianization of \( BG_n^m/BG_{n+2}^m \) has infinite rank. Hence \( BG_n^m/BG_{n+2}^m \) is an infinitely generated subgroup of \( G_n^m/G_{n+2}^m \).

We also prove that the abelianization of \( BG_n^m/BG_{n+1}^m \) has non-zero rank for \( n \geq 2 \) and \( m \geq 2 \) in Proposition 6.14. We conjecture these quotients groups are in fact infinitely generated.

To prove Theorem 6.8 we first show that \( \rho_n \) is additive when restricted to \( \mathcal{B}(m) \), the subgroup of \( \mathcal{C}(m) \) consisting of \( m \) component boundary string links. We note that \( \rho_n \) is not additive on \( \mathcal{C}(m) \) itself.

**Proposition 6.7.** For each \( n \geq 0 \) and \( m \geq 1 \), \( \rho_n : \mathcal{B}(m) \rightarrow \mathbb{R} \) is a homomorphism.

Next, we show that \((n + 1)\)-solvable links have vanishing \( \rho_n \). Thus, for each \( n \geq 0 \), \( \rho_n \) is a homomorphism from \( BF_n(\mathcal{C})/BF_{n+1}(\mathcal{C}) \) to \( \mathbb{R} \).
Theorem 6.4. If a 3-manifold $M$ is $(n)$-solvable then for each $(n)$-solution $W$ and $k \leq n$, the inclusion $i : M \to W$ induces monomorphisms

(1) \[ i_* : H_1(M; \mathcal{K}(\pi_1(W)/\pi_1(W)^{(k)})) \to H_1(W; \mathcal{K}(\pi_1(W)/\pi_1(W)^{(k)})) \]

and

(2) \[ i_* : \frac{\pi_1(M)}{\pi_1(M)^{(k+1)}} \to \frac{\pi_1(W)}{\pi_1(W)^{(k+1)}}; \]

and

(3) \[ \rho_{k-1}(M) = 0. \]

Thus, if $L \in \mathcal{F}(n)$ then $\rho_{k-1}(L) = 0$ for $k \leq n$.

To complete the proof of Theorem 6.8 we construct a collection of links that are $(n)$-solvable and have independent $\rho_n$. To do this we perform genetic infection on the $m$-component trivial link using some knot $K$ along some carefully chosen curve $\eta$ in $F^{(n)}$ where $F$ is the fundamental group of the trivial link. This produces a collection of boundary links $\{L(\eta, K)\}$ that are $(n)$-solvable and such that the image of $\rho_n$ restricted to $\{L(\eta, K)\}$ is infinitely generated.

We remark that the invariant $\rho_n$ is related to certain “finite” concordance invariants of boundary links associated to $p$-groups. Suppose $L$ is a boundary link with $m$ components. Then there is a surjective map $\pi : G \to F$ where $G = \pi_1(M_L)$ and $F$ is the free group on $m$ generators. By Theorem 4.1 of [6] (respectively Stallings’ Theorem [31]), $G/G_n^{(n)} \cong F/F_n^{(n)}$ (respectively $G/G_n \cong F/F_n$). Moreover, $M_L$ is the boundary of a 4-dimensional manifold $W$ over $F$. Since $F/F_n$ are residually finite $p$-groups, by work of W. Lück and T. Schick, both $\rho_n$ and $\rho_1^{\text{ext}}$ can be approximated by signatures of finite covers of $W$ where the covering groups are $p$-groups. These finite $p$-group signatures are closely related to the concordance invariants of boundary links studied by S. Friedl [18] and J. C. Cha and K. H. Ko [2].

We finish this paper by mentioning some applications to boundary link concordance in Section 7. In particular, we show $\rho_k$ gives a homomorphism from certain gamma groups (modulo automorphisms of the free group) to $\mathbb{R}$, generalizing work of Cappell and Shaneson. Here, $\mathcal{B}(n, m)$ is the group of concordance classes of $m$ component, $n$-dimensional boundary disk links in $D^{n+2}$.

Proposition 7.3. For each $n \equiv 1 \mod 4$ with $n > 1$, and each $k \geq 0$, there is an induced homomorphism

\[ \hat{\rho}_k : \overline{\Gamma}_{n+3}(ZF \to \mathbb{Z})/\text{Aut } F \to \mathbb{R} \]

that factors through $\mathcal{B}(n, m)$.

2. The Torsion-Free Derived Series

To define $\rho_n$, we must first introduce a new characteristic series of a group called the torsion-free derived series. In this section, we will define the torsion-free derived series and establish some its basic properties.

If $G$ is a group then $G/G_1^{(1)}$ is an abelian group but may have $\mathbb{Z}$-torsion. If one would like to avoid $\mathbb{Z}$-torsion then, in direct analogy to the rational lower-central series, one can define $G_1^{(1)} = \{x \in G \mid x^k \in [G, G] \text{ for some } k \neq 0\}$, which is slightly
larger than $G^{(1)}$, so that $G/G^{(1)}$ is $\mathbb{Z}$-torsion-free. Proceeding in this way, defining $G^{(n)}$ to be the radical of $[G^{(n-1)}, G^{(n-1)}]$, leads to what has been called the rational derived series of $G$ \cite{10, 8, 13}. This is the most rapidly descending series for which the quotients of successive terms are $\mathbb{Z}$-torsion-free abelian groups. Note that if $N$ is a normal subgroup of $G$ then $N/[N, N]$ is not only an abelian group but it is also a right module over $\mathbb{Z}[G/N]$, where the action is induced from conjugation in $G$ ($[x]g = [g^{-1}xg]$). To define the torsion-free derived series, we seek to eliminate torsion “in the module sense” from the successive quotients. We define the torsion-free derived series $G^{(n)}_H$ of $G$ as follows. First, set $G^{(0)} = G$. For $n \geq 0$, suppose inductively that $G^{(n)}_H$ has been defined and is normal in $G$ (we will show that $G^{(n)}_H$ is normal in $G$ below). Let $T_n$ be the subgroup of $G^{(n)}_H / [G^{(n)}_H, G^{(n)}_H]$ consisting of $\mathbb{Z}[G/G^{(n)}_H]$-torsion elements, i.e. the elements $[x]$ for which there exists some non-zero $\gamma \in \mathbb{Z}[G/G^{(n)}_H]$, such that $[x] \gamma = 0$. (In fact, since it will be (inductively) shown below that $\mathbb{Z}[G/G^{(n)}_H]$ is an Ore Domain, $T_n$ is a submodule). Now consider the epimorphism of groups:

$$G^{(n)}_H \xrightarrow{\pi_n} \frac{G^{(n)}_H}{[G^{(n)}_H, G^{(n)}_H]}$$

and define $G^{(n+1)}_H$ to be the inverse image of $T_n$ under $\pi_n$. Then $G^{(n+1)}_H$ is, by definition, a normal subgroup of $G^{(n)}_H$ that contains $[G^{(n)}_H, G^{(n)}_H]$. It follows inductively that $G^{(n)}_H$ contains $G^{(n+1)}_H$ (and $G^{(n+1)}_H$). Moreover, since $G^{(n)}_H / [G^{(n)}_H, G^{(n)}_H]$ is the quotient of the module $G^{(n)}_H / [G^{(n)}_H, G^{(n)}_H]$ by its torsion submodule, it is a $\mathbb{Z}[G/G^{(n)}_H]$ torsion-free module \cite{32} Lemma 3.4. Hence the successive quotients of the torsion-free derived subgroups are torsion-free modules over the appropriate rings. We define $G^{(\omega)}_H = \bigcap_{n<\omega} G^{(n)}_H$ as usual.

We now establish some elementary properties of the torsion-free derived series of a group. Recall that a group is poly-(torsion-free abelian) (often abbreviated PFTA) if it has a finite subnormal series whose successive quotients are torsion-free abelian groups. Such a group is solvable, torsion free, and locally indicable \cite{33} Proposition 1.9. If $G$ is PFTA then $\mathbb{Z}G$ is an Ore domain and hence admits a classical (right) ring of quotients $KG$, into which $\mathbb{Z}G$ embeds \cite{24}, pp. 591–592]. Hence any finitely generated (right) module $M$ over $\mathbb{Z}[G/G^{(n)}_H]$ has a well-defined rank that is defined to be the rank of the vector space $M \otimes \mathbb{Z}[G/G^{(n)}_H]. \mathcal{K}(G^{(n)}_H)$ \cite{12}, p. 48]. Alternatively the rank can be defined to be the maximal integer $m$ such that $M$ contains a submodule isomorphic to $(\mathbb{Z}[G/G^{(n)}_H])^m$.

**Proposition 2.1.** For each $0 \leq n < \omega$, $G^{(n)}_H$ is a normal subgroup of $G$ and $G/G^{(n)}_H$ is a poly-(torsion-free abelian) group. Consequently, $\mathbb{Z}[G/G^{(n)}_H]$ is an Ore domain.

**Proof.** We prove this by induction on $n$. The statement is clear for $n = 0$. Assume $G^{(n)}_H$ is a normal subgroup of $G$ and $G/G^{(n)}_H$ is PFTA. Let $x \in G^{(n+1)}_H$ and $g \in G$. Then $x$ and $g^{-1}xg$ lie in $G^{(n)}_H$ by assumption. By definition of the right module structure on $G^{(n)}_H / [G^{(n)}_H, G^{(n)}_H]$, $\pi_n(g^{-1}xg) = \pi_n(x)g$. Since $x \in G^{(n+1)}_H$, $\pi_n(x)$ is torsion. To show that $g^{-1}xg \in G^{(n+1)}_H$, it suffices to show that $\pi_n(x)g$ is torsion. Recall that the set of torsion elements of any module over an Ore domain is known to be a submodule \cite{32}, p. 57]. Since $\mathbb{Z}[G/G^{(n)}_H]$ is an Ore domain, it follows that the set of torsion elements in $G^{(n)}_H / [G^{(n)}_H, G^{(n)}_H]$ is a submodule. Thus, $\pi_n(x)g$ is torsion and hence $G^{(n+1)}_H$ is normal in $G$. 

Consider the normal series for $G/G^{(n+1)}_H$:
\[ 1 = \frac{G^{(n+1)}_H}{G^*_H} \supset \frac{G^{(n)}_H}{G^*_H} \supset \cdots \supset \frac{G^{(1)}_H}{G^*_H} \supset \frac{G}{G^*_H}. \]
Since the successive quotients of the above series are torsion-free abelian groups, $G/G^{(n+1)}_H$ is PTFA.

For convenience, we will often write $G/G^{(n)}_H$ as $G_n$ for any group $G$ (not to be confused with the terms of the lower central series of $G$ which we will denote by $G^n_{lc}$ in this paper).

We remark that the torsion-free derived subgroups are characteristic subgroups but they are not totally invariant. That is, an arbitrary homomorphism $\phi: A \to B$ need not send $A^{(n)}_H$ to $B^{(n)}_H$. To see this, let $A = \langle x, y, z | [z, [x, y]] \rangle$, $B = \langle x, y \rangle$ and $\phi: A \to B$ be defined by $\phi(x) = x$, $\phi(y) = y$ and $\phi(z) = 1$. Then $[x, y] \in A^{(n)}_H$ since $[x, y]$ is $(z_* - 1)$-torsion in $A^{(n)}_H/[A^{(n)}_H, A^{(n)}_H]$ where $z_* = [z] \in A/A^{(n)}_H$ but $\phi([x, y]) = [x, y] \not\in B^{(2)} = B^{(2)}_H$ (see Proposition 2.3).

**Proposition 2.2.** If $\phi: A \to B$ induces a monomorphism $\phi: A/A^{(n)}_H \to B/B^{(n)}_H$, then $\phi(A^{(n+2)}_H) \subset B^{(n+1)}_H$ and hence $\phi$ induces a homomorphism $\phi: A/A^{(n+1)}_H \to B/B^{(n+1)}_H$.

**Proof.** Note that the hypothesis implies that $\phi$ induces a ring monomorphism $\tilde{\phi}: \mathbb{Z}(A/A^{(n)}_H) \to \mathbb{Z}(B/B^{(n)}_H)$. Suppose that $x \in A^{(n)}_H$. Consider the diagram below.

\[ \begin{array}{ccc}
A^{(n)}_H & \overset{\pi_A}{\longrightarrow} & A^{(n)}_H \\
\downarrow \phi & & \downarrow \tilde{\phi} \\
B^{(n)}_H & \overset{\pi_B}{\longrightarrow} & B^{(n)}_H
\end{array} \]

By definition, $\pi_A(x)$ is torsion. That is, there is some non-zero $\gamma \in \mathbb{Z}[A/A^{(n)}_H]$ such that $\pi_A(x)\gamma = 0$. It is easy to check that $\tilde{\phi}$ is a homomorphism of right $\mathbb{Z}[A/A^{(n)}_H]$-modules using the module structure induced on $B^{(n)}_H/B^{(n+1)}_H$ by $\phi$ (since $\phi(a^{-1}xa) = \phi(a)^{-1}\phi(x)\phi(a)$). Thus $\tilde{\phi}(\pi_A(x))\tilde{\phi}(\gamma) = 0$. Since $\tilde{\phi}$ is injective, $\tilde{\phi}(\pi_A(x))$ is a $\mathbb{Z}[B/B^{(n)}_H]$-torsion element. But $\tilde{\phi}(\pi_A(x)) = \pi_B(\phi(x))$, showing that $\phi(x) \in B^{(n+1)}_H$. Hence $\phi(B^{(n+1)}_H) \subset B^{(n+1)}_H$.

For some groups, such as free groups and free-solvable groups $F/F^{(n)}$, the derived series and the torsion-free derived series coincide.

**Proposition 2.3.** If $G$ is a group such that, for each $n$, $G^{(n)}/G^{(n+1)}$ is torsion-free as a $\mathbb{Z}[G/G^{(n)}]$-module, then the torsion-free derived series of $G$ agrees with the derived series of $G$. Hence for a free group $F$, $F^{(n)} = F^{(n)}$ for each $n$.

**Proof.** By definition, $G^{(0)}_H = G^{(0)} = G$. Suppose $G^{(n)}_H = G^{(n)}$. Then, under the hypotheses, $G^{(n)}/[G^{(n)}, G^{(n)}]$ is a torsion-free module and hence $G^{(n+1)}_H = \ker \pi_n = [G^{(n)}_H, G^{(n)}_H] = [G^{(n)}, G^{(n)}] = G^{(n+1)}$.

It is well known that $F^{(n)}/F^{(n+1)}$ is a $\mathbb{Z}[F/F^{(n)}]$-torsion-free module. This can be seen by examining the free $\mathbb{Z}[F/F^{(n)}]$ cellular chain complex for the covering space.
of a wedge of circles corresponding to the subgroup \( F^{(n)} \). The module \( F^{(n)}/F^{(n+1)} \)
is merely the first homology of this chain complex. Since the chain complex can be
chosen to have no 2-cells, its first homology is a submodule of a free module and
thus is torsion-free. Hence, by the first part of this proposition, the derived series
and the torsion-free derived series of a free group agree. \(\blacksquare\)

In [6], T. Cochran and the author prove a version of Stallings’ Theorem [31] for
the derived series. Specifically, it was there shown that if a map of finitely presented
groups \( \phi : A \to B \) is rationally 2-connected then it induces a monomorphism
\[
\phi_* : A/A_n^{(n)} \to B/B_n^{(n)}
\]
for all \( n \geq 0 \) [6] Theorem 4.1] (see Theorem 2.4 and Proposition 2.5 below). For
this paper, we will need the following “generalization” of that theorem. The following
theorem is in fact a consequence of the proof of Theorem 4.1 of [6]. For
the convenience of the reader, we will sketch the proof of Theorem 2.4 after the
statement of Proposition 2.5.

