ABSTRACT: We consider conformal and ’t Hooft anomalies in six-dimensional $\mathcal{N} = (1, 0)$ superconformal field theories, focusing on those conformal anomalies that determine the two- and three-point functions of conserved flavor and SU(2)$_R$ currents, as well as stress tensors. By analyzing these correlators in superspace, we explain why the number of independent conformal anomalies is reduced in supersymmetric theories. For instance, non-supersymmetric CFTs in six dimensions have three independent conformal $c$-anomalies, which determine the stress-tensor two- and three-point functions, but in superconformal theories the three $c$-anomalies are subject to a linear constraint. We also describe anomaly multiplet relations, which express the conformal anomalies of a superconformal theory in terms of its ’t Hooft anomalies. Following earlier work on the conformal $a$-anomaly, we argue for these relations by considering the supersymmetric dilaton effective action on the tensor branch of such a theory. We illustrate the utility of these anomaly multiplet relations by presenting exact results for conformal anomalies, and hence current and stress-tensor correlators, in several interacting examples.

ArXiv ePrint: 1912.13475
1 Introduction

1.1 Conformal anomalies

The hallmark of conformal invariance in local quantum field theory is the existence of a traceless stress tensor $T_{\mu\nu}$. However, when a conformal field theory (CFT) in even spacetime dimension $d$ is coupled to background fields, such as a gauge field sourcing a conserved current $J_{\mu}$, or a metric sourcing $T_{\mu\nu}$, quantum anomalies can lead to a non-vanishing trace. In this case, the one-point function $\langle T_{\mu}^\mu \rangle$ is a quantity of scaling dimension $d$ constructed from the background field strengths. The structure of these expressions in the background fields is universal and can be fixed using symmetries, while the coefficients of the allowed terms are theory-dependent conformal anomalies.

Standard conformal anomalies can also be interpreted directly in terms of the underlying CFT, without background fields. Then $T_{\mu}^\mu$ vanishes as an operator, and hence has trivial correlation functions at separated points, but it has non-vanishing contact terms.
dictated by the anomalies. Such contact terms are ultimately related to stress-tensor correlators at separated points, and hence they provide meaningful and useful information about the CFT.

In this paper we focus on conformal anomalies of CFTs in $d = 6$ dimensions. Coupling such a theory to a curved background metric leads to four possible anomalies, whose coefficients are conventionally called $a$ and $c_1, c_2, c_3$ [1–4],

$$\langle T_\mu^\mu \rangle \supset a E + c_1 I_1 + c_2 I_2 + c_3 I_3 .$$

(1.1)

Here $E$ is the Euler density in six dimensions, which is given in terms of the Riemann curvature two-form $R^{ab}$ as

$$E = \varepsilon_{a_1 a_2 a_3 a_4 a_5 a_6} R^{a_1 a_2} R^{a_3 a_4} R^{a_5 a_6} ,$$

(1.2)

while the $I_i$ are expressions constructed out of the Weyl curvature tensor (for precise expressions see e.g. [4]),

$$I_1 \sim W_\mu^\rho \sigma W_\rho^\chi \psi \chi W^{\mu \nu} , \quad I_2 \sim W_{\mu \nu \rho \sigma} W^{\rho \sigma} \chi \psi W^{\mu \nu} , \quad I_3 \sim W_{\mu \nu \rho \sigma} \nabla^2 W^{\mu \nu \rho \sigma} + \cdots .$$

(1.3)

In terms of correlation functions at separated points, the coefficient $c_3$ determines the two-point function of $T_{\mu \nu}$, while $c_1, c_2, c_3$ fix the three-point function of $T_{\mu \nu}$. The anomaly coefficient $a$ first arises in a four-point function of stress tensors. We fix a convenient convention for SCFTs in $d = 6$ such that a single, free $\mathcal{N} = (2,0)$ tensor multiplet has $a = c_1 = c_2 = c_3 = 1$. Table 1 lists the conformal anomalies of some six-dimensional CFTs in these conventions.

In CFTs with continuous flavor symmetries, there are additional conformal anomalies. To lighten notation, we focus on a single factor $G_F$ of the full flavor symmetry; here $G_F$ could be either U(1) or simple. In the presence of background gauge fields (with field strength $F_{\mu \nu}$) that source the associated conserved flavor current $J_F^\lambda$, these flavor conformal anomalies take the following form,

$$\langle T_\mu^\mu \rangle \supset -\frac{\tau_1^F}{3} \text{Tr}(D_\mu F^{\mu \lambda} D^\nu F_{\nu \lambda}) - \frac{\tau_2^F}{4} W_{\mu \nu \rho \lambda} \text{Tr}(F^{\mu \nu} F^{\rho \lambda}) + \frac{\rho^F}{3} \text{Tr}(F_{\mu \nu} F_\lambda F^\lambda_{\nu \lambda}) + \cdots .$$

(1.4)

Here we omitted several additional terms that are fixed by conformal symmetry; we also dropped total derivative terms. We conclude that every U(1) or simple factor $G_F$ of the flavor symmetry gives rise to three conformal anomaly coefficients: $\tau_1^F, \tau_2^F$, and $\rho^F$. Note that the anomaly controlled by $\rho^F$, which is cubic in the field strength $F_{\mu \nu}$, is proportional to the structure constants $f^{abc}$ of $G_F$ and hence vanishes for abelian flavor symmetries.

As we will review below, these conformal anomalies encode basic data about correlation functions of conserved currents in the CFT at separated points and in the absence of background fields. Specifically, $\tau_1^F$ determines the two-point function $\langle J^F J^F \rangle$, while $\tau_1^F$, $\tau_2^F$ determine the three-point function $\langle T J^F J^F \rangle$, and $\tau_1^F$, $\rho^F$ determine the three-point function $\langle J^F J^F J^F \rangle$. We see that conformal anomalies completely determine all two- and three-point functions of flavor currents and the stress tensor.
Table 1. Conformal anomalies of some \( d = 6 \) CFTs. The first three lines are the minimal free field theories in six dimensions. The two subsequent lines are the free \( \mathcal{N} = (1, 0) \) SCFTs. The final line summarizes the interacting \( \mathcal{N} = (2, 0) \) SCFTs. These are labelled by an ADE Lie algebra \( \mathfrak{g} \), and their conformal anomalies are determined in terms of the rank \( r_\mathfrak{g} \), the dimension \( d_\mathfrak{g} \), and the dual coxeter number \( h^\vee_\mathfrak{g} \) of \( \mathfrak{g} \). The large-\( N \) behavior of these conformal anomalies was established in [5]. The exact formula for \( a \) was computed in [6]. The exact formula for the \( c \)-anomalies of \( \mathcal{N} = (2, 0) \) theories was conjectured in [7] and derived in [8].

| Theory                        | \( a \) | \( c_1 \) | \( c_2 \) | \( c_3 \) |
|-------------------------------|---------|---------|---------|---------|
| Scalar                        | \( \frac{1}{431} \) | \( \frac{1}{180} \) | \( -\frac{1}{252} \) | \( \frac{1}{70} \) |
| Weyl Fermion                  | \( \frac{191}{4110} \) | \( \frac{4}{45} \) | \( \frac{4}{105} \) | \( \frac{1}{7} \) |
| Chiral Two-Form               | \( \frac{221}{245} \) | \( \frac{143}{180} \) | \( \frac{1189}{1260} \) | \( \frac{9}{13} \) |
| (1,0) Hypermultiplet          | \( \frac{11}{210} \) | \( \frac{1}{9} \) | \( \frac{1}{35} \) | \( \frac{1}{5} \) |
| (1,0) Tensor multiplet        | \( \frac{199}{210} \) | \( \frac{8}{9} \) | \( \frac{44}{35} \) | \( \frac{4}{5} \) |
| (2,0) Theory with algebra \( \mathfrak{g} \) | \( \frac{16 h^\vee_\mathfrak{g} d_\mathfrak{g}}{r_\mathfrak{g}} + r_\mathfrak{g} \) | \( 4 h^\vee_\mathfrak{g} d_\mathfrak{g} + r_\mathfrak{g} \) | \( 4 h^\vee_\mathfrak{g} d_\mathfrak{g} + r_\mathfrak{g} \) | \( 4 h^\vee_\mathfrak{g} d_\mathfrak{g} + r_\mathfrak{g} \) |

1.2 Supersymmetry constraints on conformal anomalies

In general, non-supersymmetric CFTs, the three \( c_i \) anomalies are independent. Below we will prove that \( \mathcal{N} = (1, 0) \) SCFTs only have two independent \( c_i \) anomalies. In such theories, the three \( c_i \) coefficients are related by a universal, linear relation dictated by supersymmetry,

\[
c_1 = \frac{1}{2} \left( c_2 + c_3 \right).
\]

As we will see, one consequence of this relation is that the two distinct unitary \( \mathcal{N} = (1, 0) \) free field theories, i.e. the free hypermultiplet and the free tensor multiplet, span the space of stress-tensor supermultiplet three-point functions.