**Theorem 2.4** (Scholium to Theorem 4.1 of [6]). Let \( n \) be a non-negative integer
or \( n = \infty \). If \( \phi : A \to B \) is a homomorphism that induces a monomorphism \( \phi_* : H_1(A;\mathbb{K}(B/B_n^{(k)})) \to H_1(B;\mathbb{K}(B/B_n^{(k)})) \) for each \( k \leq n \), then for each \( k \leq n \), \( \phi \) induces a monomorphism \( A/A_n^{(k+1)} \to B/B_n^{(k+1)} \). Moreover, if \( \phi : A \to B \) induces an isomorphism \( \phi_* : H_1(A;\mathbb{K}(B/B_n^{(k)})) \to H_1(B;\mathbb{K}(B/B_n^{(k)})) \) for each \( k \leq n \), then for each \( k \leq n \), \( \phi \) induces a monomorphism \( A_n^{(k)}/A_n^{(k+1)} \to B/B_n^{(k+1)} \) between modules of the same rank (over \( \mathbb{Z}[A/A_n^{(k)}] \) and \( \mathbb{Z}[B/B_n^{(k)}] \) respectively). In addition, if \( \phi \) is onto then \( \phi_* : A/A_n^{(k+1)} \to B/B_n^{(k+1)} \) is an isomorphism.

The following proposition guarantees that one of the hypotheses of Theorem 2.4
is satisfied whenever \( \phi \) is a rationally 2-connected map. Note that Proposition 2.5
and Theorem 2.4 together imply Theorem 4.1 of [6]. The justification for calling
Theorem 2.4 a generalization of Theorem 4.1 of [6], is that, in the subsequent
sections we will describe several conditions (see Proposition 3.15, Theorem 5.8,
Proposition 6.3, Proposition 6.6 and Lemma 6.5) under which the hypothesis of Theorem
2.4 is satisfied but where the 2-connected hypothesis of Theorem 4.1 of [6]
(and Proposition 2.5 and Proposition 4.3 of [6]) fails.

**Proposition 2.5** (Proposition 4.3 of [6]). Let \( A \) be a finitely-generated group and
\( B \) a finitely related group. Suppose \( \phi : A \to B \) induces a monomorphism (resp.
epimorphism) on \( H_1(\cdot;\mathbb{Q}) \) and an epimorphism on \( H_2(\cdot;\mathbb{Q}) \). Then for each \( k \geq 0 \), \( \phi \) induces a monomorphism (resp. epimorphism) \( \phi_* : H_1(A;\mathbb{K}(B/B_n^{(k)})) \to H_1(B;\mathbb{K}(B/B_n^{(k)})) \).

**Proof of Theorem 2.4**. We sketch the inductive proof of the first claim of the theorem,
referring the reader to [6] for more details. For \( n = 0 \), \( A/A_0^{(0)} \) is merely
\( H_1(A;\mathbb{Z})/\{\mathbb{Z}\text{-Torsion}\} \). But \( A/A_0^{(0)} = \{e\} \) so \( \mathbb{K}(A/A_0^{(0)}) = \mathbb{Q} \). Thus our hypothesis,
that \( \phi \) induces a monomorphism on \( H_1(\cdot;\mathbb{Q}) \), implies that \( \phi \) induces a monomorphism
on \( H_1(\cdot;\mathbb{Z}) \) modulo torsion. Now assume that \( \phi \) induces a monomorphism
\( A/A_n^{(n)} \subset B/B_n^{(n)} \). We will prove that this holds for \( n + 1 \).

It follows from Proposition 2.2 that \( \phi(A_n^{(n+1)}) \subset B_n^{(n+1)} \). Thus from the commutative diagram below we see that it suffices to show that \( \phi \) induces a monomorphism
The torsion submodule is characterized precisely as the kernel of the canonical map $L$ of the fundamental group of the manifold. We begin by recalling the definition of the $n$-signature defect associated to the torsion class $[a]$ in $A^{(n)}/[A^{(n)}, A^{(n)}]$ such that $\phi(a)$ represents a non-torsion class $A^{(n)}$. Now suppose that $A^{(n)}/[A^{(n)}, A^{(n)}] \rightarrow B^{(n)}/[B^{(n)}, B^{(n)}]$ were not injective. From our discussions above in the proof of Proposition 2.2 we see that there would exist an $a \in A^{(n)}$ representing a non-torsion class $A^{(n)}$ such that $\phi(a)$ represents a torsion class in $B^{(n)}/[B^{(n)}, B^{(n)}]$. But

\[
A^{(n)}/[A^{(n)}, A^{(n)}] \cong H_1(A; \mathbb{Z}[A^{(n)!}]).
\]

The torsion submodule is characterized precisely as the kernel of the canonical map $H_1(A; \mathbb{Z}[A^{(n)!}]) \rightarrow H_1(A; \mathbb{Z}[A^{(n)!}]) \otimes_{\mathbb{Z}[A^{(n)!}]} K(A^{(n)!}) \cong H_1(A; K(A^{(n)!})�).

A similar statement holds for $B$. But the inductive hypothesis that $A/A^{(n)} \subset B/B^{(n)}$ guarantees that $H_1(A; K(A^{(n)!})) \rightarrow H_1(A; K(B/B^{(n)!}))$ is injective. Moreover, the hypothesis of the theorem guarantees that $H_1(A; K(B/B^{(n)!})) \rightarrow H_1(B; K(B/B^{(n)!}))$ is injective, leading to a contradiction. \hfill \square

3. Definition of $\rho_n$

On the class of closed, oriented $(4k - 1)$-dimensional manifolds, we will define a $\mathbb{Q}$-homology cobordism invariant $\rho_n$ for each $n \in \mathbb{N}$. This will be defined as a signature defect associated to the $n$th term of the torsion-free derived series of the fundamental group of the manifold. We begin by recalling the definition of the $L^2$-signature of a 4k-dimensional manifold. For more information on $L^2$-signature and $\rho$-invariants see [13, Section 2], [11, Section 5] and [26].

Let $\Lambda$ be a countable group and $\mathcal{U} \Lambda$ be the algebra of unbounded operators affiliated to $\mathcal{N} \Lambda$, the von Neumann algebra of $\Lambda$. Then $\sigma^{(2)}_\Lambda : \text{Herm}_n(\mathcal{U} \Lambda) \rightarrow \mathbb{R}$ is defined by

\[
\sigma^{(2)}_\Lambda(h) = \text{tr}_\Lambda(p_+(h)) - \text{tr}_\Lambda(p_-(h))
\]

for any $h \in \text{Herm}_n(\mathcal{U} \Lambda)$ where $\text{tr}_\Lambda$ is the von Neumann trace and $p_\pm$ are the characteristic functions on the positive and negative reals. It is known that $\sigma^{(2)}_\Lambda$ can be extended to the Witt group of Hermitian forms on finitely generated projective $\mathcal{U} \Lambda$-modules.

**Lemma 3.1** (see for example Corollary 5.7 of [11] and surrounding discussion). The $L^2$-signature, $\sigma^{(2)}$, is a well-defined real-valued homomorphism on the Witt group of hermitian forms on finitely generated projective $\mathcal{U} \Lambda$-modules. Restricting this homomorphism to nonsingular forms on free modules gives

\[
\sigma^{(2)}_\Lambda : L^0(\mathcal{U} \Lambda) \rightarrow \mathbb{R}.
\]
In particular, if $h$ is a nonsingular pairing with a metabolizer then $\sigma^{(2)}_h(h) = 0$.

Let $W$ be a $4k$-dimensional manifold and $\Phi : \pi_1(W) \to \Lambda$ be a coefficient system for $W$. Let $h_{W,\Lambda}$ be the composition of the following homomorphisms

$$H_{2k}(W; U\Lambda) \to H_{2k}(W,\partial W; U\Lambda) \xrightarrow{PD} H^{2k}(W; U\Lambda) \xrightarrow{\cup} H_{2k}(W; U\Lambda)^*$$

where $H_{2k}(W; U\Lambda)^* = \text{Hom}_{U\Lambda}(H_{2k}(W; U\Lambda), U\Lambda)$. Since $U\Lambda$ is a von Neumann regular ring, the modules $H_{2k}(W; U\Lambda)$ are finitely generated projective right $U\Lambda$-modules. Then $h_{W,\Lambda} \in \text{Herm}_n(U\Lambda)$ and we define $\sigma^{(2)}(W,\Lambda) = \sigma^{(2)}_h(h_{W,\Lambda})$. We will sometimes write $\sigma^{(2)}(W,\Lambda)$ as $\sigma^{(2)}_h(W)$ or $\sigma^{(2)}(W,\Phi)$ when we want to emphasize the map $\Phi$.

Suppose that $\Lambda$ is PTFA. Let $U$ be a (possibly empty) union of components of the boundary of $W$. Then $\mathbb{Z}\Lambda$ embeds in its right ring of quotients $\mathcal{K}\Lambda$. Moreover, the map from $\mathbb{Z}\Lambda$ to $U\Lambda$ factors as $\mathbb{Z}\Lambda \to \mathcal{K}\Lambda \to U\Lambda$ making $U\Lambda$ into a $\mathcal{K}\Lambda - U\Lambda$-bimodule. Since any module over a skew field is free, $U\Lambda$ is a flat $\mathcal{K}\Lambda$-module. Hence, $H_{2k}(W, U; U\Lambda) \cong H_2(W, U; \mathcal{K}\Lambda) \otimes_{\mathcal{K}\Lambda} U\Lambda$. In particular, $H_{2k}(W, U; \mathcal{K}\Lambda) = 0$ if and only if $H_2(W, U; U\Lambda) = 0$.

We will use the following facts about $L^2$-signatures throughout this paper. The first two remarks follow directly from the definition of $\sigma^{(2)}(W,\Lambda)$.

**Remark 3.2.** Suppose $W$ is a compact, oriented $4k$-dimensional manifold and $\Psi : \pi_1(W') \to \Lambda$ is a coefficient system for $W$.

1. If $H_{2k}(W, U; U\Lambda) = 0$ (or $H_{2k}(W, U; \mathcal{K}\Lambda) = 0$ if $\Lambda$ is PTFA), where $U$ is a (possibly empty) union of components of the boundary of $W$, then $\sigma^{(2)}(W,\Lambda) = 0$.
2. If $\Lambda = \{1\}$ is the trivial group then $\sigma^{(2)}(W,\Lambda) = \sigma(W)$ where $\sigma$ is the ordinary signature function.
3. If $\Lambda \subset \Lambda'$ then $\sigma^{(2)}(W,\Lambda) = \sigma^{(2)}(W,\Lambda')$ (see for example, Proposition 5.13 of [11]).
4. Suppose $V$ is another compact, oriented $4k$-dimensional manifold, $\Psi' : \pi_1(V') \to \Lambda$ is a coefficient system for $V$ and $(V,\Psi')$ has the same oriented boundary as $(W,\Psi)$ (meaning the maps to $\Lambda$ agree on the boundary) then

$$\sigma^{(2)}(W \cup_{\partial W} V, \Psi \cup \Psi') = \sigma^{(2)}(W,\Psi) - \sigma^{(2)}(V,\Psi')$$

(see for example, Lemma 5.9 of [11]).
5. If $W$ is closed then $\sigma^{(2)}(W,\Lambda) = \sigma(W)$ (see for example, Lemma 5.9 of [11]).

We now define $\rho_r(M)$ for a $(4k-1)$-dimensional manifold and coefficient system $\pi_1(M) \to \Gamma$. Let $M$ be a closed, orientable, $l$-dimensional manifold with $l \neq 0 \mod 4$. It is well known that $rM$ is the boundary of some compact, orientable manifold for $r \in \{1, 2\}$. J.-C. Hausmann showed further [21] Theorem 5.1 that $rM$ is the boundary of a compact, orientable manifold $W$ for which the inclusion map of $M$ into $W$ induces a monomorphism on $\pi_1$. That is, $rM$ is stably nullbordant over $\pi_1(M)$ for some $r \in \{1, 2\}$ in the language of Definition 5.3 below. In [21], S. Chang and S. Weinberger use this fact to define a new “Hirzebruch type” invariant $\tau^{(2)}_r$ for a $(4k-1)$-dimensional manifold $M$ by setting $\tau^{(2)}_r(M) = \frac{1}{2}(\sigma^{(2)}(W,\pi_1(W)) - \sigma(W))$. To define $\rho_r$ we proceed in a similar manner, stably bounding over $\pi_1(M)_r$ instead of $\pi_1(M)$. To do this, we will show that $rM$ is stably nullbordant over $\Gamma$ for any coefficient system $\pi_1(M) \to \Gamma$. 

**Definition 3.3.** Let $M = M_1 \cup \cdots \cup M_m$ be a disjoint union of $m$ connected, closed, oriented $l$-dimensional manifolds and $S = \{ \phi_i : \pi_1(M_i) \to \Gamma_i \}_{i=1}^m$ be a collection of coefficient systems for $M$. We say that $(M, S)$ is **stably nullbordant** (or **s-nullbordant**) if there exists a triple $(W, \Phi, T)$ where $W$ is a compact, connected, oriented $(l+1)$-dimensional manifold with $\partial W = M$, $\Phi : \pi_1(W) \to \Lambda$ is a coefficient system for $W$, and $T = \{ \theta_i : \Gamma_i \to \Lambda_1 \}_{i=1}^m$ is a collection of monomorphisms such that for each $1 \leq i \leq m$, the following diagram commutes (after modifying $\Phi$ by a change of basepoint isomorphism)

\[
\begin{array}{cccc}
\pi_1(M_i) & \phi_i & \Gamma_i \\
\downarrow (\iota_i)_* & & \downarrow \theta_i \\
\pi_1(W) & \Phi & \Lambda
\end{array}
\]

where $\iota_i : M_i \to W$ is the inclusion map. We call the triple $(W, \Phi, T)$ a **stable (or s-)nullbordism** for $(M, S)$. We say that $(M_1, S_1)$ is **stably (or s-)bordant** to $(M_2, S_2)$ if $(M_1 \cup M_2, S_1 \cup S_2)$ is s-nullbordant. If, in addition, $\Gamma_i \cong \Gamma$ for each $i = 1, \ldots, m$, we say that $M$ is **stably (or s-)nullbordant over** $\Gamma$ or that $(M, \Gamma)$ is **stably (or s-)nullbordant**.

We remark that stable bordism is an equivalence relation since if $(W_1, \Phi_1 : \pi_1(W_1) \to \Lambda_1, \{ \phi_i', \phi_i'' \})$ is an s-nullbordism for $(M_i \cup M_{i+1}, \{ \phi_i, \phi_{i+1} \})$ ($i = 1, 2$) then $(W = W_1 \cup_{M_2} W_2, \Phi : \pi_1(W) \to \Lambda_1 *_{\Gamma_2} \Lambda_2, \{ \theta_i', \theta_i'' \})$ is an s-nullbordism for $(M_1 \cup M_3, \{ \phi_1, \phi_3 \})$ when $\Phi = \Phi_1 * \Phi_2$, and $\theta_i', \theta_i''$ are the obvious compositions.

The proof of the following lemma is similar to the proof of Hausmann’s Theorem 5.1. [22].

**Lemma 3.4.** Let $M = M_1 \cup \cdots \cup M_m$ be a disjoint union of closed, connected, oriented $l$-dimensional manifolds and $S = \{ \phi_i : \pi_1(M_i) \to \Gamma_i \}_{i=1}^m$ be a collection of coefficient systems. If $M$ is nullbordant then $(M, S)$ is s-nullbordant.