The relation (1.5) was conjectured in [9], where it was noted that it is satisfied by all free-field and holographic examples, and that it is analogous to a known relation obeyed by four-dimensional SCFTs in the context of conformal collider physics [10] (see below). A linear relation between the \( c_i \) anomalies is also suggested by the more recent observation [11] that minimal conformal supergravity in \( d = 6 \) appears to only admit two independent candidate invariants that can supersymmetrize the \( I_i \) invariants in (1.1) and (1.3).
In section 3 we establish (1.5) via a superspace analysis. We show that the superspace three-point function of stress-tensor supermultiplets $\mathcal{T}(x_i, \theta_i)$ takes the general form

$$
\langle \mathcal{T}(x_1, \theta_1) \mathcal{T}(x_2, \theta_2) \mathcal{T}(x_3, \theta_3) \rangle \sim H_{TTT}(Z) = C_{1,2,3}^{TTT} \left( \frac{1}{X^4} + \frac{X^2}{X^8} + \frac{X^4}{X^8} + \frac{X^6}{X^8} \right),
$$

which depends on three real constants $C_{1,2,3}^{TTT}$ that are linearly related to the $c_i$ anomalies. (Here $Z = (X, \Theta)$ is a superspace variable that is constructed using the three superspace coordinates $(x_i, \theta_i)$.) We then argue that the conservation equation obeyed by the stress-tensor multiplet imposes one linear constraint on the coefficients $C_{1,2,3}^{TTT}$, which in turn leads to the relation (1.5) among the $c_i$.

We also use superspace to analyze those supermultiplet three-point functions that can be obtained from (1.6) by replacing one, two, or all three stress-tensor multiplets by conserved flavor-current multiplets. In every case supersymmetry imposes one additional linear relation on the coefficients of the corresponding non-supersymmetric correlators. It follows that some of the conformal anomalies related to flavor symmetries, which were defined in (1.4), vanish in all $\mathcal{N} = (1, 0)$ SCFTs,

$$\tau_F^2 = \rho_F = 0.$$  \hspace{1cm} (1.7)

To streamline the notation, we will often write

$$\tau_F^1 \equiv \tau_F$$

for the unique non-vanishing conformal anomaly coefficient associated with the flavor symmetry $G_F$. The relations above imply that $\tau_F$ governs both the $\langle J^F J^F \rangle$ two-point function, as well as the $\langle T^F J^F \rangle$ and $\langle J^F J^F J^F \rangle$ three-point functions.

In terms of conformal collider observables [10], the fact that $\tau_F^2 = 0$ implies that the energy flux $\langle E(n) \rangle$ in a state created by the flavor current is independent of its polarization. Similarly, the fact that $\rho_F = 0$ implies that the charge flux $\langle Q(n) \rangle$ in such a state is also independent of the polarization. These properties of flavor currents in six-dimensional SCFTs are direct analogues of relations that hold for SCFTs in four dimensions [10].

Every $\mathcal{N} = (1, 0)$ SCFT has an $SU(2)_R$ symmetry. The associated conserved current $J^R_\mu$ resides in the stress-tensor supermultiplet, and consequently the conformal anomaly coefficients $\tau_1^R$ and $\rho^R$ it gives rise to need not satisfy the relations (1.7) that hold for flavor currents. Adapting the arguments outlined above to this case, we find that the conformal anomaly coefficients associated with the $SU(2)_R$ symmetry can be expressed using two linearly independent $c_i$ anomaly coefficients (with the third one given by (1.5)),

$$
\tau_1^R = c_3, \quad \tau_2^R = \frac{1}{2} (c_3 - c_1), \quad \rho^R = \frac{3}{2} (c_1 - c_3).
$$

(1.9)

Let us consider the special case of $\mathcal{N} = (2, 0)$ theories, which have an $Sp(4)_R$ symmetry. When viewed as $\mathcal{N} = (1, 0)$ theories, it is natural to focus on the maximal subgroup $SU(2)_R \times SU(2)_F \subset Sp(4)_R$. Here $SU(2)_R$ and $SU(2)_F$ are $R$- and flavor symmetries.
that are distinguished by the choice of $\mathcal{N} = (1, 0)$ subalgebra, but they are exchanged
by a Weyl reflection inside the full $\text{Sp}(4)_R$ symmetry. It follows that the vanishing con-
ditions (1.7) that hold for the $\text{SU}(2)_F$ symmetry must also apply to $\text{SU}(2)_R \subset \text{Sp}(4)_R$,
i.e. $\tau^2 = \rho^R = 0$. Comparing with (1.9) (and using (1.5)), we conclude that the $c_i$ anomali-
ies of all $\mathcal{N} = (2, 0)$ theories necessarily coincide, in agreement with the explicit formulas
in table 1.

1.3 Anomaly multiplets

So far we have discussed conformal anomalies (i.e. ’t Hooft anomalies for conformal symme-
try), which arose from various conserved currents such as the stress tensor or a flavor cur-
rent. These currents may themselves have more conventional ’t Hooft anomalies, which lead
to violations of current conservation in the presence of background fields. Such anomalies
are conveniently summarized by an anomaly 8-form, from which the anomalous transfor-
mation of the effective action follows via the standard descent procedure (see e.g. [14] for a
detailed recent discussion with references). For instance, ’t Hooft anomalies for the $\text{SU}(2)_R$
symmetry or dieomorphisms are characterized by the following anomaly polynomial,

$$
I_8 \supset \frac{1}{4!} \left( \alpha c_2(R)^2 + \beta c_2(R)p_1(T) + \gamma p_1(T)^2 + \delta p_2(T) \right).
$$

The corresponding ’t Hooft anomaly coefficients $\alpha, \beta, \gamma, \delta$ are universal and independent
observables in any six-dimensional $\mathcal{N} = (1, 0)$ SCFT. They are often exactly calculable,
e.g. via string constructions and anomaly inflow arguments [15, 16] or by analyzing RG
flows [17-20]. We enumerate these anomaly coefficients for several $\mathcal{N} = (1, 0)$ theories in
table 2.

It is an important and general fact that supersymmetry relates conformal anomalies
and ’t Hooft anomalies. This means that the typically challenging and delicate conformal
anomalies can be analyzed using the more accessible and robust ’t Hooft anomalies. In the
case of $d = 4$ SCFTs, such relations were established in [23] by analyzing the anomalous
stress-tensor supermultiplet of the SCFT in the presence of background supergravity fields — an object often referred to as the anomaly multiplet. In [24] we derived an anomaly mul-
tiplet relation between the conformal anomaly $a$ and ’t Hooft anomaly coefficients in (1.10),

$$
a = \frac{16}{7} (\alpha - \beta + \gamma) + \frac{6}{7} \delta.
$$

Rather than analyzing the anomalous stress-tensor supermultiplet in $d = 6$ SCFTs, this
relation was derived by studying the dilaton effective action on the tensor branch of the
SCFT — a technique we will also utilize in this paper. A consequence of this derivation

---

2 This agrees with a conjecture of [13] that was motivated by free-field and holographic reasoning.

3 Here $c_i(R)$ denotes the Chern class of degree $2i$ for the $\text{SU}(2)_R$ background gauge bundle, while $p_i(T)$
denotes the Pontryagin class of degree $4i$ for the tangent bundle.

4 A direct analysis of anomalous stress-tensor multiplets is more challenging in $d = 6$ than in $d = 4$.
For instance, non-conformal stress-tensor multiplets (of which the anomaly multiplet is a special case)
and the associated supergravity theories have been thoroughly analyzed in $d = 4$ (see e.g. [25, 26] and
references therein), while their $d = 6$ counterparts are not nearly as well studied. Moreover, a direct
was a proof of the \( a \)-theorem for RG flows from the SCFT onto its tensor branch.\(^5\) The behavior of \( a \) under Higgs branch RG flows was subsequently explored in [30], and the anomaly multiplet relation (1.11) has been verified holographically in [31].

In this paper, we likewise establish anomaly multiplet relations for the \( c_1 \) conformal anomalies in (1.1), by expressing them in terms of the ’t Hooft anomaly coefficients \( \alpha, \beta, \gamma, \delta \) in (1.10) via the following formulas,

\[
c_1 = 4\alpha - \frac{14}{3} \beta + \frac{16}{3} \gamma + \frac{8}{3} \delta, \quad c_2 = 4\alpha - \frac{10}{3} \beta + \frac{8}{3} \gamma + \frac{10}{3} \delta, \quad c_3 = 4\alpha - 6\beta + 8\gamma + 2\delta . \tag{1.12}
\]

Note that these formulas are compatible with the universal linear relation \( c_1 = \frac{1}{2} (c_2 + c_3) \) in (1.5), even though \( \alpha, \beta, \gamma, \delta \) are independent.

In theories with flavor symmetries, there are additional ’t Hooft anomaly coefficients that are visible in the presence of background flavor gauge fields. As above, we consider a single abelian or simple factor \( G_F \) of the full flavor symmetry, and we focus on the mixed anomalies of \( G_F \) with the \( SU(2)_R \) symmetry or diffeomorphisms,

\[
\mathcal{I}_8 \supset \frac{1}{4!} (\alpha_{F^2R^3} c_2(F) c_2(R) + \alpha_{F^2T^2} c_2(F) p_1(T)) . \tag{1.13}
\]

We will argue that the ’t Hooft anomaly coefficients \( \alpha_{F^2R^3} \) and \( \alpha_{F^2T^2} \) determine the conformal anomaly coefficient \( \tau_F \) in (1.8) as follows,

\[
\tau_F = 2\alpha_{F^2T^2} - 2\alpha_{F^2R^2} . \tag{1.14}
\]

\(^5\)It was shown in [27–29] that the only supersymmetric RG flows in six dimensions that start at a SCFT fixed point are flows onto the moduli space of vacua of that SCFT.

\[
\text{Table 2. } SU(2)_R \text{ and diffeomorphism } \text{’t Hooft anomaly coefficients of some } \mathcal{N} = (1,0) \text{ theories. Note that the free vector multiplet is not conformal, but nevertheless enjoys an } SU(2)_R \text{ symmetry. The } \mathcal{N} = (2,0) \text{ anomalies for } g = su(N) \text{ were first computed in [15]. The general formulas for any ADE Lie algebra } g \text{ were conjectured in [21] and verified in [6, 17, 22].}
\]

\[

\]

\[
\text{The } \mathcal{N} = (2,0) \text{ behavior of } a \text{ under Higgs branch RG } \text{flows was subsequently explored in [30], and the anomaly multiplet relation (1.11) has been verified holographically in [31].}
\]
The formulas (1.12) have already appeared in the recent literature [32, 33]. There linear relations between the \( c_i \) conformal anomalies and the ‘t Hooft anomaly coefficients \( \alpha, \beta, \gamma, \delta \) were postulated, and the unknown coefficients in these relations were fixed by considering examples. This is complicated by the fact that each anomaly multiplet relation is specified by four coefficients, while there are only three independent classes of unitary SCFTs for which all pertinent anomalies are reliably known (the free hyper- and tensor multiplets, and the \( \mathcal{N} = (2,0) \) theories). To circumvent this problem, the authors of [32, 33] considered a non-unitary but superconformal free field theory constructed from an abelian vector multiplet with a higher-derivative kinetic term as a fourth data point. This theory had previously been shown to satisfy the anomaly multiplet relation (1.11) for the \( a \) conformal anomaly [34].

In section 4, we will instead follow [24] and argue for the anomaly multiplet relations (1.12) and (1.14) by studying conformal and ‘t Hooft anomaly matching along RG flows from an SCFT onto its tensor branch. As in [24], our main tool will be the super-symmetric dilaton effective action on the tensor branch.

1.4 Application to the small \( E_8 \) instanton SCFTs

The anomaly multiplet relations (1.12) and (1.14) have a wide variety of applications. Many \( \mathcal{N} = (1,0) \) SCFTs in six dimensions have been constructed in string theory, starting with [35, 36] and generalizations in [37–41], recently culminating in a systematic analysis using F-theory [42–44]. Such theories have also been explored using holography [45–47]. None of these \( \mathcal{N} = (1,0) \) SCFTs possess a known Lagrangian description. They are essentially isolated (because they do not admit any supersymmetry-preserving relevant or marginal deformations [27–29]) and strongly coupled (see for instance [48]). Nevertheless, as we illustrate in section 5, the conformal anomalies of these strongly-coupled SCFTs can often be determined using anomaly multiplet relations. For instance, in the \( \mathcal{N} = (1,0) \) SCFT described by \( N \) small \( E_8 \) instantons in string theory [37] we can use (1.14) to compute the two-point function coefficient \( \tau_{E_8} \) of the \( E_8 \) flavor currents,

\[
\tau_{E_8} = 24N^2 + 36N.
\] (1.15)

This formula has already appeared in [49], where it was found to agree with bootstrap results.

2 Current and stress-tensor two- and three-point functions

In this section we review results from [50, 51] about two- and three-point functions of conserved flavor currents \( J_\mu^a \) associated with a global flavor symmetry \( G_F \), and the stress-tensor \( T_{\mu\nu} \). We explain how these correlation functions are related to conformal anomaly coefficients, completing various discussions in the existing literature. In this section we consider general CFTs, without assuming supersymmetry. For each two- and three-point current correlator, we first present results for a general spacetime dimension \( d \) before specializing to \( d = 6 \). As above, we assume that the flavor symmetry \( G_F \) is abelian or simple. Flavor Lie algebra indices will be denoted by \( a, b, c, \ldots \).
Two-point functions are completely determined by conformal symmetry, up to an overall coefficient. For flavor currents and the stress tensor we have

\[ h J^a(x) J^b(0) = \frac{C_F \delta^{ab}}{x^{2(d-1)}} I_{\mu\nu}(x), \quad h T_{\mu\nu}(x) T_{\rho\sigma}(0) = \frac{C_T}{x^{2d}} I_{\mu\nu,\rho\sigma}(x), \quad (2.1) \]

where

\[ I_{\mu\nu}(x) = \delta_{\mu\nu} - \frac{2 x_{\mu} x_{\nu}}{x^2}, \quad I_{\mu\nu,\rho\sigma} = \frac{1}{2} (I_{\mu\nu,\rho\sigma} + I_{\mu\rho,\nu\sigma}) - \frac{1}{d} \delta_{\mu\nu} \delta_{\rho\sigma}. \quad (2.2) \]

In \( d = 6 \) dimensions, the two-point function coefficient \( C_T \) is proportional to the conformal anomaly coefficient \( c_3 \) in \((1.1)\). To determine the proportionality constant, it suffices to compare them for free-field CFTs. For a theory with \( n_\phi \) free scalar fields and \( n_\psi \) free fermion fields (with \( \text{dim}(\psi) \) complex spinor components), it was shown in \([50]\) that

\[ C_T = n_\phi \frac{d}{d-1} \frac{1}{S_d^2} + n_\psi \frac{d}{2} \frac{\text{dim}(\psi)}{S_d^2} \rightarrow \frac{6}{5\pi^6} (n_\phi + 10n_\psi). \quad (2.3) \]

Here \( S_d = 2\pi^{d/2}/\Gamma(d/2) \); in the last expression we have set \( d = 6 \) and taken \( n_\psi \) to be the number of chiral fermions, with \( \text{dim}(\psi) = 4 \) complex components. We can now compare with our normalization for \( c_3 \) in table 1 to conclude that

\[ c_3 \equiv \frac{\pi^6}{84} C_T. \quad (2.4) \]

Similarly, the flavor-current two-point function coefficient \( C_F \) is proportional to the conformal anomaly coefficient \( \tau_F^1 \) in \((1.4)\). We will choose a convention for the proportionality factor that is convenient for six-dimensional SCFTs. It was shown in \([50]\) that in free scalar theories, with flavor current \( J^a_\mu = \phi t^a_\mu \partial_\mu \phi \) (here \( t^a_\mu \) is real and antisymmetric), and in free fermion theories, with flavor current \( J^a_\mu = i t^a_\mu \gamma_\mu \psi \) (here \( t^a_\psi \) is complex and antihermitian) the coefficient \( C_F \) is given by

\[ C_F = \frac{T_\phi}{2} \frac{1}{(d-2)S_d^2} + \frac{T_\psi}{2} \frac{\text{dim}(\psi)}{S_d^2} \rightarrow \frac{1}{8\pi^6} (T_\phi + 16 T_\psi). \quad (2.5) \]