**Proof.** If $\Gamma = \Gamma_1 * \cdots * \Gamma_m$ is the free product of the collection $\{ \Gamma_i \}$ then there is a natural inclusion $\Gamma_i \hookrightarrow \Gamma$ for each $i$. By the homological coning construction of $\Lambda$, Thurston-W. Kan, $\Gamma$ is subgroup of an acyclic group $\Lambda_\Gamma$ [22, Section 3]. For each $i$, let $\theta_i : \Gamma_i \hookrightarrow \Lambda_\Gamma$ be the inclusion of $\Gamma_i$ into the acyclic group $\Lambda_\Gamma$. The collection $\{ \theta_i \circ \phi_i \}$ gives us a map $f : M \to K(\Lambda_\Gamma, 1)$ such that $(f|_{M_i})_* = \theta_i \circ \phi_i$ for each $i$ and the following diagram commutes.

\[
\begin{array}{ccc}
M & \xrightarrow{f} & K(\Lambda_\Gamma, 1) \\
\downarrow \iota & & \\
W & \xrightarrow{pt} \\
\end{array}
\]

Since $K(\Lambda_\Gamma, 1)$ is acyclic, the map $K(\Lambda_\Gamma, 1) \to pt$ induces an isomorphism on integral homology, hence an isomorphism on oriented bordism theory. Since $M = \partial W$, this implies that there is a compact manifold $W'$ and map $g : W' \to K(\Lambda_\Gamma, 1)$ such that $g|_{\partial W'} = f$. Hence $(W', g, \{ \theta_i \})$ is an s-nullbordism for $M$. \qed
Since the $l$-dimensional oriented bordism group $Ω^\text{or}_l(pt)$ is 2-torsion when $l \neq 0 \mod 4$, there is always an $(l + 1)$-dimensional manifold $W$ such that $\partial W = 2M$. Hence we see that $(2M, \{\phi\})$ is always s-nullbordant.

**Corollary 3.5.** If $M$ is a closed, connected, oriented $l$-dimensional manifold with $l \neq 0 \mod 4$ and $\phi : \pi_1(M) \to \Gamma$ is a coefficient system for $M$ then there is an integer $r \in \{1, 2\}$ such $rM$ is s-nullbordant over $\Gamma$.

In this paper, we will often assume that $M$ is a 3-dimensional manifold. Since every closed, oriented 3-dimensional manifold is the boundary of a compact, oriented 4-dimensional manifold, $(M, \phi)$ is s-nullbordant for any $\phi : \pi_1(M) \to \Gamma$.

For a $(4k - 1)$-dimensional closed, oriented manifold $M$ and homomorphism $\phi : \pi_1(M) \to \Gamma$, we define

$$\rho(M, \phi) := \frac{1}{r}(\sigma^2(W, \Lambda) - \sigma(W))$$

for $(W, \Psi)$ any s-nullbordism for $(rM, \phi)$ where $\sigma(W)$ is the ordinary signature of $W$. By the following Lemma, this definition only depends on $M$ and $\phi$.

**Lemma 3.6.** $\rho(M, \phi)$ is independent of the choice of $(W, \Phi, \theta)$.

**Proof.** Let $(W, \Phi, \mathcal{T})$ and $(W', \Phi', \mathcal{T}')$ be two s-nullbordisms for $(rM, \{\phi\})$ and $(rM, \{\phi\})$ respectively. Assume that $r_1 = r_2 = 1$. Let $C = W \cup W'$ be the closed, oriented 4k-manifold obtained by gluing $W$ and $W'$ along $M$. Then there is a coefficient system for $C$,

$$\Phi * \Phi' : \pi_1(C) = \pi_1(W) *_{\pi_1(M)} \pi_1(W') \to \Lambda *_{\pi_1(M)} \Lambda' = \Lambda *_{\Gamma} \Lambda'$$

such that $\Phi * \Phi'(\alpha) = i_{\Lambda}(\Phi(\alpha))$ for all $\alpha \in \pi_1(W)$ where $i_{\Lambda} : \Lambda \to \Lambda *_{\Gamma} \Lambda'$ sends $\lambda \in \Lambda$ to the word $\lambda \in \Lambda *_{\Gamma} \Lambda'$ (similarly for $\alpha \in \pi_1(W')$). Since $\theta : \Gamma \to \Lambda$ and $\theta' : \Gamma \to \Lambda'$ are monomorphisms, the maps $i_{\Lambda}$ and $i_{\Lambda'}$ are monomorphisms. Hence by Remark 3.3, $\sigma^2(W, \Lambda) = \sigma^2(W, \Lambda *_{\Gamma} \Lambda')$ and $\sigma^2(W', \Lambda') = \sigma^2(W', \Lambda *_{\Gamma} \Lambda')$. Moreover, by Remark 3.3 (4)

$$\sigma^2_{\Lambda *_{\Gamma} \Lambda'}(C) - \sigma(C) = (\sigma^2_{\Lambda *_{\Gamma} \Lambda'}(W') - \sigma(W)) - (\sigma^2_{\Lambda *_{\Gamma} \Lambda'}(W') - \sigma(W')).$$

Since $C$ is closed, by Remark 3.3 (5), the left hand side of (6) is 0. Therefore, $\sigma^2_{\Lambda} (W) - \sigma(W) = \sigma^2_{\Lambda'} (W') - \sigma(W')$. The proofs when $r_i \neq 1$ are similar and are not included since most of our applications focus on 3-manifolds where $r$ can be assumed to be 1.

Note that we may occasionally write $\rho(M, \phi)$ as $\rho_r(M)$ or $\rho(M, \Gamma)$ when the map $\phi$ is clear. As a result of Remark 3.3, $\rho_r(M)$ only depends on the image of $\pi_1(M)$ in $\Gamma$.

**Lemma 3.7** (Γ-induction). Suppose $M$ is a closed, oriented $(4k - 1)$-dimensional manifold and $\phi : \pi_1(M) \to \Gamma$ is a coefficient system for $M$. If $\iota : \Gamma \to \Gamma'$ is a monomorphism then $\rho(M, \phi) = \rho(M, \phi \circ \iota)$.

**Definition 3.8.** For each $0 \leq n \leq \omega$ and $(4k - 1)$-dimensional closed, oriented manifold $M$, we define the $n^{th}$-order $\rho$-invariant of $M$ by

$$\rho_n(M) := \rho(M, \phi_n : G \to G / G^{(n+1)}_H) \in \mathbb{R}$$

where $G = \pi_1(M)$. 

We will now define the $n^{\text{th}}$-order $\rho$-invariant of a link in $S^3$. First, suppose $L \subset S^3$ is an $m$-component link in $S^3$ with linking numbers 0. Let $N(L)$ be a neighborhood of $L$ in $S^3$.

**Proposition 3.9.** Let $L \subset S^3$ be a link for which all the pairwise linking numbers are zero and $G = \pi_1(S^3 - N(L))$. The longitudes of $L$ lie in $G^{(n)}_H$.

**Proof.** Let $\lambda_i$ be the longitude of the $i^{\text{th}}$ component of $L$. We will show that for each $n \geq 1$, $\lambda_i \in G^{(n)}_H$. Since the linking numbers of $L$ are zero, $\lambda_i \in G^{(1)}_H$. Suppose that $\lambda_i \in G^{(n)}_H$, for some $n \geq 1$. Since the longitudes lie on the boundary tori, they commute with the meridians $x_i$. Hence for each $i$, $[x_i, \lambda_i] = 1$ is a relation in $G$. The relation $[x_i, \lambda_i] = 1$ in $G$ creates the relation $\lambda_i(1 - x_i) = 0$ in the module $G^{(n)}_H/[G^{(n)}_H, G^{(n)}_H]$, showing that $\lambda_i \in G^{(n+1)}_H$ since $x_i \neq 1$ in $G/G^{(n)}_H$. □

By contrast, the longitudes rarely lie in $G_\omega$, much less in $G^{(\omega)}_H$, the former being true if and only if all of Milnor’s $\tau$-invariants are zero. The Borromean Rings and the Whitehead links provide examples where the longitudes lie in $G^{(\omega)}_H$ but not in $G_\omega$.

As a corollary, performing 0-framed surgery on a link with linking numbers 0 does not change the quotient of the link group by a term its torsion-free derived series.

**Corollary 3.10** (see Proposition 2.5 of [6]). Suppose $L \subset S^3$ is a link with linking numbers 0. Let $M_L$ be the closed 3-manifold obtained by performing 0-framed surgery on the components of $L$ and $i : S^3 - N(L) \to M_L$ be the inclusion map. Then for each $n \geq 1$,

$$\frac{\pi_1(S^3 - N(L))}{\pi_1(S^3 - N(L))^{(n)}_H} \cong \frac{\pi_1(M_L)}{\pi_1(M_L)^{(n)}_H}$$

**Proof.** The kernel of $i_*$ is the normal subgroup generated by the longitudes. But by Proposition 3.9 above, the longitudes lie in $\pi_1(S^3 - N(L))^{(n)}_H$ for all $n \geq 0$. □

Hence it makes sense to make the following definition of $\rho_n$ for a link. Note that the following definition does not require that the linking numbers be 0.

**Definition 3.11.** Let $L$ be a link in $S^3$. For each $0 \leq n \leq \omega$ we define

$$\rho_n(L) = \rho\left(M_L, \phi_n : \pi_1(M_L) \to \frac{\pi_1(M_L)}{\pi_1(M_L)^{(n+1)}_H}\right).$$

As an easy example, we show that $\rho_n(\#_{i=1}^m S^1 \times S^2) = \rho_n(\text{trivial link}) = 0$ for all $0 \leq n \leq \omega$.

**Example 3.12.** Let $W$ be the boundary connected sum of $m$ copies of $S^1 \times D^3$. Then $\partial W = \#_{i=1}^m S^1 \times S^2$. Moreover, the inclusion $i : \partial W \to W$ induces an isomorphism on $\pi_1$. Let $\Gamma_n = F/F_\sigma^{(n+1)}$ where $F = \pi_1(W)$ is the free group with $m$ generators. By definition, $\rho_n(\partial W) = \sigma^{(2)}_n(W) - \sigma(W)$. Since $W$ is homotopy equivalent to a 1-complex, $H_2(W; Z\Gamma_n) = 0$. Hence, $\sigma^{(2)}_n(W) = \sigma(W) = 0$. In particular, $\rho_n(\#_{i=1}^m S^1 \times S^2) = \rho_n(\text{trivial link}) = 0$.

The most important and easiest example to understand is $\rho_0$ for a knot in $S^3$. In this case, $\rho_0$ is determined by the Levine-Tristram signatures of the knot.
Example 3.13. Let $K$ be a knot in $S^3$. By Lemma 5.4 of [11] and Lemma 5.3 of [12],
\[ \rho_0(K) = \int_{S^1} \sigma_\omega(K) d\omega \]
where $\sigma_\omega(K)$ is the Levine-Tristram signature of $K$ at $\omega \in S^1$ and the circle is normalized to have length 1. Since $\beta_1(M_K) = 1$, the Alexander module of $M_K$ is torsion [11 Proposition 2.11]. Therefore, for $n \geq 0$, $\pi_1(M_K)^{(n+1)} = \pi_1(M_K)^{(1)}$; hence $\rho_n(K) = \rho_0(K)$.

A nice property of $\rho_n$ is that it is additive under the connected sum of manifolds. To prove this, we show that the torsion free derived series behaves well under the inclusion $A \to A \ast_c B$ for suitable $C$. We start with a lemma.

Lemma 3.14. Let $\phi : C \to G$ be a homomorphism. If $\beta_1(C) = 0$ then the image of $\phi$ is contained in $G^{(n)}_H$.

Proof. We will show by induction on $n$ that $\phi(C) \subset G^{(n)}_H$ for all $n \geq 0$. This is trivial when $n = 0$. Suppose for some $n \geq 0$, that $\phi(C) \subset G^{(n)}_H$. Then $\phi$ induces a map $\phi_* : C/[C,C] \to G^{(n)}_H/G^{(n)}_H$, $[G^{(n)}_H,G^{(n)}_H] \to G^{(n)}_H/G^{(n+1)}_H$. Since $\beta_1(C) = 1$, $C/[C,C]$ is $\mathbb{Z}$-torsion. However, $G^{(n)}_H/G^{(n+1)}_H$ is $\mathbb{Z}$-torsion free, hence $\phi_*$ is trivial which implies $\phi(C) \subset G^{(n+1)}_H$. \hfill \Box

Proposition 3.15. Let $A \ast_c B$ be the amalgamated product of $A$ and $B$ where $C \hookrightarrow A$ and $C \hookrightarrow B$ are monomorphisms and $\beta_1(C) = 0$. For each $0 \leq n \leq \omega$, the inclusion $i : A \to A \ast_c B$ induces a monomorphism
\[ i_* : A^{(n)}_H \to (A \ast_c B)^{(n)}_H. \]

Proof. Let $G = A \ast_c B$. For each $n \geq 0$, we have the following Mayer-Vietoris sequence for group homology with $KG_n$-coefficients
\[ H_1(C;KG_n) \to H_1(A;KG_n) \oplus H_1(B;KG_n) \to H_1(G;KG_n) \to H_0(C;KG_n), \]
where the coefficients systems for $A$, $B$, $C$ and $G$ are the obvious ones. By Lemma 3.14 the image of $C \to G \to G_n$ is trivial hence $H_1(C;ZG_n) \cong H_1(C;Z) \otimes ZG_n$.

Since $Q$ is a flat $\mathbb{Z}$-module, $KG_n$ is a flat $\mathbb{Z}G_n$-module, and $\beta_1(C) = 0$, it follows that $H_1(C;KG_n) \cong H_1(C;Q) \otimes_Q KG_n = 0$. Here, the map $Q \to KG_n$ is induced by $1 \to G_n$. Thus $i_* : H_1(A;KG_n) \to H_1(G;KG_n)$ is a monomorphism. By Theorem 2.4 $i$ induces a monomorphism $A/A^{(n)}_H \to G/G^{(n)}_H$ as desired. Since $A/A^{(n)}_H \to G/G^{(n)}_H$ for all $n \geq 0$, it follows immediately from the definition of $A^{(n)}_H$ and $G^{(n)}_H$ that $A/A^{(n)}_H \to G/G^{(n)}_H$. \hfill \Box

Proposition 3.16. Let $k \geq 1$ and let $M_1$ and $M_2$ be closed, oriented, connected $(4k-1)$-dimensional manifolds. For each $0 \leq n \leq \omega$,
\[ \rho_n(M_1 \# M_2) = \rho_n(M_1) + \rho_n(M_2). \]

Proof. Let $W$ be the $4k$-manifold obtained by adding a 1-handle to $(M_1 \sqcup M_2) \times I$ along some $D^{4k-1} \cup B^{4k-1} \subset (M_1 \sqcup M_2) \times \{1\}$ and $G = \pi_1(W)$. Then $\partial W = M_1 \cup M_2 \cup M_1 \# M_2$ so $\sigma^2(W,G_n) - \sigma(W) = \rho(M_1,G_n) + \rho(M_2,G_n) - \rho(M_1 \# M_2,G_n)$. Since the inclusion $i : M_1 \# M_2 \to W$ induces an isomorphism on $\pi_1$, by Lemma 3.7 $\rho_n(M_1 \# M_2) = \rho_n(M_1) + \rho_n(M_2)$. Moreover $G = \pi_1(M_1) \ast \pi_1(M_2)$ and the inclusion map $i_1 : M_1 \to W$ induces the inclusion map $(i_1)_* : \pi_1(M_1) \to \pi_1(M_1) \ast \pi_1(M_2) on
If \( M_1 \) and \( M_2 \) are oriented, closed \( m \)-dimensional manifolds. We say that \( M_1 \) is \( \mathbb{Q} \)-homology cobordant (respectively homology cobordant) to \( M_2 \) if there exists an oriented, \((m+1)\)-manifold \( W^{m+1} \) such that \( \partial W = M_1 \cup M_2 \), and the inclusion maps \( i_j : M_j \to W \) induce isomorphisms on \( H_* (\cdot ) \) (respectively \( H_* (\cdot ; \mathbb{Z}) \)). In this case we write \( M_1 \sim_{\mathbb{Q}H} M_2 \) (respectively \( M_1 \sim_{\mathbb{Z}H} M_2 \)) and define the set of rational (respectively integral) homology cobordism classes of \( m \)-dimensional manifolds to be \( \mathcal{C}^m_{\mathbb{Q}} = \{ M^m \} / \sim_{\mathbb{Q}H} \) (respectively \( \mathcal{C}^m_{\mathbb{Z}} = \{ M^m \} / \sim_{\mathbb{Z}H} \)).