The first expression is valid for general \( d \), while we have set \( d = 6 \) in the second expression. The coefficients depend on the quadratic indices for the representations of the bosons or fermions, \( \text{tr}(t^a_{\phi,\psi} t^b_{\phi,\psi}) = -\frac{1}{2} T_{\phi,\psi} \delta^{ab} \). We choose our normalization convention for \( \tau_F^1 \) such that the \( \text{Sp}(4)_R \) symmetry that acts on a free \( \mathcal{N} = (2,0) \) tensor multiplet has \( \tau_{1,\text{Sp}(4)_R}^1 = 1 \). This is equivalent to the statement that the \( \text{SU}(2)_F \) flavor symmetry that acts on a single, free \( \mathcal{N} = (1,0) \) hypermultiplet has \( \tau_F^1 = 1 \). Thinking of such a free hypermultiplet as a half-hyper that transforms as an \( \mathcal{N} = (2,0) \) doublet, we conclude that it has \( T_\phi = 2, T_\psi = \frac{1}{2} \), so that

\[ \tau_F^1 \equiv \frac{4\pi^6}{5} C_F. \quad (2.6) \]

For generic \( d \), it was shown in \([50, 51]\) that the flavor-current three-point function \( \langle J^a_\mu(x) J^b_\nu(y) J^c_\lambda(z) \rangle \) is fully determined by conformal symmetry and conservation laws, up
to two coefficients $A_{FFF}$ and $B_{FFF}$,

$$\langle J^a_{\mu}(x)J^b_{\nu}(y)J^c_{\lambda}(z) \rangle = f^{abc} I_{\nu\sigma}(x-y)I_{\lambda\rho}(x-z)I_{\sigma\beta}(X) \frac{t_{\mu\beta}(X)}{(x-y)^{d-2}(x-z)^{d-2}(y-z)^{d-2}} ,$$

where $f^{abc}$ are the structure constants and

$$X_\mu = \frac{(x-y)_\mu}{(x-y)^2} - \frac{(x-z)_\mu}{(x-z)^2} , \quad t_{\mu\nu\lambda}(X) = A_{FFF} X_\mu X_\nu X_\lambda + B_{FFF}(X_\mu \delta_{\nu\lambda} + X_\nu \delta_{\mu\lambda} - X_\lambda \delta_{\mu\nu}) .$$

A Ward identity implies that $[50, 51]$

$$C_F = S_d \left(\frac{1}{d} A_{FFF} + B_{FFF}\right) \rightarrow \frac{\pi^3}{6} \left(\frac{A_{FFF}}{6} + B_{FFF}\right) .$$

Thus the $\langle JJJ \rangle$ three-point function introduces one additional, theory-dependent constant beyond the $\langle JJ \rangle$ two-point function coefficient $C_F$.

The free-field values of the coefficients $A_{FFF}$ and $B_{FFF}$ were computed in $[50]$

$$A_{FFF} = \frac{d T_\phi}{4(d-2)S_d^3} \rightarrow \frac{3}{8\pi^9} T_\phi ,$$
$$B_{FFF} = \frac{T_\phi}{4(d-2)S_d^3} + \frac{T_{\psi} \text{dim}(\psi)}{2S_d^3} \rightarrow \frac{1}{\pi^9} \left(\frac{T_\phi}{16} + 2T_\psi\right) .$$

Instead of using $A_{FFF}, B_{FFF}$ to parameterize the $\langle JJJ \rangle$ three-point function, we can also express it in terms of free scalar or fermion correlators,

$$\langle J^a_{\mu}(x)J^b_{\nu}(y)J^c_{\lambda}(z) \rangle = n^{FFF}_\phi \langle J^a_{\mu}(x)J^b_{\nu}(y)J^c_{\lambda}(z) \rangle_\phi + n^{FFF}_\psi \langle J^a_{\mu}(x)J^b_{\nu}(y)J^c_{\lambda}(z) \rangle_\psi .$$

The two coefficients $n^{FFF}_\phi$ and $n^{FFF}_\psi$ are linearly related to $A_{FFF}$ and $B_{FFF}$. The exact relation can be extracted from the free-field results summarized above.

The stress-tensor three-point function $\langle T_{\mu\nu}(x)T_{\rho\sigma}(y)T_{\nu\lambda}(z) \rangle$ is also determined by conformal symmetry and conservation laws up to three coefficients $[50, 51]$. A Ward identity relates one linear combination of these three coefficients to the two-point function coefficient $C_T$. In $d = 6$ dimensions, the three stress-tensor three-point function coefficients are linearly related to the three conformal anomalies $c_1, c_2, c_3$ in (1.1). We can span the three structures using the stress-tensor three-point functions of free fields: a free scalar $\phi$, a free Weyl fermion $\psi$, and a free, chiral two-form $B$ (with self-dual three-form field strength $H$), see $[52]$ for details,

$$\langle TTT \rangle = n^{TTT}_\phi \langle TTT \rangle_\phi + n^{TTT}_\psi \langle TTT \rangle_\psi + n^{TTT}_B \langle TTT \rangle_B .$$

In a free theory, the coefficients $n^{TTT}_{\phi,\psi,B}$ coincide with the number $n_\phi, n_\psi, n_B$ of free scalars, Weyl fermions, or chiral two-forms, but in an interacting CFT they are defined by (2.12). In general, these coefficients are constrained by unitarity and conformal collider inequalities.
Comparing to the known free-field conformal anomalies (see [52, 53] and table 1) we conclude that
\begin{align}
c_1 &= n^{TTT}_\phi + 16 n^{TTT}_\psi + 143 n^{TTT}_B, \\
c_2 &= -5 n^{TTT}_\phi + 48 n^{TTT}_\psi + 1189 n^{TTT}_B, \\
c_3 &= n^{TTT}_\phi + 10 n^{TTT}_\psi + 45 n^{TTT}_B.
\end{align}
(2.13)

We now consider the three-point function \(\langle TJJ \rangle\) of one stress tensor and two flavor currents, which was also analyzed in [50, 51] and shown to be determined by two coefficients. One linear combination of these coefficients is proportional to the \(\langle JJ \rangle\) two-point function coefficient \(C_F\) (or equivalently to \(\tau^F_1\), see (2.6)) thanks to a Ward identity, while the remaining independent structure constant can be thought of as the OPE coefficient of the stress tensor in the fusion of two flavor currents.

In the notation of [50, 51] (see for instance the discussion around equation (3.14) of [50]), the two coefficients that determine the \(\langle TJJ \rangle\) three-point function are called \(c_{TFF}\) and \(e_{TFF}\). Their free-field values can be found in equation (5.10) of [50]; setting \(d \to 6\) and \(\dim(\psi) = 4\) in these formulas, we find that
\begin{align}
\pi^0_{c_{TFF}} &= \frac{3}{5} T_\phi + 12 T_\psi, \\
\pi^0_{e_{TFF}} &= \frac{3}{20} T_\phi.
\end{align}
(2.14)

It follows that the two independent structures in the \(\langle TJJ \rangle\) three-point function are spanned by free field theories in which the flavor current only arises from charged scalars or fermions,
\begin{equation}
\langle TJJ \rangle = n^{TFF}_\phi \langle TJJ \rangle_\phi + n^{TFF}_\psi \langle TJJ \rangle_\psi.
\end{equation}
(2.15)

As reviewed in section 1.1, a U(1) or simple flavor symmetry \(G_F\) gives rise to the conformal anomalies (1.4) in the presence of suitable background flavor and gravity fields,
\begin{align}
\langle T^\mu_\mu \rangle &\supset -\frac{\tau^F_1}{3} \operatorname{Tr}(D_\mu F^\mu_\nu D^\nu F_{\nu\lambda}) - \frac{\tau^F_2}{4} W_{\mu\nu\rho\lambda} \operatorname{Tr}(F^{\mu\nu} F^{\rho\lambda}) + \frac{\rho^F_1}{3} \operatorname{Tr}(F^{\mu\nu} F^\mu_{\mu\lambda} F^\lambda_{\nu}) + \cdots
\end{align}
(2.16)
The anomaly coefficients \(\tau^F_{1,2}\) and \(\rho^F\) are theory dependent. In the absence of background fields, each conformal anomaly in (2.16) represents a contact term associated with a particular three-point function at separated points. To derive these relations, one can for instance follow [50, 54] and work in position space using the method of differential regularization; alternatively, one can work in momentum space.