We will show that \( \rho_n \) is an invariant of \( \mathbb{Q} \)-homology cobordism. Since two manifolds that are homology cobordant are necessarily rationally homology cobordant, \( \rho_n \) is an invariant of homology cobordism.

**Theorem 4.2.** If \( M_1^{k-1} \) is \( \mathbb{Q} \)-homology cobordant to \( M_2^{k-1} \) \((k \geq 1)\) then \( \rho_n (M_1) = \rho_n (M_2) \).

**Proof.** Let \( W \) be a \( 4k \)-dimensional manifold such that \( \partial W = M_1 \cup M_2 \), \( i_j : M_j \to W \) be the inclusion maps, \( E = \pi_1(W) \), and \( G_j = \pi_1(M_j) \) for \( j = 1, 2 \). Since \( (i_j)_*: H_k (M_j; \mathbb{Q}) \to H_k (W; \mathbb{Q}) \) is an isomorphism for \( k = 1, 2 \), \( (i_j)_*: H_k (G_j; \mathbb{Q}) \to H_k (E; \mathbb{Q}) \) is an isomorphism and \( (i_j)_* : H_2 (G_j; \mathbb{Q}) \to H_2 (E; \mathbb{Q}) \) is surjective. Hence by Theorem 4.1 of [6], for each \( n \geq 0 \), the inclusion maps induce monomorphisms

\[
(i_j)_*: \frac{G_j}{(G_j)_{H}^{(n+1)}} \to \frac{E}{E_H^{(n+1)}}.
\]

Let \( \Gamma_n = E/E_H^{(n+1)} \), then we have coefficient systems \( (\beta_j)_n : G_j \to \Gamma_n \) defined by \( (i_j)_* \circ (\phi_j)_n \) where \( (\phi_j)_n : G_j \to G_j/(G_j)_{H}^{(n+1)} \) is the quotient map. By Remark [3.2] [4], we have \( \rho_n (M_j) = \rho (M_j, G_j \to \Gamma_n) \). Therefore

\[
\rho_n (M_1) - \rho_n (M_2) = \rho (\partial W, \Gamma_n) = \sigma^{(2)} (W, \Gamma_n) = \sigma (W).
\]

To finish the proof, we show that \( \sigma^{(2)} (W, \Gamma_n) = \sigma (W) = 0 \). Since \( (i_1)_*: H_2 (M_1; \mathbb{Q}) \to H_2 (W; \mathbb{Q}) \) is surjective, the second homology of \( W \) comes from the boundary. Thus the intersection of any two classes is \( H_2 (W, \mathbb{Q}) \) is zero. In particular \( \sigma (W) = 0 \). Let \( \mathcal{K}_n \) be the classical right ring of quotients of \( \mathbb{Z} \). Since \( H_i (W, M_1; \mathbb{Q}) = 0 \) for \( i = 0, 1, 2 \) then by Proposition 2.10 of [11], \( H_i (W, M_1; \mathcal{K}_n) = 0 \) for \( i = 0, 1, 2 \). By Remark [3.2] [4], \( \sigma^{(2)} (W, \Gamma_n) = 0 \). \( \square \)
Hence, for each \( n \geq 0 \) and \( m = 4k - 1 \) with \( k \geq 1 \) we have a map
\[
\rho_n : \mathcal{H}_Q^m \to \mathbb{R}.
\]
Note that if \( L_1 \) and \( L_2 \) are concordant links then their 0-surgeries are homology cobordant hence \( \rho_n(L_1) = \rho_n(L_2) \). Moreover, \( \rho_n \) of the trivial link is 0 as in Example [3,12].

**Corollary 4.3.** For each \( n \geq 0 \), \( \rho_n \) is a concordance invariant of links and is 0 for slice links.

We will use \( \rho_n \) to further investigate the structure of concordance classes of links in Section [6].

### 5. Non-triviality of \( \rho_n \)

We will show that the \( \rho_n \) are highly non-trivial. To do this we will show that the image of \( \rho_n : \mathcal{H}_Q^3 \to \mathbb{R} \) in \( \mathbb{R} \) is dense and is an infinitely generated subset of \( \mathbb{R} \). Before we can do this, we must define a family of examples of 3-manifolds on which we can calculate \( \rho_n \).

#### 5.1. Examples: Genetic Modification.

We describe a procedure wherein one starts with a 3-manifold \( M \) (respectively a link \( L \) in \( S^3 \)) and “infects” \( M \) (respectively \( L \)) along a curve \( \eta \) in \( M \) (respectively \( S^3 - L \)) with a knot \( K \) in \( S^3 \) to obtain a new 3-manifold \( M(\eta, K) \) with the same homology as \( M \) (respectively link \( L(\eta, K) \) in \( S^3 \)). This construction is a specific type of satellite constructions which has been dubbed *genetic infection* (see Section 3 of [12]).

We first describe the construction for a general 3-manifold. Let \( M \) be a compact, connected, oriented 3-manifold, \( \eta \) be a curve embedded in \( M \), and \( K \) be a knot in \( S^3 \). Denote by \( N(\eta) \) and \( N(K) \) a tubular neighborhood of \( \eta \) in \( M \) and \( K \) in \( S^3 \) respectively. Let \( \mu_\eta \) and \( \mu_K \) be the meridians of \( \eta \) and \( K \) respectively, and let \( l_\eta \) and \( l_K \) be the longitudes of \( \eta \) and \( K \) respectively. Note that if \( \eta \) is not nullhomologous then the longitude of \( \eta \) is not well-defined. In this case, we choose \( l_\eta \) to be an embedded curve on \( N(\eta) \) that is isotopic to \( \eta \) in \( M \) and intersects \( \mu_\eta \) geometrically once. Define
\[
M(\eta, K) = (M - N(\eta)) \cup_f (S^3 - N(K))
\]
where \( f : \partial(S^3 - N(K)) \to \partial(M - N(K)) \) is defined by \( f_*(\mu_K) = l_\eta^{-1} \) and \( f_*(l_K) = \mu_\eta \). If \( \eta \) is not nullhomologous, then there is a choice of longitude for \( \eta \) and the homeomorphism type of \( M(\eta, K) \) will depend on this choice. Since \( H_1(S^3 - N(K)) \) is independent of \( K \), an easy Mayer-Vietoris argument shows that \( M \) and \( M(\eta, K) \) have isomorphic homology groups.

Now, consider the case when \( M = S^3 - N(L) \) where \( L \) is an \( m \)-component link in \( S^3 \) and \( \eta \) is a curve in \( S^3 - N(L) \subset S^3 \). Even in the case that \( \eta \) is not nullhomologous in \( H_1(S^3 - N(L)) \) there is still a well defined longitude \( l_\eta \) for \( \eta \) since \( \eta \) is nullhomologous in \( S^3 \). By choosing this longitude, we have a well-defined manifold \( M(\eta, K) \). We now further assume that \( \eta \) bounds an embedded disk \( D \) in \( S^3 \). It is well known that in this case, \( M(\eta, K) \) is homeomorphic to \( S^3 - N(L(\eta, K)) \) where \( L(\eta, K) \) is another \( m \)-component link in \( S^3 \). Moreover, one can check that \( L(\eta, K) \) can be obtained by the following construction. Seize the collection of parallel strands of \( L \) that pass through the disk \( D \) in one hand, just as you might grab some hair in preparation for braiding. Then, treating the collection as a single
fat strand, tie it into the knot $K$. Note that in the special case that $\eta$ is a meridian of the $i$th component $L_i$ of $L$ then $L(\eta, K)$ is the link obtained adding a local knot $K$ to $L_i$.

**Remark 5.1.** If $L$ is a boundary link in $S^3$ then $L(\eta, K)$ is also a boundary link in $S^3$. Hence $T(\eta, K)$ is always a boundary link where $T$ is the trivial link.

**Remark 5.2.** Let $M_L$ be the result of performing 0-framed surgery on a link $L$ in $S^3$ with all linking numbers 0 and let $\eta$ be a curve in $S^3 - N(L) \subset M_L$ that bounds an embedded disk in $S^3$. Then $M_L(\eta, K) = M_L$.

**Example 5.3 (Iterated Bing doubles of $K$).** Let $T$ be the trivial link with 2 components and let $\eta_{\text{bing}}$ be the curve in Figure 1. Then $\eta_{\text{bing}}$ bounds a disk in $S^3$. $L(\eta, K)$ is the link in Figure 2 and is more commonly known as the (untwisted) Bing double of $K$, BD($K$). We note that $\eta_{\text{bing}} \in F^{(1)} - F^{(2)}$ where $F = \pi_1(S^3 - N(T))$. Moreover, any (untwisted) iterated Bing double of $K$ can be obtained as $T(\eta, K)$ where $T$ is a trivial link with $m \geq 2$ components and $\eta \in F^{(n)} - F^{(n+1)}$ for some $n \geq 1$.

![Figure 1](image1.png)

**Figure 1.** $\eta_{\text{bing}} \in S^3 - \{\text{trivial link}\}$

![Figure 2](image2.png)

**Figure 2.** Bing double of $K$

We now construct a cobordism $C = C(\eta, K, W)$ between $M$ and $M(\eta, K)$ for which the inclusion maps will behave nicely modulo the torsion-free derived series of their respective fundamental groups. Recall that $M_K$, 0-surgery on $K$ in $S^3$, is defined as $M_K = (S^3 - N(K)) \cup_q ST$ where $ST = S^1 \times D^2$ and $q : \partial(ST) \rightarrow$
In particular, the inclusion map induces isomorphisms between $\pi_1(W)$ and $\pi_1(M)$ generated by $\iota_* (\mu_K)$ where $\iota : M_K \rightarrow W$ is the inclusion map. We have an exact sequence $\pi_2(W) \rightarrow H_2(W) \rightarrow H_2(\pi_1(W))$. Since $\pi_1(W) \cong \mathbb{Z}$, the last term is zero. Hence $H_2(W) = \text{image}(\pi_2(W) \rightarrow H_2(W))$. Using the 4-manifold $W$, we can construct a cobordism $C = C(\eta, K, W)$ between $M$ and $M(\eta, K)$ as follows. Glue $W$, as above, to $M \times I$ by identifying $ST \subset M_K = \partial W$ to $N(\eta) = D^2 \times S^1 \subset M \times \{1\}$ so that $l_{\gamma}^{-1}$ is identified with $\mu_K$ and $\mu_\eta$ is identified to $l_K$. It follows that $\partial C = M \sqcup M(\eta, K)$. Let $i : M \rightarrow C$ and $j : M(\eta, K) \rightarrow C$ be the inclusion maps.

We will use this cobordism to show that the difference between $\rho_0(M)$ and $\rho_0(M(\eta, K))$ depends only on $\rho_0(K)$ and $\max \{ n \mid \eta \in (\pi_1(M))^{(n)} \}$ (see Theorem 5.8 below). We begin with some algebraic lemmas that will be employed in the proof of Theorem 5.8.

**Lemma 5.4.** $i_* : \pi_1(M) \rightarrow \pi_1(C)$ is an isomorphism.

**Proof.** $\pi_1(W) \cong \mathbb{Z}$ which is generated by $\iota_* (\mu_K)$. Moreover, $\mu_K$ generates $\pi_1(W \cap (M \times I)) = \pi_1(\eta \times D^2)$. Hence, by the Seifert-Van Kampen Theorem, $\pi_1(M \times I) \rightarrow \pi_1(C)$, induced by the inclusion map, is an isomorphism. Therefore $i_*$ is an isomorphism. \(\square\)

In particular, the inclusion map induces isomorphisms between $\pi_1(M) / \pi_1(M)_\mu$ and $\pi_1(C) / \pi_1(C)_\mu$ for all $i$. In order to show that $j$ induces an isomorphism between $\pi_1(M(\eta, K)) / \pi_1(M(\eta, K))_\mu$ and $\pi_1(C) / \pi_1(C)_\mu$ for all $i$, we appeal to Theorem 2.4 and Proposition 2.5. The next two lemmas will guarantee that the hypotheses of Proposition 2.5 are satisfied.

**Lemma 5.5.** $j_* : \pi_1(M(\eta, K)) \rightarrow \pi_1(C)$ is an epimorphism.

**Proof.** Let $\alpha$ be a curve in $\pi_1(C)$. By Lemma 5.4, $i_*$ is an isomorphism. Hence $\alpha$ can be represented by a curve in $M$. Moreover, by general position, we can assume $\alpha$ misses $N(\eta)$. Push $\alpha$ into $M \times \{1\}$ to get a curve $\beta$ in $(M \times \{1\}) - (N(\eta) \times \{1\}) \subset M(\eta, K)$ such that $j_* (\beta) = \alpha$. \(\square\)

**Lemma 5.6.** $j_* : \pi_1(M(\eta, K)) \rightarrow \pi_1(C)$ induces an isomorphism on $H_1(-; \mathbb{Z})$ and an epimorphism on $H_2(-; \mathbb{Z})$.

**Proof.** Let $G = \pi_1(M(\eta, K))$ and $E = \pi_1(C)$. Since $j$ induces an epimorphism on $\pi_1$, $j$ induces an epimorphism on $H_1(-)$. The inclusion $l : M - N(\eta) \rightarrow M(\eta, K)$ induces an epimorphism on $H_2(-)$. Moreover, the inclusion $l' : M - N(\eta) \rightarrow M$ induces an epimorphism on $H_1(-)$ and the kernel of $l'_*$ is the subgroup generated by $\mu_\eta \in H_1(M - N(\eta))$.

Consider the following commutative diagram where all of the maps are induced from inclusion maps:

\[
\begin{array}{ccc}
H_1(M - N(\eta)) & \xrightarrow{l'_*} & H_1(M) \\
\downarrow i_* & & \downarrow \cong i_*
\end{array}
\]

\[
\begin{array}{ccc}
H_1(M(\eta, K)) & \xrightarrow{j_*} & H_1(C) \\
\downarrow i_* & & \downarrow \cong i_*
\end{array}
\]

Suppose $\alpha \in H_1(M(\eta, K))$ and $j_* (\alpha) = 0$. Since $l_*$ is surjective, there exists $\gamma \in H_1(M - N(\eta))$ such that $l_*(\gamma) = \alpha$. Hence $i_*(l'_*(\gamma)) = j_*(l_*(\gamma)) = 0$. Since $i_*$ is
injective, \(\gamma \in \ker(l_1)\) so \(\gamma\) is a multiple of \(\mu_\eta\). However, \(l_*(\mu_\eta) = 0\) since in \(M(\eta, K)\), \(\mu_\eta\) is identified with \(l_K\), which bounds a surface in \(S^3 - K \subset M(\eta, K)\). Therefore \(j_* : H_1(M(\eta, K)) \rightarrow H_1(C)\) is a monomorphism. Since \(H_1(M(\eta, K)) = H_1(G)\) (similarly for \(E\)), \(j_* : H_1(G) \rightarrow H_1(E)\) is an isomorphism.

Let \(\alpha \in H_2(E)\), then there exists \(\beta \in H_2(C)\) such that \(k(\beta) = \alpha\) where \(k : H_2(C) \rightarrow H_2(E)\) is the map in the exact sequence

\[
\pi_2(C) \rightarrow H_2(C) \xrightarrow{k} H_2(E) \rightarrow 0.
\]

By a Mayer-Vietoris argument, we see that \(H_2(C) \cong H_2(W) \oplus H_2(M \times I)\) (in the obvious way). Since \(H_2(W) = \im(\pi_2(W) \rightarrow H_2(W))\) and any element of \(\pi_2(W)\) goes to zero under \(k\), we can assume that \(\beta \in H_2(M \times I) \oplus \{0\} \cong H_2(M)\). Let \(S_\beta\) be a surface in \(M\) representing \(\beta\). We will construct a surface \(S'_\beta \subset M(\eta, K)\) such that \(k(j_*([S'_\beta])) = k(i_*([S_\beta])) = \alpha\). This will complete the proof since \(k \circ j_* = j_* \circ k'\)

where \(k' : H_2(M(\eta, K)) \rightarrow H_2(G)\).

We can assume that \(S_\beta\) intersects \(N(\eta)\) in finitely many disks \(D_i\). To construct \(S'_\beta\), remove each of these disks and replace them with a copy of a chosen seifert surface for \(K\) in \(S^3 - K \subset M(\eta, K)\) oriented according the signed intersection of \(\eta\) with \(S_\beta\). Let \(F\) be the surface in \(W \subset C\) obtained by gluing a disk in \((M \times \{1\}) \cap W\) whose boundary is \(\mu_\eta\) with a copy of the chosen seifert surface for \(K\). Since \(H_2(\pi_1(W)) = 0\), \(k([F])\) is trivial in \(H_2(E)\). Moreover \(|S'_\beta| = m[F] + |S_\beta|\) in \(H_2(C)\) for some \(m\) so \(k(j_*([S'_\beta])) = k(i_*([S_\beta]))\).

Note that \(M_K = \partial W \subset C\). For each \(i \geq 0\), let \(\tau : \pi_1(M_K) \rightarrow \pi_1(C)/\pi_1(C)^{(i+1)}\) be the composition of the map induced by inclusion \(\pi_1(M_K) \rightarrow \pi_1(C)\) and the quotient map \(\pi_1(C) \rightarrow \pi_1(C)/\pi_1(C)^{(i+1)}\).

**Lemma 5.7.** If \(\tau : \pi_1(M_K) \rightarrow \pi_1(C)/\pi_1(C)^{(i+1)}\) is the homomorphism as described above then

\[
\text{Im}(\tau_i) \cong \begin{cases} 
\{1\} & 0 \leq i \leq n - 1; \\
\mathbb{Z} & i \geq n.
\end{cases}
\]

**Proof.** Let \(E = \pi_1(C)\). Recall that \(\pi_1(M_K) \cong \pi_1(S^3 - K)/\langle l_K \rangle\) where \(l_K\) is the longitude of \(K\). Hence every element of \(\pi_1(M_K)\) can be represented by \(\alpha = \prod g_i \mu_K g_i^{-1}\) where \(g_i \in \pi_1(S^3 - K)\) and \(\mu_K\) is a fixed meridian of \(K\). Let \(\tau : \pi_1(M_K) \rightarrow E\) be induced by the inclusion of \(M_K\) into \(C\). Since \(\mu_K\) is identified to \(l_K^{-1}\) in \(E\), we see that \(\tau(\alpha) = \prod g_i i_*([l_\eta])^{-1} \tau(g_i)^{-1}\) and \(\tau(\alpha) \in E^{(i)}\) for \(0 \leq i \leq n - 1\). Therefore the image of \(\tau_i\) is trivial for \(0 \leq i \leq n - 1\).

We will prove that the image of \(\tau_i\) is \(\mathbb{Z}\) for \(i \geq n\) by induction on \(i\). First we prove this is true for \(i = n\). Since \(\tau(\pi_1(M_K)) \subset E^{(n)}\), \(\tau([\pi_1(M_K), \pi_1(M_K)]) \subset [E^{(n)}, E^{(n)}] \subset E^{(n+1)}\). Hence we have a well-defined map

\[
\Phi : \mathbb{Z} \cong \pi_1(M_K)/\pi_1(M_K) \rightarrow E/E^{(n+1)}.
\]

Since \(l_\eta \notin P^{(n+1)}\) and \(P/E^{(n+1)} \cong E/E^{(n+1)}\), \(\tau(\mu_K) = i_*([l_\eta]) \notin E^{(n+1)}\). Therefore \(\Phi\) is non-trivial. Moreover, since \(\tau(\pi_1(M_K)) \subset E^{(n)}\), the image of \(\Phi\) is contained in \(E^{(n)}/E^{(n+1)}\) which is \(\mathbb{Z}\)-torsion free. It follows that the image of \(\tau_n\) is isomorphic to \(\mathbb{Z}\).

To finish the induction, assume that the image of \(\tau_i\) is isomorphic to \(\mathbb{Z}\) for some \(i \geq n\). Let \(A = \pi_1(M_K)\); then by Example 3.13 \(A/A^{(j+1)} \cong \mathbb{Z}\) for all \(j \geq 0\).
Suppose Corollary 5.10. \( \rho \) not \( \pi \) and \( \tau \) not \( \pi \) where any iterated Bing double of \( T \) is a non-trivial commutator of length \( m \). Since \( \eta, K \), the map \( \tau_*: A/A^{(i+1)}_{\mu} \to E/E^{(i+1)}_{\mu} \). Since \( A^{(i+1)}_{\mu} = A^{(i+2)}_{\mu} \), the map \( \tau_*: A/A^{(i+2)}_{\mu} \to E/E^{(i+2)}_{\mu} \) is a monomorphism. Therefore the image of \( \tau_{i+1} \) is \( \mathbb{Z} \).

**Theorem 5.8.** Let \( M(\eta, K) \) be as defined in (58) and \( P = \pi_1(M) \). If \( \eta \in P^{(n)} - F_H^{(n)} \) for some \( n \geq 0 \) then

\[
\rho_i(M, \eta, K) = \begin{cases} 0 & 0 \leq i \leq n - 1; \\ \rho_0(K) & i \geq n. \end{cases}
\]

Before proving Theorem 5.8, we establish two easy corollaries.

**Corollary 5.9.** Let \( \eta \) be an embedded curve in \( \#_{i=1}^m S^1 \times S^2 \) that is non-trivial in \( F = \pi_1(\#_{i=1}^m S^1 \times S^2) \). If \( K \) is a knot with \( \rho_0(K) \neq 0 \) then \( \rho_0(K) \neq 0 \). Hence \( \rho_0(K) \neq 0 \). Hence \( \rho_0(K) \neq 0 \). Hence \( \rho_0(K) \neq 0 \). Hence \( \rho_0(K) \neq 0 \). Hence \( \rho_0(K) \neq 0 \).

**Corollary 5.10.** Suppose \( K \) is a knot in \( S^3 \) with \( \rho_0(K) \neq 0 \). Then no iterated Bing double of \( K \) is slice.

**Proof.** Any iterated Bing double of \( K \) can be obtained as \( T(\eta, K) \) where \( \eta \) is a non-trivial commutator of length \( m + 1 \) where \( m \) is the number of components of \( T(\eta, K) \). Therefore, \( \eta \) is a nontrivial element in \( F^{(n)}/F^{(n+1)} \) for some \( n \geq 0 \).

Let \( G = \pi_1(M(\eta, K)) \), \( E = \pi_1(C) \), and \( \Gamma_i = E/E^{(i+1)}_{\mu} \) for \( i \geq 0 \). Since \( C \subset C \), there is an obvious coefficient system \( \pi_1(C) \to \Gamma_i \) (similarly for \( M \)).

Let \( G = \pi_1(M(\eta, K)) \), \( E = \pi_1(C) \), and \( \Gamma_i = E/E^{(i+1)}_{\mu} \) for \( i \geq 0 \). Since \( C \subset C \), there is an obvious coefficient system \( \pi_1(C) \to \Gamma_i \) (similarly for \( M \)).

By Lemmas 5.4-5.5 and 5.6, Theorem 2.4, and Proposition 2.5, \( i_*: P/P^{(i+1)} \to \Gamma_i \) and \( j_*: G/G^{(i+1)} \to \Gamma_i \) are isomorphisms for all \( i \geq 0 \). Therefore, \( \rho_i(M) = \rho(M, \Gamma_i) \) and \( \rho_i(M(\eta, K)) = \rho(M(\eta, K), \Gamma_i) \). Hence we have

\[
(9) \quad \rho_i(M) - \rho_i(M(\eta, K)) + \rho(M, \Gamma_i) = \sigma^{(i)}(C \Gamma_i) - \sigma(C \Gamma_i)
\]

for all \( i \geq 0 \).

Since the abelianization of \( \pi_1(M_K) \) is \( \mathbb{Z} \), there is a unique surjective homomorphism \( \pi_1(M_K) \to \mathbb{Z} \) up to isomorphism. Therefore, by Lemma 5.7 and Lemma 3.7, we have \( \rho(M, \Gamma_i) = \rho_0(M_K) \) for all \( i \geq n \), and \( \rho(M, \Gamma_i) = 0 \) for \( 0 \leq i \leq n - 1 \).
To finish the proof, we will show that \( \sigma^2(C_V, \Gamma_1) - \sigma(C_V) = 0 \) for all \( i \geq 0 \). Since \( U \Gamma_i \) is a flat \( \mathbb{Z} \Gamma_i \)-module it suffices to show that the map induced by the inclusion \( H_2(\partial C_V; \mathbb{Z} \Gamma_i) \to H_2(C_V; \mathbb{Z} \Gamma_i) \) is surjective for \( -1 \leq i \) (recall that \( \Gamma_{-1} = \{1\} \)).

Recall that \( C_V = M_K \times I \cup_{\eta \times D^2} M \times I \). Consider the Mayer-Vietoris sequence

\[
\rightarrow H_2(M_K \times I; \mathbb{Z} \Gamma_i) \oplus H_2(M \times I; \mathbb{Z} \Gamma_i) \rightarrow H_2(C_V; \mathbb{Z} \Gamma_i) \to H_1(\eta \times D^2; \mathbb{Z} \Gamma_i) \rightarrow H_1(M \times I; \mathbb{Z} \Gamma_i) \oplus H_1(M_K \times I; \mathbb{Z} \Gamma_i).
\]

By Lemma 5.4 if \( i \leq n - 1 \) then \( M_K \) lifts to the \( \Gamma_i \)-cover hence \( H_1(M_K \times I; \mathbb{Z} \Gamma_i) \cong \mathbb{Z} \Gamma_i \) is generated by \( \mu_K \). Moreover, in this case, \( \eta \) lifts to the \( \Gamma_i \)-cover and \( H_1(\eta \times D^2; \mathbb{Z} \Gamma_i) \to H_1(M_K; \mathbb{Z} \Gamma_i) \) is an isomorphism. Therefore \( H_2(M_K \times I; \mathbb{Z} \Gamma_i) \oplus H_2(M \times I; \mathbb{Z} \Gamma_i) \to H_2(C_V; \mathbb{Z} \Gamma_i) \) surjective for \( i \leq n - 1 \). If \( i \geq n \), then the image of \( \pi_1(\eta \times D^2) \) in \( \mathbb{Z} \Gamma_i \) is \( \mathbb{Z} \) by Lemma 5.7. Hence \( H_1(\eta \times D^2; \mathbb{Z} \Gamma_i) = 0 \). Thus for \( i \geq n \) we have that \( H_2(M_K \times I; \mathbb{Z} \Gamma_i) \oplus H_2(M \times I; \mathbb{Z} \Gamma_i) \to H_2(C_V; \mathbb{Z} \Gamma_i) \) surjective. It follows that \( H_2(\partial C_V; \mathbb{Z} \Gamma_i) \to H_2(C_V; \mathbb{Z} \Gamma_i) \) is surjective for all \( i \geq -1 \).

5.2. Non-triviality of Examples. For each knot \( K \) in \( S^3 \), there exists a degree one map \( f_K : S^3 - K \to S^4 - T \) (where \( T \) is the unknot) that induces an isomorphism on homology with \( \mathbb{Z} \) coefficients and fixes the boundary. Hence, there is a degree one map \( f_K : M(\eta, K) \to M(\eta, T) = M \) that induces an isomorphism on \( H(\cdot; \mathbb{Z}) \). Recall that \( \mathcal{H}_m^m \) is the set of \( \mathbb{Q} \)-homology cobordism classes of closed, oriented \( m \)-dimensional manifolds. For a fixed closed, oriented \( m \)-dimensional manifold \( M \), we define \( \mathcal{H}_m^m(M) \subset \mathcal{H}_m^m \) as follows: \([N'] \in \mathcal{H}_m^m(M)\) if there exists an \( N \) such that \([N] = [N'] \in \mathcal{H}_m^m\) and there exists a degree one map \( f : N \to M \) that induces an isomorphism on \( H_*(\cdot; \mathbb{Q}) \). By Proposition 5.10 \( \rho_n \) is additive under the connected sum of manifolds. Therefore the images of \( \rho_n : \mathcal{H}_m^m(M) \to \mathbb{R} \) and \( \rho_n : \mathcal{H}_m^m \to \mathbb{R} \) are subgroups of \( \mathbb{R} \).

**Theorem 5.11.** Let \( M \) be a closed, oriented 3-manifold, \( G = \pi_1(M) \) and \( n \geq 0 \). If \( G_n^m/G_n^{m+1} \neq \{1\} \) then the image of \( \rho_n : \mathcal{H}_m^m(M) \to \mathbb{R} \) is (1) dense in \( \mathbb{R} \) and (2) an infinitely generated subgroup of \( \mathbb{R} \). In particular, the image of \( \rho_n : \mathcal{H}_m^m \to \mathbb{R} \) is (1) dense in \( \mathbb{R} \) and (2) an infinitely generated subgroup of \( \mathbb{R} \).

**Proof.** Let \( -2 < r < 2 \). By [3] Section 2], for all \( \epsilon > 0 \), there exists a knot \( K_{r, \epsilon} \) in \( S^3 \) such that

\[
\left| \int_{S^1} \sigma_\omega(K_{r, \epsilon})d\omega - r \right| < \epsilon.
\]
Here, $\sigma_\omega(K)$ is the Levine-Tristram signature of $K$ at $\omega \in S^1$ and the circle is normalized to have length 1. By [11] Lemma 5.4, $\rho_0(M_K) = \int_{S^1} \sigma_\omega(K) d\omega$ for any knot $K$ in $S^3$. Let $\rho$ be a curve in $M$ representing an element in $G^{(n)}_H - G^{(n+1)}_H$. Then by Theorem 5.11, $\rho_n(M(\eta, K)) = \rho_0(M_K)$. Moreover, by the above remarks, there is a degree one map from $M(\eta, K)$ to $M$ hence $r \in \rho_n(H^3_Q(M))$.

For arbitrary $r \in \mathbb{R}$ there exists a positive integer $m$ such that $r/m \in (-2, 2)$. Let $\epsilon > 0$ and set $\epsilon' = \epsilon/m$. As above, there exists a knot $K_{r/m, \epsilon'}$ such that $|\rho_0(M_{K_{r/m, \epsilon'}}) - r/m| < \epsilon'$. We remark that $K_1 \# K_2$ can be obtained as $M_{K_1}(\eta, K_2)$ where $\eta$ is a meridian of $K_1$ in $M_{K_1}$. Hence by Theorem 5.11, $\rho_0(M_{K_1} \# K_2) = \rho_0(M_{K_1}) + \rho_0(M_{K_2})$ (this can also be computed directly). Hence $\rho_0(M_{mK}) = m\rho_0(M_K)$ where $mK$ is the connected sum of $K$ with itself $m$ times. Therefore

$$|\rho_0(M_{mK_{r/m, \epsilon'}}) - r| = m |\rho_0(M_{K_{r/m, \epsilon'}}) - r/m| < m\epsilon' = \epsilon.$$

As before, it follows that $r \in \rho_n(H^3_Q(M))$. This completes the verification that the image of $\rho_n$ is dense in $\mathbb{R}$.

By Proposition 2.6 of [12], there exists an infinite set \{J_i|i \in \mathbb{Z}_+\} of Arf invariant zero knots such that \{\rho_0(M_{J_i})\} is linearly independent over the integers. Therefore \{\rho_n(M(\eta, J_i))\} is an infinitely generated subgroup of $\mathbb{R}$. Since $\rho_n(H^3_Q(M))$ is an abelian group that contains this subgroup, it is itself infinitely generated.