It follows that the conformal anomalies \(\tau^F_1\) and \(\tau^F_2\) in (2.16) must be related in a universal, linear way to the three-point function coefficients \(c_{TFF}\) and \(e_{TFF}\) in (2.14), or equivalently to the coefficients \(n^{TFF}_\phi, n^{TFF}_\psi\) in (2.15). Similarly, the conformal anomalies \(\tau^F_1\) and \(\rho^F\) must have a universal, linear relation to the three-point function coefficients \(A_{TFF}\) and \(B_{TFF}\) in (2.8). We can determine these universal linear relations by comparing with various free-field examples that have been worked out in the literature, see for instance [13,
Converting to our conventions, we find that free field theories satisfy
\[ \tau_2^F = \frac{1}{45} (T_\phi - 4 T_\psi), \quad \rho^F = -\frac{1}{30} (T_\phi - 4 T_\psi). \] (2.17)

By comparing this to the free-field formulas (2.10) and (2.14) above, we conclude that
\[ \tau_2^F = \frac{\pi^0}{45} \left( 8 e_{TFF} - \frac{1}{3} c_{TFF} \right), \quad \rho^F = \frac{\pi^0}{15} \left( B_{FFF} - \frac{3}{2} A_{FFF} \right). \] (2.18)

Together with (2.6), this completes the relations between two- and three-point function coefficients of currents and stress tensors, and the conformal anomalies associated with flavor symmetries in (2.16). We summarize these relations here,
\[ \tau_1^F = \frac{4 \pi^6}{5} C_F, \quad \tau_2^F = \frac{\pi^0}{45} \left( 8 e_{TFF} - \frac{1}{3} c_{TFF} \right), \quad \rho^F = \frac{\pi^0}{15} \left( B_{FFF} - \frac{3}{2} A_{FFF} \right). \] (2.19)

3 Current and stress-tensor supercorrelators in six-dimensional SCFTs

In this section we examine the constraints of supersymmetry on two- and three-point functions of flavor currents and stress tensors in six-dimensional SCFTs. We will show that the conformal anomalies of all \( \mathcal{N} = (1, 0) \) SCFTs satisfy the following universal relations,
\[ c_1 = \frac{1}{2} (c_2 + c_3), \quad \tau_2^F = \rho^F = 0. \] (3.1)

Here \( G_F \) can be any U(1) or simple flavor symmetry. We also show that the conformal anomalies associated with the SU(2)_R symmetry can be expressed in terms of the \( c_i \) conformal anomalies as follows,
\[ \tau_1^R = c_3, \quad \tau_2^R = \frac{1}{2} (c_3 - c_1), \quad \rho^R = \frac{3}{2} (c_1 - c_3). \] (3.2)

Finally we briefly discuss conformal collider bounds on these anomaly coefficients.

3.1 Free SCFTs

We begin by considering a theory of \( n_H \) free hypermultiplets and \( n_T \) free tensor multiplets. As we will see below, some relations uncovered in this simple free-field context continue to hold for general \( \mathcal{N} = (1, 0) \) SCFTs. In fact, the input from free field theories will be used in the general proof of these relations below.

Using (2.13) with \( n_{TTT}^\phi = 4 n_H + n_T, n_{TTT}^\psi = n_T + n_H, \) and \( n_{TTT}^B = n_T, \) we find that
\[ c_1 = \frac{n_H + 8 n_T}{9}, \quad c_2 = \frac{n_H + 44 n_T}{45}, \quad c_3 = \frac{n_H + 4 n_T}{5}. \] (3.3)

Note that these formulas are consistent with (3.1), and that a free \( \mathcal{N} = (2, 0) \) tensor multiplet with \( n_H = n_T = 1 \) indeed satisfies \( c_1 = c_2 = c_3 = 1. \)

In supersymmetric theories we distinguish between flavor symmetries, which commute with the supercharges, and R-symmetries, which do not:
• **Flavor Symmetries:** only hypermultiplets can carry flavor charge, with \( T_F^F = 4T_P^P = 4T_H^H \), where \( T_H^H \) is the quadratic index of the hypermultiplet flavor representation. Thus, the free-field expression for the flavor-current two-point function coefficients is

\[
\tau_1^F = 2T_H^H. \tag{3.4}
\]

Note that a single free hypermultiplet has an SU(2) \( F \) flavor symmetry with \( T_F^F = 1 \) and hence \( \tau_1^F = 1 \). This is easy to see by reformulating the theory as a half-hyper in the doublet representation of SU(2) \( F \).

The free-field expression for the \( \langle J^F J^F J^F \rangle \) flavor-current three-point function is obtained from (2.10) by setting \( T_P^F = 4T_H^H \) and \( T_P^P = T_H^H \), so that

\[
A_{FFF} = \frac{3}{2\pi^9}T_H^H, \quad B_{FFF} = \frac{3}{2}A_{FFF} = \frac{9}{4\pi^9}T_H^H. \tag{3.5}
\]

For the \( \langle T J^F J^F \rangle \) three-point function, it follows from (2.14) that

\[
c_{TFJ} = \frac{72}{5\pi^9}T_H^H, \quad e_{TFJ} = \frac{1}{24}c_{TFJ} = \frac{3}{5\pi^9}T_H^H. \tag{3.6}
\]

Substituting into the expressions (2.19) for the flavor conformal anomalies gives

\[
\tau_2^F = \rho^F = 0. \tag{3.7}
\]

• **SU(2)_R Symmetry:** the scalars in each hypermultiplet transform as a complex SU(2) \( R \) doublet, so that \( T_P^R = 2n_H \). By contrast, the fermions in every tensor multiplet transform as half-doublets of SU(2) \( R \), so \( T_P^R = \frac{1}{2}n_T \). It follows that the free-field expression for the SU(2) \( R \) current two-point function coefficient is given by

\[
\tau_1^R = \frac{1}{5}(n_H + 4n_T) = c_3. \tag{3.8}
\]

The free-field expressions for the \( \langle J^R J^R J^R \rangle \) and \( \langle T J^R J^R \rangle \) three-point function coefficients take the following form,

\[
\mathcal{A}_{RRR} = \frac{3}{4\pi^9}n_H, \quad \mathcal{B}_{RRR} = \frac{1}{8\pi^9}(n_H + 8n_T),
\]

\[
c_{TRR} = \frac{6}{5\pi^9}(n_H + 5n_T), \quad e_{TRR} = \frac{3}{10\pi^9}n_H. \tag{3.9}
\]

Substituting into (2.19) and comparing with (3.3), we find that

\[
\tau_2^R = \frac{2}{45}(n_H - n_T) = \frac{1}{2}(c_3 - c_1), \quad \rho^R = \frac{1}{15}(n_T - n_H) = \frac{1}{4}(c_1 - c_3). \tag{3.10}
\]

### 3.2 Supercorrelators for conserved supermultiplets: overview

We will apply the superspace formalism of [57] to the two- and three-point functions of operators in conserved flavor-current and stress-tensor supermultiplets. Analogous considerations for four-dimensional SCFTs can be found in [58–60]. Here we will give a brief survey of the results that will follow from this analysis (see section 3.3 below for details):
\begin{itemize}
  \item The two-point functions of all operators in the stress-tensor supermultiplet, including \( T_{\mu\nu} \) itself and the SU(2)\(_R\) current \( J^R_\mu \), are determined by the two-point functions of its bottom component (i.e. the superconformal primary); all of them can be expressed in terms of the conformal anomaly \( c_3 \). Likewise, the two-point functions of all operators in a flavor-current supermultiplet are determined by the two-point functions of its bottom component; all of them can be expressed in terms of the conformal anomaly \( \tau_1^F \). The two-point function of the flavor-current supermultiplet with the stress-tensor supermultiplet vanishes. The fact that two-point functions of supermultiplets are determined by those of their bottom components reflects the absence of nilpotent invariants for two-point functions. Such invariants first appear at the level of three-point functions [57–60].
  