Let $T$ be a trivial link. If $L$ is a boundary link then, just as for a knot, there is a degree one map $S^3 - L$ to $S^3 - T$ that fixes the boundary and induces an isomorphism on homology. In particular, there is a degree one map from the 0-surgery on a boundary link with $m$ components to the connected sum of $m$ copies of $S^1 \times S^2$ that induces an isomorphism on homology. Thus, for each $m \geq 1$, we can consider the subset $H^{3,b}_Q(m) \subset H^3_Q(\#_{i=1}^m S^1 \times S^2)$ defined by $[N'] \in H^{3,b}_Q$ if $[N'] = [N] \in H^{3}_Q$ where $N$ is 0-surgery on a boundary link in $S^3$. As before, for each $n$ and $m$, the image of $\rho_n : H^{3,b}_Q(m) \rightarrow \mathbb{R}$ is a subgroup of $\mathbb{R}$.

**Corollary 5.12.** For each $n \geq 0$ and $m \geq 2$, the image of $\rho_n : H^{3,b}_Q(m) \rightarrow \mathbb{R}$ is

1. dense in $\mathbb{R}$ and
2. an infinitely generated subgroup of $\mathbb{R}$.

**Proof.** Let $M$ be the manifold obtained by performing 0-surgery on the trivial link with $m \geq 2$ components. Then $M = \#_{i=1}^m S^1 \times S^2$ and $\pi_1(M) \cong F(m)$. Since $F_n^{(n)} / F_n^{(n+1)} = F^{(n)} / F^{(n+1)}$ is non-trivial for $n \geq 0$, there exists an $\eta \in F_n^{(n)} / F_n^{(n+1)}$. We can assume that $\eta \in \pi_1(S^3 - T)$ where $T$ is the trivial link in $S^3$ since the inclusion $S^3 - T \rightarrow M$ induces an isomorphism on $\pi_1$. Moreover, we can alter $\eta$ by a homotopy in $S^3 - T$ to obtain a curve $\eta'$ that bounds a disk in $S^3$. Thus, as we showed in the proof of Theorem 5.11, the image of $\rho_n : \{M(\eta', K)|K$ is a knot in $S^3\} \subset H^{3,b}_Q(m) \rightarrow \mathbb{R}$ is dense in $\mathbb{R}$ and is an infinitely generated subgroup of $\mathbb{R}$.

We will now show that the $\rho_n$ are independent functions. For each $m \geq 2$, let $V_m = \{f : H^{3,b}_Q(m) \rightarrow \mathbb{R}\}$, be the vector space of functions from the set $H^{3,b}_Q(m)$ to $\mathbb{R}$ and $V = \{f : H^4_Q \rightarrow \mathbb{R}\}$ be the vector space of functions from $H^4_Q$ to $\mathbb{R}$.

**Theorem 5.13.** For each $m \geq 2$, $\{\rho_n\}_{n=0}^\infty$ is a linearly independent subset of $V_m$. In particular, $\{\rho_n\}_{n=0}^\infty$ is a linearly independent subset of $V$.

**Proof.** Let $\alpha = r_1 \rho_{i_1} + \cdots + r_k \rho_{i_k}$ where $r_i$ are non-zero real numbers, $\rho_{i_j} : H^{3,b}_Q(m) \rightarrow \mathbb{R}$ and $i_j < i_j'$ if $j < j'$. Suppose $\alpha = 0$. Let $M$ be 0-surgery on
the \( m \)-component trivial link \( T \) in \( S^3 \) and \( F = \pi_1(M) \). As in the proof of Corollary 5.12 above, for each \( n \geq 0 \), there is a curve \( \eta_n \) in \( S^3 - T \) such that \( \eta_n \) bounds a disk in \( S^3 \) and \( \eta_n \in F^{(n)} - F^{(n+1)} \). For each \( n \geq 0 \), let \( M_n = M(\eta_n, K) \) for some \( K \) with \( \rho_0(M_K) \neq 0 \) (for example, let \( K \) be the right handed trefoil). By the remarks above Corollary 5.12, \( M_n \subset H^3_{\partial Q} \). By Theorem 5.8, \( \rho_i(M_n) = 0 \) for \( i \leq n - 1 \) and \( \rho_n(M_n) \neq 0 \). Hence \( 0 = \alpha(M_{ik}) = r_k \rho_{ik}(M_{ik}) \). Since \( \rho_{ik}(M_{ik}) \neq 0 \), \( r_k = 0 \). This is a contradiction. \( \square \)

6. THE GROPE AND \((n)\)-SOLVABLE FILTRATIONS

We now investigate the grope and \((n)\)-solvable filtrations of the string link concordance group (with \( m \geq 2 \) strands) first defined for knots by T. Cochran, K. Orr and P. Teichner in [11]. We will show that the function \( \rho_n \) is a homomorphism on the subgroup of boundary links and vanishes for \((n+1)\)-solvable links. Using this, we will show that each of the successive quotients of the \((n)\)-solvable filtration of the string link concordance group contains an infinitely generated subgroup (even modulo local knotting). We will also show that a similar statement holds for the grope filtration of the string link concordance group. The reason that we study string links instead of ordinary links is that the connected sum operation for ordinary links is not well-defined. Thus, in order to have a group structure on the set of links up to concordance, we must use string links.

We begin by recalling some definitions. Recall that an \textbf{m-component string link} (sometimes called an m-component disk link [23] [15]) is a locally flat embedding \( f : \sqcup_m I \to D^3 \) of \( m \) oriented, ordered copies of \( I \) in \( D^3 \) that is transverse to the boundary and such that \( f|\sqcup_m \partial I \) is the standard m-component trivial 0-link in \( S^2 \), \( j_0 : \sqcup_m \partial I \to S^2 \). Two \( m \)-component string links \( f, g \) are \textbf{concordant} if there exists a locally flat embedding \( F : \sqcup_m I \times I \to D^3 \times I \) that is transverse to the boundary and such that \( F|\sqcup_m I \times \{0\} = f, F|\sqcup_m I \times \{1\} = g \) and \( F|\sqcup_m \partial I \times I = j_0 \times \text{id}_I \). The concordance classes of \( m \)-component string links forms a group under stacking (see Figure 5 which we denote by \( C(m) \) (see [15] for more details). In the literature this group is often denoted \( C(m, 1) \) or \( CSL(m) \). This group is known to be non-abelian when \( m \geq 2 \) [15] and abelian when \( m = 1 \). Let \( B(m) \) be the subgroup of boundary disk links in \( C(m) \)
If \( L \) is a string link then the closure of \( L \), denoted by \( \hat{L} \), is the oriented, ordered \( m \)-component link in \( S^3 \) obtained by adjoining to its boundary the standard trivial string link. A string link is equipped with a well-defined set of meridians that we denote by \( \mu_1, \ldots, \mu_m \).

6.1. \((n)\)-solvable filtration of \( C(m) \). In [11, Definition 8.7, p. 503] Cochran, Orr, and Teichner define an \((n)\)-solvable knot and link where \( n \in \frac{1}{2} \mathbb{N}_0 \). We recall the definitions here. We first recall the definition of an \((n)\)-Lagrangian. Let \( M \) be a fixed closed, oriented 3-manifold. An \( H_1\)-bordism is a 4-dimensional spin manifold \( W \) with boundary \( M \) such that the inclusion map induces an isomorphism \( H_1(M) \cong H_1(W) \). For any 4-manifold \( W \), let \( W^{(n)} \) denote the regular covering of \( W \) that corresponds to the \( n \)-th term of the derived series of \( \pi_1(W) \). For each \( n \geq 0 \), one can define the quadratic forms \( \lambda_n, \mu_n \) on \( H_2(W^{(n)}) \) in terms of equivariant intersection and self-intersection numbers of surfaces in \( W \) that lift to the cover \( W^{(n)} \). If \( F \) is a closed, oriented, immersed, and based surface in \( W \) that lifts to \( W^{(n)} \) then \( F \) is called an \( (n)\)-surface. See [11, Chapter 7, pp. 493–496] for the precise definitions.

**Definition 6.1.** Let \( W \) be an \( H_1\)-bordism such that \( \lambda_0 \) is a hyperbolic form.

1. A Lagrangian for \( \lambda_0 \) is a direct summand of \( H_2(W) \) of half rank on which \( \lambda_0 \) vanishes.
2. An \((n)\)-Lagrangian is a submodule \( L \subset H_2(W^{(n)}) \) on which \( \lambda_n \) and \( \mu_n \) vanish and which maps onto a Lagrangian of the hyperbolic form \( \lambda_0 \) on \( H_2(W) \).
3. Let \( k \leq n \). We say that an \((n)\)-Lagrangian \( L \) admits \((k)\)-duals if \( L \) is generated by \((n)\)-surfaces \( l_1, \ldots, l_g \) and there are \((k)\)-surfaces \( d_1, \ldots, d_g \) such that \( H_2(W) \) has rank \( 2g \) and

\[
\lambda_k(l_i, d_j) = \delta_{ij}.
\]

We now define \((n)\)-solvability for a 3-manifold or link in \( S^3 \).

**Definition 6.2.** Let \( M \) be a closed, oriented 3-manifold and \( n \in \mathbb{N} \). \( M \) is called \((0)\)-solvable if it bounds an \( H_1\)-bordism \( W \) such that \((H_2(W), \lambda_0)\) is hyperbolic. \( M \) is called \((n)\)-solvable for \( n > 0 \) if there is an \( H_1\)-bordism \( W \) for \( M \) that contains an \((n)\)-Lagrangian with \((n)\)-duals. The 4-manifold \( W \) is called an \((n)\)-solution for \( M \). A link \( L \) in \( S^3 \) is said to be \((n)\)-solvable if the zero surgery on \( L \) is \((n)\)-solvable. A string link \( L \in C(m) \) is said to be \((n)\)-solvable if \( \hat{L} \) is \((n)\)-solvable.

**Definition 6.3.** Let \( M \) be a closed, oriented 3-manifold and \( n \in \mathbb{N} \). \( M \) is said to be \((n, 5)\)-solvable if there is an \( H_1\)-bordism for \( M \) that contains an \((n+1)\)-Lagrangian with \((n)\)-duals. The 4-manifold is called an \((n, 5)\)-solution. A link \( L \) in \( S^3 \) is said to be \((n, 5)\)-solvable if the zero surgery on \( L \) is \((n, 5)\)-solvable. A string link \( L \in C(m) \) is said to be \((n, 5)\)-solvable if \( \hat{L} \) is \((n, 5)\)-solvable.

Hence, for each \( m \geq 1 \), we can define a filtration of the string link concordance group

\[
\cdots \subset F^{m}_{(n, 5)} \subset F^{m}_{(n)} \subset \cdots \subset F^{m}_{(0, 5)} \subset F^{m}_{(0)} \subset C(m)
\]

by setting \( F^{m}_{(n)} \) to be the set of \((n)\)-solvable \( L \in C(m) \) for \( n \in \frac{1}{2} \mathbb{N}_0 \). It is easy to check that \( F^{m}_{(n)} \) is a subgroup of \( C(m) \) and in fact is a normal subgroup of \( C(m) \) for each \( m \in \mathbb{N} \) and \( n \in \frac{1}{2} \mathbb{N}_0 \).
When $m = 1$, $C(1)$ is the concordance group of knots which is an abelian group. It was shown in [11] that $C/F_{(0)} \cong \mathbb{Z}_2$ given by the Arf invariant and $C/F_{(0,5)}$ is J. P. Levine’s algebraic concordance group which is isomorphic to $\mathbb{Z}^\infty \oplus \mathbb{Z}_2^\infty \oplus \mathbb{Z}_4^\infty$ [22]. It was also shown in [11, 12] that $F_{(n)}/F_{(n,5)}$ for $n = 1, 2$ has infinite rank. Moreover, in [13], Cochran and Teichner showed that for each $n \in \mathbb{N}$, $F_{(n)}/F_{(n,5)}$ is of infinite order. However, it is still unknown whether $F_{(n)}/F_{(n,5)}$ has infinite rank for $n \geq 3$.

For $m \geq 2$, we will show that for all $n \in \mathbb{N}_0$, $F_{(n)}/F_{(n+1)}$ contains an infinitely generated subgroup, the subgroup “generated by boundary links” defined as follows. We define the $(n)$-solvable filtration of $B(m)$, the subgroup of boundary string links, by

$$B_{\mathcal{F}^m(n)} \cong B(m) \cap \mathcal{F}^m(n).$$

Then for each $n \geq 0$, $B_{\mathcal{F}^m(n)}/B_{\mathcal{F}^m(n+1)}$ is a subgroup of $\mathcal{F}^m(n)/\mathcal{F}^m(n+1)$. We will show that the abelianization of $B_{\mathcal{F}^m(n)}/B_{\mathcal{F}^m(n+1)}$ has infinite rank. It would be very interesting to know whether $B_{\mathcal{F}^m(n)}/B_{\mathcal{F}^m(n,5)}$ is infinitely generated. It would be even more interesting to exhibit non-trivial links in $B_{\mathcal{F}^m(n)}/B_{\mathcal{F}^m(n+1)}$. To show that $B_{\mathcal{F}^m(n)}/B_{\mathcal{F}^m(n+1)}$ is infinitely generated, we show that $\rho_n$ is a homomorphism on the subgroup $B(m)$ and that $\rho_n$ vanishes on $(n + 1)$-solvable links. We begin with the latter.

**Theorem 6.4.** If a 3-manifold $M$ is $(n)$-solvable then for each $(n)$-solution $W$ and $k \leq n$, the inclusion $i : M \to W$ induces monomorphisms

$$i_* : H_1(M; K(\pi_1(W)/\pi_1(W)/(k+1))) \to H_1(W; K(\pi_1(W)/\pi_1(W)/(k+1))),$$

and

$$i_* : \pi_1(M)/(k+1) \to \pi_1(W)/(k+1);$$

and

$$\rho_{k-1}(M) = 0.$$

Thus, if $L \in F_{(n)}$ then $\rho_{k-1}(L) = 0$ for $k \leq n$.

**Proof.** Let $W$ be an $(n)$-solution for $M$, $G = \pi_1(M)$, and $E = \pi_1(W)$. We will prove the result by induction on $k$. The result is clearly true for $k = 0$ (here $\rho_{-1}(M) = 0$ for any $M$). Assume the result is true for some $k \leq n - 1$.

Let $W_{(k+1)}$ be the regular cover of $W$ corresponding to $E_{(k+1)}$, the $k^{th}$ term of the torsion-free derived series of $E$. Since $E_{(n)} \subset E_{(n)} \subset E_{(k+1)}$, $W$ admits a “torsion-free $(k + 1)$-Lagrangian” with “torsion-free $(k + 1)$-duals.” Specifically, there are intersection and self-intersection forms $\lambda_{k+1}$ and $\mu_{k+1}$ on $H_2(W_{(k+1)})$. We project the $(n)$-Lagrangian $L$ and $(n)$-duals for $L$ to $H_2(W_{(k+1)})$ to get “torsion free $(k + 1)$-surfaces” $l_1, \ldots, l_g, d_1, \ldots, d_g$ such that

$$\lambda_{k+1}(l_i, l_j) = 0 \quad \text{and} \quad \lambda_{k+1}(l_i, d_j) = \delta_{ij}$$

for $1 \leq i, j \leq g$. 

Recall that for a group $E$, $E_{k+1} = E/E_{k+1}^{(k+1)}$. We will show that $\{l_1, \ldots, l_g, d_1, \ldots, d_g\}$ is a $\Z E_{k+1}$-linearly independent set in $H_2(W_{k+1})$. Suppose
\[
0 = \sum_{i=0}^{g} m_i l_i + n_i d_i
\]
for some $m_i, n_i \in \Z E_{k+1}$. Then applying $\lambda^H_{k+1}(l_j, -)$ we get
\[
0 = \sum_{i=0}^{g} m_i \lambda^H_{k+1}(l_j, l_i) + n_i \lambda^H_{k+1}(l_j, d_i) = n_j
\]
for $1 \leq j \leq g$. We now apply $\lambda^H_{k+1}(-, d_j)$ to the new equality $0 = \sum_{i=0}^{g} m_i l_i$ to get $m_j = 0$ for all $1 \leq j \leq g$. Therefore $\{l_i, d_i | 1 \leq i \leq g\}$ is a linearly independent set. Thus $\{l_1, \ldots, l_g, d_1, \ldots, d_g\}$ generates a rank 2 free $\Z E_{k+1}$-submodule of $H_2(W_{k+1})$. Moreover, since
\[
\text{rank}_{\Z E_{k+1}} H_2(W; \Z E_{k+1}) \leq \beta_2(W) = 2g,
\]
by Proposition 4.3 of [11]. $\{l_1, \ldots, l_g, d_1, \ldots, d_g\}$ generates $H_2(W; \Z E_{k+1})$ as a $\Z E_{k+1}$-module. In particular, $H_2(W; \Z E_{k+1})$ is a rank $\beta_2(W) = 2g$.

Consider the homomorphism $\overline{\theta}_{W,E_{k+1}} : H_2(W; \Z E_{k+1}) \to H_2(W; \Z E_{k+1})^*$ defined by replacing the coefficients $\U \Lambda$ in Section 2.3 with $\Lambda$ where $\Lambda = E_{k+1}$. Since $\overline{\theta}_{W,E_{k+1}}(d_i)(l_j) = \lambda_{k+1}(l_i, d_j) \otimes \Z E_{k+1} = \delta_{ij}$ and $\overline{\theta}_{W,E_{k+1}}(l_i)(l_j) = \lambda_{k+1}(l_i, l_j) \otimes \Z E_{k+1} = 0$ for $1 \leq i, j \leq g$, we can use the same argument as before to show that if $\overline{\theta}_{W,E_{k+1}}(\sum_{i=0}^{g} m_i l_i + n_i d_i) = 0$ then $m_i = n_i = 0$ for all $1 \leq i \leq g$. Hence $\overline{\theta}_{W,E_{k+1}}$ is a monomorphism. However, since $\overline{\theta}_{W,E_{k+1}}$ is a monomorphism between modules of the same rank, $\overline{\theta}_{W,E_{k+1}}$ is an isomorphism. In particular, the map $H_2(W; \Z E_{k+1}) \to H_2(W; \Z E_{k+1})$ is surjective which implies that the map $H_1(M; \Z E_{k+1}) \to H_1(W; \Z E_{k+1})$ is a monomorphism. Hence, by Theorem 2.4,
\[
(14) \quad \overline{i}_* : \frac{\pi_1(M)}{\pi_1(M)^{[k+2]}_H} \to \frac{\pi_1(W)}{\pi_1(W)^{[k+2]}_H}
\]
is a monomorphism. Moreover, $(W, \phi_k : E \to E_{k+1}, i_* : G_{k+1} \to E_{k+1})$ is therefore an s-nullbordism for $(M, \phi_k : G \to G_{k+1})$. By definition, $\rho_k(M) = \sigma^{(2)}(W, E_{k+1}) - \sigma(W)$.

Since $\sigma(W) = 0$, to complete the proof, we show that $\sigma^{(2)}(W, E_{k+1}) = 0$. Recall that $H_2(W; M; \Z E_{k+1}) \cong H_2(M; \Z E_{k+1})^* \cong (\K E_{k+1})^{2g}$ where the isomorphism is given by the composition of the Poincare duality and Kronecker map. Thus $H_2(W; \Z E_{k+1}) \to H_2(W; M; \Z E_{k+1})$ is a surjective map between finitely generated $\K E_{k+1}$-modules of the same rank; hence is an isomorphism. Since $E_{k+1}$ is an Ore domain, $\U E_{k+1}$ is flat as a right $\K E_{k+1}$-module hence $H_2(W; \U E_{k+1}) \to H_2(W; M; \U E_{k+1})$ is an isomorphism. By naturality, the $(k + 1)$-Lagrangian above also becomes a metabolizer for $h_{W,E_{k+1}}$ with $\U E_{k+1}$ coefficients. Therefore, $h_{W,E_{k+1}}$ is a nonsingular pairing with metabolizer so by Lemma 3.1 $\sigma^{(2)}(W, E_{k+1}) = 0$.

We now show that $\rho_n$ is additive on boundary links. We begin with an algebraic lemma that will be useful in the proof.

**Lemma 6.5.** Let $A$ be a finitely related related group, $E$ be a finitely generated group and $i : A \to E$ be a monomorphism that induces an isomorphism on $H_1(-; \Q)$. If there is a retract $r : E \to A$ then for each $n \geq 0$, both $i$ and $r$ induce an isomorphism
i_n : A/A_n \to E/E_{n} and r_n : E/E_{n} \to A/A_{n} respectively. Moreover, for each 
\[ n \geq 0, \]
\[
\text{rank}_{\kappa(E/E_{n}^{(n)})} H_{1}(E; K(E/E_{n}^{(n)})) = \text{rank}_{\kappa(A/A_{n}^{(n)})} H_{1}(A; K(A/A_{n}^{(n)})).
\]

Proof. Since \( r \) is a retract and \( i \) induces an isomorphism on \( H_{1}(\mathbb{Q}) \), \( r \) induces an isomorphism on \( H_{1}(\mathbb{Q}) \) and a surjective map \( H_{2}(\mathbb{Q}) \). Hence, by Theorem 4.1 of [6] (see also Theorem 2.4 and Proposition 2.5 of this paper), \( r \) induces isomorphisms \( r_{n} : E/E_{n}^{(n)} \to A/A_{n}^{(n)} \) for all \( n \geq 0 \). We will prove \( i \) induces monomorphisms \( i_{n} : A/A_{n}^{(n)} \to E/E_{n}^{(n)} \) by induction. This is clear when \( n = 0, 1 \). Assume that the result holds for some \( n \geq 1 \), then by Proposition 2.2, \( i \) induces a homomorphism \( i_{n+1} : A/A_{n+1}^{(n+1)} \to E/E_{n+1}^{(n+1)} \) and for each \( \alpha \). Assume that the result holds for some \( n \geq 1 \), then by Proposition 2.2, \( i \) induces a homomorphism \( i_{n+1} : A/A_{n+1}^{(n+1)} \to E/E_{n+1}^{(n+1)} \) and for each \( \alpha \).

If \( L_1 \) and \( L_2 \) are \( m \)-component string links then \( L_1 L_2 \) is the \( m \)-component string link obtained by stacking \( L_1 \) on top of \( L_2 \) as depicted in Figure 5. This stacking operation induces the multiplication in the group \( \mathcal{C}(m) \).

![Figure 5. The product of \( L_1 \) and \( L_2 \), \( L_1 L_2 \)](image)

**Proposition 6.6.** If \( L_1, L_2 \in \mathcal{C}(m) \) and \( \hat{L}_1, \hat{L}_2 \) are boundary links then for each 
\[ n \geq 0, \]
\[
\rho_n(L_1 L_2) = \rho_n(L_1) + \rho_n(L_2).
\]

**Proof.** If \( \hat{L}_1 \) and \( \hat{L}_2 \) are boundary links then \( \hat{L}_1 \hat{L}_2 \) is also a boundary link. Let \( M_1, M_2 \) and \( M' \) be the closed 3-manifolds obtained by performing 0-framed Dehn surgery on \( \hat{L}_1, \hat{L}_2 \) and \( \hat{L}_1 \hat{L}_2 \) respectively. Let \( M' \) be the 3-manifold obtained by performing 0-framed Dehn surgery along the curves \( \alpha_1, \ldots, \alpha_n \) in \( M_1 \# M_2 \) as in Figure 6. We will show that \( M' \) is homeomorphic to \( M \). To see this, we first isotope the curve \( c \) in \( M' \) (by a “handle slide”) to obtain the 3-manifold on the left-hand side of Figure 7. Note that by \( \hat{L}_i \), we mean the \( (m+1) \)-component string link obtained from \( L_i \) by adding a copy of the “first string” by doing a 0-framed pushoff. Then by doing a slam-dunk [9, The Slam-Dunk Theorem, p.15] move on the middle surgery diagram of Figure 7 we see that \( M' \) is homeomorphic to the 3-manifold on the right-hand side of Figure 7. We continue this process until we arrive at the surgery description of \( M' \) in Figure 8. Hence \( M' \) is homeomorphic to \( M \).

Thus \( (M_1 \# M_2) \cup \partial V = \partial W \) where \( W \) is a 4-dimensional manifold that is obtained by adding 0-framed 2-handles to \( (M_1 \# M_2) \times I \) along the curves \( \alpha_1 \times \{1\}, \ldots, \alpha_m \times \{1\} \).
Figure 6. The 3-manifolds $M_1 \# M_2$ and $M'$

Figure 7.

Figure 8. The 3-manifold $M$, that is homeomorphic to $M'$
{1}. Let $E = \pi_1(W)$, $A = \pi_1(M_1)$, $B = \pi_1(M_2)$ and $\mu_i, \ldots \mu_m$ be the standard meridians of $L_j$ included into $M_j$. Then

$$E \cong A \ast B/\langle \mu_i, \ldots, \mu_m \rangle.$$

Recall that $M_1 \cup M_2 \cup \partial M_1 \# M_2 = \partial W'$ where $W'$ is obtained by adding a 1-handle to $(M_1 \cup M_2) \times I$. Let $V = W \cup M_1 \# M_2$ $W'$ then $\partial V = M_1 \cup M_2 \cup M$ and the inclusion map of $W$ into $V$ induces an isomorphism $\pi_1(V) \cong \pi_1(W)$. Let $i, j$ and $k$ be the inclusion maps of $M_1, M_2$ and $M$ into $V$ respectively and let $\Gamma_n = E/E^{(n+1)}_n$.

To complete the proof we will show that (1) $i_* : A \to E$ (similarly for $j, k$) induces an isomorphism $A/A^{(n+1)} \to \Gamma_n$ and (2) $\sigma_{(V, \Gamma_n)} - \sigma(V) = 0$ for each $n \geq 0$. Thus, $\rho_n(M_1) + \rho_n(M_2) = \rho_n(M).

We first prove (1). Let $F = \langle x_1, \ldots, x_m \rangle$ be the free group on $m$ generators and $i_B : F \to B$ and $i_A : F \to A$ be the inclusion maps of sending $x_i \mapsto \mu_i$. Then $E \cong A \ast F B$. Since $B$ is the fundamental group of 0-surgery on a boundary link, there is a retract $r_B : B \to F$ giving a retract $r : E \to A$ where the inclusion is $i_A$ as above. Therefore, by Lemma 6.5, $A/A^{(n+1)} \to \Gamma_n$ is a monomorphism for all $n \geq 0$. The proof for $B$ is the same as for $A$.

Let $G = \pi_1(M)$. We will show that $k_* : G \to E$ induces an isomorphism $G/G^{(n)}(\alpha) \to E/E^{(n)}(\alpha)$ for each $n \geq 0$. Since $A$ has a retract to $F$ and $i_A$ induces an isomorphism on $H_1$ by Lemma 6.5, $\text{rank}_{K_{\alpha}} H_1(A; K_{\alpha}) = \text{rank}_{K_{\alpha}} H_1(F; K_{\alpha}) = m - 1$ for all $n \geq 0$. Similarly, $\text{rank}_{K_{\alpha}} H_1(A; K_{\alpha}) = \text{rank}_{K_{\alpha}} H_1(E; K_{\alpha})$. Hence, for all $n \geq 0$, $\text{rank}_{K_{\alpha}} H_1(E; K_{\alpha}) = m - 1$. Since $G$ is also the fundamental group of 0-surgery on a boundary link, $\text{rank}_{K_{\alpha}} H_1(G; K_{\alpha}) = m - 1$.

We will show by induction on $n$ that $k_* : G \to E$ induces an isomorphism $H_1(G; K_{\alpha}) \to H_1(E; K_{\alpha})$ for all $n \geq 0$. First, $E = G/\langle [\mu_i, g_0] \rangle$ where $\mu_i$ are the given meridians for the string link $L_1 L_2$ included into $G$. Hence $H_1(G; K_{\alpha}) \to H_1(E; K_{\alpha})$ is an isomorphism. Now, assume that $H_1(G; K_{\alpha}) \to H_1(E; K_{\alpha})$ is an isomorphism for all $k \leq n$. By Theorem 2.3, $G/G^{(n+1)} \cong E/E^{(n+1)}$ is an isomorphism. Hence, $\text{rank}_{K_{\alpha}} H_1(G; K_{\alpha}) = \text{rank}_{K_{\alpha}} H_1(E; K_{\alpha}) = m - 1$. Since $k_* : G \to E$ is surjective, $k$ induces a surjective map $H_1(G; K_{\alpha}) \to H_1(E; K_{\alpha})$ between $K_{\alpha}$-modules of the same rank; hence is an isomorphism. Thus, for each $n \geq 0$, $G/G^{(n+1)} \to E/E^{(n+1)}$ is an isomorphism by Theorem 2.3.

To prove (2), note that there is an exact sequence coming from the long exact sequence of the pair $(W, M_-)$ with coefficients in $K(\Gamma_n)$

$$0 \to \text{Im}(\alpha) \to H_2(W, M_-) \to H_1(M_-) \to H_1(W) \to H_1(W, M_-) \to 0$$

where $M_- = M_A \cup M_B$ and $\alpha : H_2(W) \to H_2(W, M_A \cup M_B)$. Since $W$ is obtained by adding a 1-handle and $m$ 2-handles to $M_- \times I$, $\text{rank}_{K_{\alpha}} H_2(W, M_-) = \text{rank}_{K_{\alpha}} H_1(W, M_-) = m - 1$. Since $\text{rank}_{K_{\alpha}} H_1(W) = m - 1$ and $\text{rank}_{K_{\alpha}} H_1(M_-) = 2m - 2$, it follows that $\text{rank}_{K_{\alpha}} \text{Im}(\alpha) = 0$. Hence $H_2(M_-) \to H_2(W)$ is a surjective homomorphism.

**Corollary 6.7.** For each $n \geq 0$ and $m \geq 1$, $\rho_n : \mathcal{B}(m) \to \mathbb{R}$ is a homomorphism.

We now establish the main theorems of this paper.

**Theorem 6.8.** For each $n \geq 0$ and $m \geq 2$, the abelianization of $\mathcal{B}F^{m}_n/\mathcal{B}F^{m}_{n+1}$ has infinite rank. In particular, for $m \geq 2$, $\mathcal{B}F^{m}_n/\mathcal{B}F^{m}_{n+1}$ is an infinitely generated subgroup of $F^{m}_n/F^{m}_{n+1}$.
Proof. Let $T$ be the $m$-component trivial link in $S^3$ with $m \geq 2$ then $F = \pi(S^3 - T) = \pi_1(M_T)$ is free group on $m$-generators. Let $\eta$ be a curve in $S^3 - T$ such that $\eta$ is a trivial knot and the homotopy class of $\eta$ is in $F(n) - F(n+1)$. Define
\begin{equation}
S_\eta = \{T(\eta, K) \mid K \text{ is a knot in } S^3 \text{ with Arf invariant zero}\} \subset B(m).
\end{equation}
Since the trivial link is $(n)$-solvable, by the proof Proposition 3.1 of [12] (this result holds if one replaces $(n)$-solvable knot with $(n)$-solvable link), $T(\eta, K)$ is $(n)$-solvable if the Arf invariant of $K$ is 0. Hence $S_\eta \subset BF_{(n)}^m$. By Theorem 6.8, $\rho_n$ vanishes on $F_{(n+1)}^m$. Therefore
\[
\rho_n : \frac{BF_{(n)}^m}{BF_{(n+1)}^m} \to \mathbb{R}
\]
is a homomorphism.