  \item All non-zero three-point functions of operators in the supermultiplet of a flavor-current \( J^a_\mu \) are entirely determined by the Lie algebra structure constants \( f^{abc} \) and the two-point function coefficient \( \tau_1^F \). This differs from the non-supersymmetric case, where \( B_{FFF}/A_{FFF} \), or equivalently the conformal anomaly \( \rho^F \) in (1.4), are independent quantities that appear in three-point functions. Superconformal symmetry thus fixes these quantities, and to determine their values it suffices to compare to the free-field formulas (3.5) and (3.7). This implies that any \( \mathcal{N} = (1,0) \) SCFT in six dimensions satisfies
  \begin{equation}
  \left| \frac{B_{FFF}}{A_{FFF}} \right|_{\text{SCFT}} = \frac{3}{2}, \quad \left| \rho^F \right|_{\text{SCFT}} = 0. \tag{3.11}
  \end{equation}
  
  \item All three-point functions involving one stress-tensor supermultiplet operator and two flavor-current supermultiplet operators, such as \( \langle T J^F J^F_i \rangle \) itself, are completely determined by \( \tau_1^F \). This implies that the ratio \( c_{TFF}/c_{TFF} \), and thus the conformal anomaly coefficient \( \tau_2^F \), are determined by supersymmetry. Again, their values can then be computed from the free-field case, so that all six-dimensional \( \mathcal{N} = (1,0) \) SCFTs satisfy
  \begin{equation}
  \left| \frac{c_{TFF}}{c_{TFF}} \right|_{\text{SCFT}} = \frac{1}{24} \quad \text{hence} \quad \tau_2^F \bigg|_{\text{SCFT}} = 0. \tag{3.12}
  \end{equation}
  
  \item All non-zero three-point functions of operators in the stress-tensor supermultiplet are completely determined by two coefficients, one of which is related to the two-point function coefficient \( c_3 \) by a Ward identity. In particular, this proves that the three conformal anomalies \( c_1, c_2, c_3 \) necessarily satisfy a linear relation in any six-dimensional SCFT, as originally conjectured in [9]. As before, the coefficients in this linear relation are fixed by the free-field formulas (3.3),
  \begin{equation}
  c_2 = \frac{1}{2} (c_1 + c_3). \tag{3.13}
  \end{equation}
  
  Since the SU(2)\(_R\) current \( J^R \) also resides in the stress-tensor supermultiplet, it follows that its three-point functions are also linear combinations of \( c_1 \) and \( c_3 \); the coefficients are determined by the free-field formulas (3.9) and (3.10). It follows that all \( \mathcal{N} = \)}
(1, 0) SCFTs satisfy
\[ \pi^9 A_{RRR} = \frac{3}{4} (10c_3 - 9c_1), \quad \pi^9 B_{RRR} = \frac{9}{8} c_1, \quad \tau_2^R = \frac{1}{2} (c_3 - c_1). \quad (3.14) \]
This is compatible with the Ward identity relating the SU(2)_R current three- and two-point functions: \( \pi^9 (\frac{1}{6} A_{RRR} + B_{RRR}) = C_R = 5c_3 / 4\pi^6 \), which fits (2.6) with \( \tau_1^R = c_3 \).

Likewise, the coefficients \( e_{TRR} \) and \( c_{TRR} \) that determine the three-point functions of one stress tensor and two SU(2)_R currents are universal linear combinations of \( c_1 \) and \( c_3 \) that can be fixed by free-field reasoning (see again (3.9) and (3.10)),
\[ \pi^9 c_{TRR} = \frac{27}{10} c_1 + \frac{9}{2} c_3, \quad \pi^9 e_{TRR} = 3c_3 - \frac{27}{10} c_1, \quad \rho^R = \frac{1}{4} (c_1 - c_3). \quad (3.15) \]

The main goal of the superspace analysis below is to cut down the number of independent structures in the two- and three-point functions of flavor-current and stress-tensor supermultiplets by imposing the constraints of superconformal symmetry. Once the number of these structures is sufficiently small, their coefficients can be determined by free-field reasoning.

The constraints of conformal symmetry on two- and three-point functions are standard: two-point functions are always determined by one overall coefficient. By contrast, three-point functions are described by finitely many tensor structures, whose exact number can depend on the Lorentz representations of the operators participating in the three-point functions. Both of these results follow from the fact that the bosonic conformal generators can be used to bring the spacetime coordinates of the operators appearing in these correlators to standard form (see for instance [61] and references therein for a recent discussion).

In superspace, the \( Q \) and \( S \) supercharges can be used to set the Grassmann coordinates of two operators to prescribed values. Thus all two-point functions of operators residing in a supermultiplet can be expressed in terms of the two-point function of its bottom component. However, at the level of three-point functions, superconformal symmetry alone does not simplify the dependence of the supercorrelator on the third Grassmann coordinate.

The upshot is that superspace three-point functions generally depend on a non-trivial Grassman variable \( \Theta \) that can be constructed from the superspace coordinates of the three supermultiplets inside the correlator. The coefficient functions that appear in a \( \Theta \)-expansion of such a supercorrelator represent the three-point functions of the individual component operators. In the absence of additional constraints, these functions are all independent, and hence the three-point functions of \( Q \)-descendant operators inside a superconformal multiplet are not in general determined by the three-point function of the superconformal primary.

Additional constraints do arise if some of the supermultiplets in the correlator are short. The shortening condition implies that all correlators involving null states of the multiplet must vanish. In some cases, such constraints are sufficient to determine the three-point functions of all \( Q \)-descendants in terms of the three-point function of the superconformal primaries (see e.g. [60, 62, 63] for a related discussion in four dimensions).
As we will discuss below, the superspace three-point function $\langle \mathcal{T}(z_1)\mathcal{T}(z_2)\mathcal{T}(z_3) \rangle$ of the stress-tensor multiplet can be expressed in terms of a homogeneous function $H^{TTTT}(X, \Theta)$ (here the bosonic variable $X$ is the superpartner of $\Theta$), which is completely determined up to three independent coefficients $C_{1,2,3}^{TTT}$. We then impose the shortening condition on $\mathcal{T}$, which amounts to setting a level-three null state and its descendants to zero. As we will see, this imposes one linear relation on the coefficients $C_{1,2,3}^{TTT}$, so that the $\langle \mathcal{T}(z_1)\mathcal{T}(z_2)\mathcal{T}(z_3) \rangle$ supermultiplet three-point function is in fact completely determined by two independent constants. Once this has been established, free-field reasoning is sufficient to deduce all facts about the stress-tensor supermultiplet three-point function that were summarized above.

When analyzing the three-point supercorrelator $\langle \mathcal{J}^{(1ij)}(z_1)\mathcal{J}^{(12j)}(z_2)\mathcal{J}^{(13j)}(z_3) \rangle$ of three flavor current multiplets, as well as supercorrelator $\langle \mathcal{J}^{(1ij)}(z_1)\mathcal{J}^{(12j)}(z_2)\mathcal{T}(z_3) \rangle$ of two flavor-current multiplets and one stress-tensor multiplet, we must impose the shortening condition satisfied by $\mathcal{J}^{(ij)}$ in addition to that of $\mathcal{T}$. This completely determines both correlators up to one overall coefficient, which in turn is related to the flavor-flavor two-point function coefficient $\tau_1^F$ by a Ward identity.

### 3.3 Supercorrelators for conserved supermultiplets: details

$\mathcal{N} = (1,0)$ superspace in $d = 6$ involves spacetime positions $x^\mu \in [0, 1, 0]_1^{(0)}$, which we will often write as antisymmetric bispinors $x^{[\alpha \beta]} \sim \varepsilon^{\alpha \beta \gamma \delta} x_{[\gamma \delta]}$ (see below), and symplectic-Majorana Grassmann coordinates $\theta^x_i \in [0, 0, 1]_{-1/2}^{(1)}$, where $\alpha = 1, \ldots, 4$ is a chiral spinor index and $i = 1, 2$ an SU(2)$_R$ doublet index. The latter can be raised and lowered using $\varepsilon^{ij}, \varepsilon_{ij}$. The supercharges and supercovariant derivatives act via the following differential operators,

$$Q^i_\alpha = \frac{\partial}{\partial \theta^x_i} + i\theta^{\dot{\beta}} \partial_{\beta \alpha}, \quad D^i_\alpha = \frac{\partial}{\partial \theta^{\dot{x}}_i} - i\theta^{\dot{\beta}} \partial_{\dot{\beta} \alpha},$$

which satisfy $\{Q^i_\alpha, Q^j_\beta\} = 2i\varepsilon^{ij} \partial_{\alpha \beta}$, $\{D^i_\alpha, D^j_\beta\} = -2i\varepsilon^{ij} \partial_{\alpha \beta}$, and $\{D^i_\alpha, Q^j_\beta\} = 0$.

In the notation of [28, 29], the stress-tensor of $\mathcal{N} = (1,0)$ SCFTs resides in a $B_3[0,0,0]_4^{(0)}$ superconformal multiplet with $40_B + 40_F$ bosonic and fermionic component operators,

$$\mathcal{T} \in [0,0,0]_4^{(0)}, \quad \psi^i_{T,\alpha} \in [1,0,0]_{4,5}^{(1)}, \quad J^R_{(ij)} \in [0,1,0]_{5}^{(2)}, \quad C_{T,(\alpha \beta)} \in [2,0,0]_5^{(0)}, \quad S^i_{\mu \alpha} \in [1,1,0]_{5,5}^{(1)}, \quad T_{\mu \nu} \in [0,2,0]_6^{(0)}.$$  

(3.17)

The null states of the multiplet, which must be set to zero, first occur at level three,

$$\varepsilon^{\alpha \beta \gamma \delta} Q^i_\alpha Q^j_\beta Q^k_\gamma \mathcal{T} = (\mathcal{V}^i)^{(ijk)} \in [0,0,0]_{5,5}^{(3)} \quad \rightarrow \quad 0.$$  

(3.18)

This enforces the conservation equations $\partial^\mu J^R_{(ij)} = \partial^\mu S^i_{\mu \alpha} = \partial^\mu T_{\mu \nu} = 0$ and ensures that $S^i_{\mu \alpha}$ and $T_{\mu \nu}$ are suitably traceless. In superspace, the shortening condition (3.18),
and the resulting field content (3.17), can be expressed as follows,
\[ \varepsilon^{\alpha\beta\gamma} D_\alpha^i D^j D_k \mathcal{T} = 0, \quad \mathcal{T}(x, \theta) = \mathcal{T}(x) + \psi^{ij}_{\mathcal{T},\alpha}(x) \theta^\alpha_i + J^{R(ij)}_{[\alpha\beta]}(x)(\theta \theta^{[\alpha\beta]}_{ij}) + \cdots. \quad (3.19) \]

A conserved \( \mathcal{N} = (1,0) \) flavor current resides in a \( D_1[0,0,0]_4 \) multiplet \([28,29]\), which contains \( 8_B + 8_F \) operators,
\[ \mathcal{J}^{a(ij)} \in [0,0,0]_4^{(2)}, \quad J^a_\alpha \in [1,0,0]_4^{(1)}, \quad J^a_\mu \in [0,1,0]_5^{(0)}. \quad (3.20) \]

Here \( a \) is an adjoint flavor index. The conservation law for the flavor current \( J^a_\mu \sim J^{[a\beta]}_{[\alpha\beta]} \) is encoded by the level-one null state \([1,0,0]_4^{(3)} \to 0 \) and its descendants. In superspace,
\[ \mathcal{D}_\alpha^i \mathcal{J}^{a(ij)}(x, \theta) = 0, \quad \mathcal{J}^{a(ij)}(x, \theta) = \mathcal{J}^{a(ij)}(x) + J^{a(i)}_\alpha(x) \theta^{\alpha_j} + \theta^{\alpha_j} \theta^{\beta_i} J^a_{[\alpha\beta]}(x) + \cdots. \quad (3.21) \]

Two-point functions can be written in terms of coordinates that are invariant under superspace translations \([57]\),
\[ \chi^{a_1}_{a_2} \equiv x^{a_1} - x^{a_2} + 2i \theta^a_1 \theta^a_1, \quad \theta_1^{a_1,1} \equiv \theta_1^{a_1} - \theta_2^{a_1}. \quad (3.22) \]
where
\[ x^{a_1} \equiv x^{a_1} + i \theta^a_1 \theta^a_1 = -x^{a_1}. \quad (3.23) \]

If the bottom component of the supermultiplet transforms in a non-trivial SU(2) \( R \)-representation, the \( R \)-symmetry indices of the supercorrelation function are accounted for by the quantities \([57]\) (see also \([60,64]\) for a similar analysis in the context of \( d = 4, \mathcal{N} = 2 \) SCFTs)
\[ u_i^j(z_{12}) = \delta_i^j - 4i \theta_{12} \chi_{12} \theta_{12}^i (\det \chi_{12})^{-1/2}. \quad (3.24) \]

The superspace two-point function of the stress-tensor supermultiplet \( \mathcal{T}(z) \) is completely determined up to an overall coefficient \( c_T \sim C_T \), giving the superspace generalization of (2.1),
\[ \langle \mathcal{T}(z_1) \mathcal{T}(z_2) \rangle = \frac{c_T}{(\det \chi_{12})^{2}}. \quad (3.25) \]
The two-point functions of all operators in the \( \mathcal{T} \)-multiplet follow upon expanding in \( \theta_1, \theta_2 \). In particular, the \( J^{R(ij)}_{a} \) and \( T_{\mu
u} \) two-point functions are obtained from (3.25) by extracting the \( \theta_1^i \theta_2^j \) and the \( \theta_1^i \theta_2^j \) terms, respectively. Comparing with the general expressions (2.1) for current and stress-tensor two-point functions, it follows that \( c_T \sim T^R \sim c_3 \). The proportionality constants can be fixed by comparing to a free \( \mathcal{N} = (1,0) \) hyper- or tensor multiplet. For a free tensor multiplet, the bottom component is \( \mathcal{T} \sim \varphi^2 \), where \( \varphi \) is the free scalar in the tensor multiplet; for the free hypermultiplet, the bottom component is \( \mathcal{T} \sim h_{v'i} h^{v'i} \), where \( i = 1,2 \) is an SU(2) \( R \) doublet index, \( v' \) is an SU(2) \( F \) flavor doublet index, and the hypermultiplet scalars \( h_{v'i} \) obey a reality condition \( (h_{v'i})^* \sim h^{v'i} \).\[8\]

Similarly, the two-point functions of flavor-current supermultiplets \( \mathcal{J}^{a(ij)} \) are completely determined up to an overall coefficient \( c_J \),
\[ \langle \mathcal{J}^{a_{(i_1,j_1)}}_{(i_2,j_2)}(z_{12}) \rangle = c_J \delta^{ab} \frac{u_{i_1}^{i_2}(z_{12})u_{j_1}^{j_2}(z_{12}) + u_{i_1}^{i_2}(z_{12})u_{j_1}^{j_2}(z_{12})}{(\det \chi_{12})^{2}}. \quad (3.26) \]

\[8\]See \([66]\) for a related recent discussion in the context of \( d = 4, \mathcal{N} = 2 \) theories.
The factors of $u_i^j(z_{12})$ (defined in (3.24)) account for the SU(2)$_R$ representation of $J^{a(ij)}$. The actual flavor-current two-point function arises from the $\theta_1^a\theta_2^b$ component of (3.26). Finally, the two-point function of a flavor-current and a stress-tensor multiplet must vanish,

$$\langle T(z_1)J^{a(ij)}(z_2) \rangle = 0.$$  \hspace{1cm} (3.27)

For the bottom components, this follows from SU(2)$_R$ symmetry, while superconformal symmetry ensures that the same is true for all other operators in these multiplets.

We now turn to the three-point functions involving the $T$ and $J^{a(ij)}$ multiplets. As in [50, 57], they can be expressed in terms of a superspace variable $Z \equiv (X^\mu,\Theta^{a(i)}) \in \mathbb{R}^{6|8}$ that is formed from the three superspace coordinates $z_{1,2,3}$ as follows,

$$X_{[\alpha\beta]} = \left(\chi^{-1}_{13}\chi_{12}\chi_{32}^{-1}\right)_{[\alpha\beta]} , \quad \Theta^i_\alpha = i \left(\chi^{-1}_{13}\theta_1^i - \chi^{-1}_{23}\theta_2^i\right)_\alpha .$$  \hspace{1cm} (3.28)

The matrix $\chi_{12}^{\alpha\beta}$ was defined in (3.22) (the extension to other pairs of points is obvious), while $(\chi^{-1}_{12})_{\alpha\beta}$ is its inverse matrix. Note that $X_{[\alpha\beta]} \in [0,1,0]^{(0)}_1$ and $\Theta^i_\alpha \in [1,0,0]^{(1)}_{1/2}$ have different scaling dimensions than the superspace coordinates $x^\mu \in [0,1,0]^{(0)}_1$ and $\theta^{a(i)} \in [0,0,1]^{(1)}_{1/2}$ discussed above (3.16); moreover $\Theta^i_\alpha$ and $\theta^{a(i)}$ are spinors of opposite chirality.