By Proposition 5.8, $\rho_n(T(\eta, K)) = \rho_0(K)$. Moreover, by Proposition 2.6 of [12], there is an infinite set of Arf invariant zero knots $\{J_i\}$ such that $\{\rho_0(J_i)\}$ is $\mathbb{Z}$-linearly independent. Since $\mathbb{R}$ is abelian, this implies that the abelianization of $BF_{(n)}^m/BF_{(n+1)}^m$ has infinite rank. \qed

Since adding a local knot to $L \in B(m)$ doesn’t change $\rho_n - \rho_0$, we can show that $BF_{(n)}^m/BF_{(n+1)}^m$ is infinitely generated “modulo local knotting.” We make this precise starting with the following definition. Let $K(m)$ be the subgroup of $B(m)$ of split string links. $K(m)$ is a normal subgroup of $C(m)$ and hence a normal subgroup of $B(m)$. For each $n \geq 0$, define $KF_{(n)}^m = F_{(n)}^m \cap K(m)$. Then $KF_{(n+1)}^m$ is a normal subgroup of $KF_{(n)}^m$ and $KF_{(n)}^m/KF_{(n)}^m$ is a normal subgroup of $BF_{(n)}^m/BF_{(n+1)}^m$. Note that adding a local knot to $L \in B(m)$ is the same as multiplying $L$ by an element of $K(m)$. As a corollary of the proof of Theorem 6.8 we have the following result.

**Corollary 6.9** (Theorem 6.8 remains true modulo local knotting). For each $n \geq 1$ and $m \geq 2$, the abelianization of
\[
\frac{BF_{(n)}^m/BF_{(n+1)}^m}{KF_{(n)}^m/KF_{(n)}^m}
\]
has infinite rank; hence $(BF_{(n)}^m/BF_{(n+1)}^m)/(KF_{(n)}^m/KF_{(n)}^m)$ is an infinitely generated subgroup of $(F_{(n)}^m/F_{(n+1)}^m)/(KF_{(n)}^m/KF_{(n)}^m)$.

**Proof.** This follows from the proof of Theorem 6.8 once we show that $\rho_n$ vanishes for $(n)$-solvable string links with $n \geq 1$. To see this, let $L \in KF_{(n)}^m$ where $n \geq 1$. Since $L$ is $(n)$-solvable for $n \geq 1$, $\rho_0(L) = 0$. Since $L \in K(m)$, $L$ can be obtained from the trivial string link by tying local knots into the strings. That is, $L = L_m(\eta_m, K_m)$ where $L_i$ is defined inductively by: $L_0$ is the trivial link and $L_{i+1} = L_i(\eta_i, K_i)$ for some $\eta_i \in \pi_1(S^3 - L_i) - \pi_1(S^3 - L_i)^{(i)}$ and knot $K_i$. Hence by applying Proposition 5.8 multiple times we have $\rho_0(L) = \sum_{i=1}^m \rho_0(K_i) = \rho_0(L) = 0$. \qed

**Question 6.10.** Is $BF_{(n)}^m/BF_{(n,5)}^m$ (modulo local knotting for $m \geq 2$ and $n \geq 1$) infinitely generated for each $n \geq 0$ and $m \geq 1$? Is $BF_{(n,5)}^m/BF_{(n+1)}^m$ (modulo local knotting for $m \geq 2$ and $n \geq 1$) infinitely generated for each $n \geq 0$ and $m \geq 1$?
6.2. Grope Filtration of $C(m)$. There is another filtration of the link concordance group called the grope filtration, $G_n^m$, that is more geometric than the $(n)$-solvable filtration.

Definition 6.11. A grope is a special pair (2-complex, base circles). A grope has a height $n \in \mathbb{N}$. A grope of height 1 is precisely a compact, oriented surface $\Sigma$ with a non-empty boundary. A grope of height $(n+1)$ is defined inductively as follows: Let $\{\alpha_i, i = 1, \ldots, 2g\}$ be a standard symplectic basis of circles for $\Sigma$, the bottom stage of the grope. Then a grope of height $(n+1)$ is formed by attaching gropes of height $n$ (with a single boundary component, called the base circle) to each $\alpha_i$ along the base circle. A model of a grope can be constructed in $\mathbb{R}^4$ and thus has a regular neighborhood. Viewing $\mathbb{R}^3$ as $\mathbb{R}^3 \times \{0\} \hookrightarrow \mathbb{R}^3 \times [-1, 1]$, this model grope has a 4-dimensional regular neighborhood. When we say that a grope is embedded in a 4-dimensional manifold, we always mean that there is an embedding of the entire 4-dimensional regular neighborhood.

We say that $L \in C(m)$ is in $G_n^m$ if $\hat{L} \in S^3 = \partial(D^4)$ bounds an embedded grope of height $n$ in $D^4$. Note that if $L_1, L_2 \in C(m)$ and $\hat{L}_i$ for $i = 1, 2$ bounds an embedded grope of height $n$ in $D^4$ then $\hat{L}_1 \hat{L}_2$ bounds an embedded grope of height $n$ in $D^4$. Therefore, $G_n^m$ is a subgroup of $C(m)$. Moreover, since $L_1 L_2 L_1^{-1} \approx L_2$, $G_n^m$ is a normal subgroup of $C(m)$. We call

$$0 \subset \cdots \subset G_n^m \subset \cdots \subset G_1^m \subset C(m)$$

the grope filtration of $C(m)$. We define the grope filtration of the concordance group of boundary string links by $BG_n^m = G_n^m \cap B(m)$. For more about the grope filtration of a knot, see [11, 12, 13]. For more about gropes, see [16, 17].

The $(n)$-solvable and grope filtrations are related by the following theorem of T. Cochran, K. Orr, and P. Teichner.

Theorem 6.12 (Theorem 8.11 of [11]). If a link $L$ bounds a grope of height $(n+2)$ in $D^4$ then $L$ is $(n)$-solvable.

Hence for all $n \geq 0$ and $m \geq 1$, $G_{n+2}^m \subset F^m(n)$ (and hence $BG_{n+2}^m \subset BF^m(n)$). Note that Cochran-Orr-Teichner only state the above theorem for knots but their proof holds for links in $S^3$ as well. We show that certain quotients of the grope filtration are non-trivial.

Theorem 6.13. For each $n \geq 1$ and $m \geq 2$, the abelianization of $BG_n^m/BG_{n+2}^m$ has infinite rank; hence $BG_n^m/BG_{n+2}^m$ is an infinitely generated subgroup of $G_n^m/G_{n+2}^m$.

Proof. Let $\eta$ be a curve such that the homotopy class of $\eta$ is in $F(n) - F(n+1)$ where $F = \pi_1(S^3 - T)$ and $n \geq 0$. By Lemma 3.9 of [13], after changing $\eta$ by a homotopy in $S^3 - T$, we can assume that $\eta$ bounds a disk in $S^3$ and that $\eta$ bounds an embedded height $n$ grope in $S^3 - N(T)$. Consider the set $S_{\eta}$ as defined in [15] (but now using these specially chosen isotopy classes for $\eta$). We showed in the proof of Theorem 6.8 that $\rho_n(S_{\eta})$ is a $\mathbb{Z}$-linearly independent subset of $\mathbb{R}$. We will show that if $L \in S_{\eta}$ then $L$ bounds a grope of height $(n+1)$. Since $BG_{n+3}^m \subset BF^m(n+1)$, $\rho_n : BG_{n+1}^m/BG_{n+3}^m \to \mathbb{R}$ is a well defined homomorphism. This will complete the proof of the theorem.

Let $L \in S_{\eta}$ then $L = T(\eta, K)$ where $K$ is a knot. By Murakami and Nakanishi [28], $K$ can be obtained from the unknot by doing a sequence of delta moves. Hence,
in the language of Habiro [19], $K$ is related to the unknot by a finite sequence of simple $C_2$-moves and ambient isotopies. Therefore, by Theorem 3.17 of [19], $K$ is the result of clasper surgery on the unknot along $\bigsqcup_{i=1}^l C(T_i, r_i)$ where $(T_i, r_i)$ is a rooted symmetric tree of height 1 and the leaves are copies of the meridian of the unknot. Therefore, $L = T(\eta, K)$ is the result of clasper surgery on the trivial link $T$ along $\bigsqcup_{i=1}^l C(T_i, r_i)$ where $(T_i, r_i)$ is a rooted symmetric tree of height 1 and the leaves are copies of $\eta$. Since $\eta$ bounds an embedded height $n$ grope in $S^3 - N(T)$, by Corollary 3.14 of [13], $L$ bounds a height $(n + 1)$ grope in $D^4$.  

We remark that there are knots that are the result of a union of clasper surgeries on the unknot along rooted trees of height 2 and have non-zero $\rho_0$ (see for example Figure 3.6 of [13]). By the same argument that was used in the proof of Theorem 6.13 we can show that if you choose such a $K$ then $L = T(\eta, K)$ bounds a grope of height $n + 2$ for $n \geq 0$. As a result, we see that the groups $BG_{n+2}/BG_{n+3}$ are non-trivial for $n \geq 0$.

**Proposition 6.14.** For each $n \geq 2$ and $m \geq 2$, the rank of the abelianization of $BG_{n+1}/BG_{n+2}$ is at least 1; hence $G_{n+1}/G_{n+2}$ contains an infinite cyclic subgroup.

Just as in the case of the $(n)$-solvable filtration, Theorem 6.13 and Proposition 6.14 are true “modulo local knotting.” We formalize this below. Thus these results cannot be obtained using the results in [11, 12, 13]. For each $n \geq 0$, define $K_G^n = \Gamma^n \cap K(m)$. Then $K_G^{n+1}$ is a normal subgroup of $K_G^n$ and $K_G^n/K_G^m$ is a normal subgroup of $BG_{n+1}/BG_{n+2}$. The proof of the following corollary is similar to the proof of Corollary 6.13 so we will omit the proof.

**Corollary 6.15.** (1) For each $n \geq 3$ and $m \geq 2$, the abelianization of $BG_{n+1}/BG_{n+2}$ has infinite rank; hence $(BG_{n+1}/BG_{n+2})/(K_G^n/K_G^m)$ is an infinitely generated subgroup of $(G_{n+1}/G_{n+2})(K_G^n/K_G^m)$.

(2) For each $n \geq 3$ and $m \geq 2$, the rank of the abelianization of $(BG_{n+1}/BG_{n+2})(K_G^n/K_G^m)$ is at least 1; hence $(G_{n+1}/G_{n+2})(K_G^n/K_G^m)$ contains an infinite cyclic subgroup.

**7. Applications to Boundary Link Concordance**

We point out some applications of our work to the study of boundary link concordance and to the abstract determination of certain $\Gamma$-groups and relative $L$-groups that have been previously studied by Cappell-Shaneson and LeDimet in the context of the classification of links up to concordance (sometimes called cobordism).

Recall that boundary links are amenable to classification because each component bounds a disjoint Seifert surface (alternatively because the fundamental groups of their exteriors admit epimorphisms to the free group). In fact it was originally hoped that every odd-dimensional link was concordant to a boundary link, so the classification of link concordance would have been reduced to the case of boundary links. Despite the collapse of this hope [10], boundary links remain an important case for study.
S. Cappell and J. Shaneson first considered pairs \((L, \theta)\) called \textbf{F-links} where \(L\) is an \(m\)-component boundary link and \(\theta\) is a fixed map \(\pi_1(S^3 \setminus L) \to F\) that is a splitting map for a meridional map. They defined a suitable concordance relation, called \textbf{F-concordance}, which entailed an ordinary link concordance between \(L_0\) and \(L_1\) but required that the fundamental group of the exterior of the concordance admit a map to \(F\) extending \(\theta_0\) and \(\theta_1\). See [1] for details. Let the \(m\)-component \(F\)-concordance classes of \((n\text{-dimensional}) F\)-links in \(S^{n+2}\) be denoted by \(\text{CF}(n,m)\). This is an abelian group if \(n > 1\), or if \(n = m = 1\) in which case it is equal to the classical knot concordance group. The boundary concordance group of boundary links, \(\mathcal{B}(n,m)\), is obtained by dividing out by the action of \(\text{Aut}_0(F)\), the group of generator-conjugating automorphisms of the free group, which eliminates the dependence on choice of \(\theta\). This classification (for \(n > 1\)) was later accomplished by K. Ko [23] and W. Mio [27] in terms of Seifert matrices and Seifert forms. More recently, D. Sheiham completed a more explicit classification in terms of signatures associated to quivers [30].

For a link \(L\) in \(S^{n+2}\) (with \(n > 1\)), define \(M_L\) to be the \((n+2)\)-dimensional manifold obtained by doing surgery on \(S^{n+2}\) along the components of \(L\) with the unique normal framing. For each link \(L\) in \(S^{n+2}\) where \(n \equiv 1 \mod 4\) with \(n > 1\), and each \(k \geq 0\), we define \(\rho_k(L) = \rho_k(M_L)\). It is then relatively straightforward (see Proposition 7.1) to show that the \(\rho\)-invariants considered herein give a rich source of invariants of \(\text{CF}(n,m)\) \((n \equiv 1 \mod 4\) and \(n > 1\)). One should compare [24] where \(\rho\)-invariants associated to representations into finite unitary groups are used in an analogous fashion.

**Proposition 7.1.** For any \(k \geq 0\), \(n \equiv 1 \mod 4\) with \(n > 1\), the invariant \(\rho_k\) induces a homomorphism \(\tilde{\rho}_k : \text{CF}(n,m) \to \mathbb{R}\) that factors through \(\mathcal{B}(n,m)\).

**Proof.** The situation can be summarized in the following diagram where \(\mathcal{B}(n,m)\) is the group of concordance classes of \(m\) component, \(n\)-dimensional boundary disk links in \(D^{n+2}\) (sometimes called boundary string links if \(n = 1\)); where \(\psi\) is the natural lift defined by Levine [24] Proposition 2.1] (only for \(n > 1\)); and \(I\) is the natural forgetful map.

\[
\begin{array}{c}
\text{CF}(n,m) \xrightarrow{\psi} \mathcal{B}(n,m) = \text{CF}(n,m)/\text{Aut}_0(F) \xrightarrow{I} \{\text{Boundary Links}\} \xrightarrow{\rho_k} \mathbb{R} \\
\end{array}
\]

Since \(\rho_k\) is an invariant of concordance of links, the horizontal composition, denoted \(\tilde{\rho}_k\), exists. \(\square\)

The group \(\text{CF}(n,m)\), \(n > 1\), has been classified by the aforementioned authors in terms of \(\Gamma\)-groups, Seifert matrices and quiver signatures. The biggest question in this field is whether or not \(I\) is injective. Our results offer further evidence that it is injective by showing that many powerful signature invariants (the \(\rho_k\)) of boundary links, that a priori are only invariants of \(F\)-concordance, are actually ordinary concordance invariants.

**Question 7.2.** How many of Sheiham’s quiver-signatures are captured by information from \(\rho_k\)?
If the \( \{ \rho_k \} \) were strong enough to detect all of Sheiham’s signatures then it would follow that the kernel of \( I \) is torsion.

Since Cappell and Shaneson have essentially identified \( CF(n,m) \), \( n > 1 \), with the quotient of a certain gamma group \( \Gamma_{n+3}(ZF \to Z) \) (relative \( L \)-group) modulo the image of \( L_{n+3}(ZF) \) [1] Theorem 2, Theorem 4.1] we have the following result.

**Proposition 7.3.** For each \( n \equiv 1 \mod 4 \) with \( n > 1 \), and each \( k \geq 0 \), there is an induced homomorphism

\[
\tilde{\rho}_k : \tilde{\Gamma}_{n+3}(ZF \to Z)/\text{Aut } F \to \mathbb{R}.
\]

Using the techniques of this paper we can also show that each \( \tilde{\rho}_k \) extends to the corresponding \( \Gamma \)-groups of the algebraic closure \( \hat{F} \) of the free group, in terms of which LeDimet has successfully “classified” the higher-dimensional concordance group of disk links [15].