The three-point supercorrelator of any Lorentz- and SU(2)$_R$ singlet operators takes the form

$$\langle O_1(z_1)O_2(z_2)O_3(z_2) \rangle \equiv H(Z_3) \left(\frac{\det(\chi_{13})}{\det(\chi_{23})}\right)^{\Delta / 2} H(X,\Theta) .$$  \hspace{1cm} (3.29)

where $H(\lambda X,\lambda^{1/2}\Theta) = \lambda^{\Delta_1 - \Delta_1 - \Delta_2} H(X,\Theta)$. The function $H$ can always be written as follows,

$$H(X,\Theta) = \frac{1}{(X^2)^{\frac{1}{2}(\Delta_1+\Delta_2-\Delta_3)}} \left( C^{O_1O_2O_3}_1 + C^{O_1O_2O_3}_2 \frac{(X\Theta^2)^2}{X^4} + C^{O_1O_3O_3}_3 \frac{\Theta^8}{X^4} \right).$$  \hspace{1cm} (3.30)

Here $(\Theta^2)^{[\alpha\beta]} \equiv \Theta^\alpha\Theta^\beta\epsilon^{\epsilon\epsilon\epsilon} \in [2,0,0]^{(0)}_0$ is the only SU(2)$_R$ invariant that can be formed from the $\Theta^i_\alpha$. It transforms in the same Lorentz representation as a self-dual three-form $H^{IJK}$, with $I, J, K = 1, \ldots, 6$ and $*H = H$. The only independent Lorentz scalar that can be constructed purely from $(\Theta^2)^{[\alpha\beta]}$ is $\epsilon^{\alpha\beta\gamma\delta} \epsilon^{\alpha'\beta'\gamma'\delta'} (\Theta^2)^{\alpha\alpha'} (\Theta^2)^{\beta\beta'} (\Theta^2)^{\gamma\gamma'} (\Theta^2)^{\delta\delta'}$. (In terms of $H^{IJK}$, viewed as a trivalent vertex, this index contraction is a tetrahedron.) All remaining Lorentz and SU(2)$_R$ invariants are built using the combination $(X\Theta^2)^{\alpha\beta} = X^{[\alpha\gamma]}(\Theta^2)^{\gamma\beta}$, which is in the adjoint representation $[1,0,1]$ of the Lorentz group; it can also be written as $(X\Theta^2)^{IJK} = H^{IJK} X_K$. The quadratic Casimir invariant of this Lorentz adjoint, $\text{Tr}(X\Theta^2)^2 \equiv (X\Theta^2)^2$ appears as the middle term in (3.30). Note that the Lorentz adjoint $(X\Theta^2)$ does not have a cubic Casimir invariant, since $\text{Tr}(X\Theta^2)^3 = 0$. Finally, the quartic Casimir $\text{Tr}(X\Theta^2)^4$ is not independent of the invariants that were already introduced above.

If we expand the three-point function (3.30) in components, the coefficient $C^{O_1O_2O_3}_{2,3}$ determines the three-point function of the superconformal primaries. The coefficients $C^{O_1O_2O_3}_{1,2,3}$ are associated with three-point functions of descendant operators. For long multiplets, the coefficients $C^{O_1O_2O_3}_{1,2,3}$ are independent, but for short multiplets they satisfy additional constraints that follow from the requirement that the null-state multiplet vanish in superspace.
Let us apply the general reasoning above to the three-point function of stress-tensor multiplets. Setting $O_i (z_i) = T (z_i)$ and $\Delta_i = 4$ in (3.30), we obtain
\[
(\mathcal{T}_1 (z_1) \mathcal{T}_2 (z_2) \mathcal{T}_3 (z_3)) = \frac{H_{TTTT} (X, \Theta)}{(\det \chi_{13})^2 (\det \chi_{23})^2},
\]
(3.31)
\[H_{TTTT} (X, \Theta) = C^T_{TTTT} \frac{1}{X^1} + C^T_{TTTT} \frac{(X \Theta^2)^2}{X^8} + C^T_{TTTT} \Theta^8 \frac{1}{X^8}.
\]
We must now impose the shortening condition (3.18), as well as exchange symmetry under $z_1 \leftrightarrow z_2 \leftrightarrow z_3$, since the three supermultiplets are identical. In the present context, exchanging $z_1 \leftrightarrow z_2$ takes $Z \rightarrow -Z$ and does not constrain the coefficients in (3.31). However, the shortening condition (3.18) can be shown to lead to the following constraint on the function $H_{TTTT}$ that appears in (3.31),
\[
\varepsilon_{\alpha \beta \gamma \delta} \hat{D}_i^\alpha \hat{D}_j^\beta \hat{D}_k^\gamma H_{TTTT} = 0, \quad \hat{D}_i^\alpha = \frac{\partial}{\partial \Theta_{i}} + i \Theta_{i}^j \frac{\partial}{\partial X_{j \alpha}}.
\]
(3.32)
To analyze this constraint, we count monomials in $X^{[\alpha \beta]}$ and $\Theta^i_\alpha$ that share its $[1, 0, 0]^{(3)}$ Lorentz and $R$-symmetry quantum numbers and could therefore appear as terms in (3.32). Naively, there are two such monomials: $[(X \Theta^3)^{[i (jk)}] = \varepsilon_{\alpha \alpha_1 \alpha_2 \alpha_3} X^{\alpha_1 \beta_1} X^{\alpha_2 \beta_2} X^{\alpha_3 \beta_3} \Theta^i_{\beta_1} \Theta^j_{\beta_2} \Theta^k_{\beta_3}$; and $[\Theta^5_{[i (jk)}$, the unique contraction of five $\Theta$’s with $[1, 0, 0]$ Lorentz quantum numbers and $R = 3$. However, $[(X \Theta^3)^{[i (jk)} = 0$ vanishes identically. This can be seen by noting that the $\Theta^3$ part has to be in the $[0, 0, 1]^{(3)}$, which can give a $[1, 0, 0]$ Lorentz representation by tensoring with a $[2, 0, 0]$. However, the latter is a three-form (i.e. it is a completely antisymmetric tensor product of three $[0, 1, 0]$ vectors), while $X^3$ is a completely symmetric product of three vectors. Therefore their contraction $(X \Theta)^3 \sim X^3 \Theta^3$ vanishes identically.

It follows that evaluating the differential operator on the left-hand side of (3.32) on the function $H_{TTTT}$ in (3.31) can (schematically) only give terms of the form
\[
\varepsilon_{\alpha \beta \gamma \delta} \hat{D}_i^\alpha \hat{D}_j^\beta \hat{D}_k^\gamma H_{TTTT} (X, \Theta) \sim [\Theta^5_{[i (jk)}.
\]
(3.33)
Since the operator $\hat{D}_i^\alpha$ changes the number of $\Theta$’s by $\pm 1$, the $\hat{D}_3^\alpha$ operator on the left-hand side can only produce the number of $\Theta$’s on the right-hand side by acting on the terms proportional to $C^T_{TTTT}$ and $C^T_{TTTT}$ in (3.31). It follows that $C^T_{TTTT}$ is unconstrained, and that there is one linear constraint on $C^T_{TTTT}$ and $C^T_{TTTT}$. This shows that all three-point correlators of operators in the stress-tensor supermultiplet can be expressed in terms of at most two linearly independent coefficients. Moreover, there is a Ward identity that relates one linear combination of these two coefficients to the two-point function coefficient $c_T \sim c_3$.

As outlined in section 3.2, it follows that the $c_1$ conformal anomalies necessarily satisfy a linear relation in all $\mathcal{N} = (1, 0)$ SCFTs. The precise form of this relation can be determined by examining free hyper- and tensor multiplets, as discussed around (3.13).

We can also use superspace to analyze three-point correlators that involve a flavor-current multiplet (3.21). This requires writing down general combinations of $u$’s, $\chi$’s, $\psi$’s, $\xi$’s, $\phi$’s and $\Psi$’s.
X, and Θ with the correct symmetries and quantum numbers, and then imposing the shortening conditions \((D^3)^{(ijk)\alpha}\mathcal{T} = 0\) and \(D_i^T J^{jk} = 0\). The condition on the flavor current is particularly constraining, because the analogue of (3.33) now involves multiple independent structures on the right-hand side. The condition that all of these vanish separately determines the relative coefficients of all terms in the Θ-expansion.

The upshot is that all three-point functions involving a \(n\)-avor-current multiplet are fully determined up to an overall coefficient. Moreover, Ward identities relate this overall coefficient to a two-point function coefficient \(c_F\). The results are

\[
\langle J^{a(i_1j_1)}(z_1)T(z_2)T(z_3) \rangle = 0, \tag{3.34}
\]

and

\[
\langle J^{a(i_1j_1)}(z_1)J^{b(i_2j_2)}(z_2)J^{c(i_3j_3)}(z_3) \rangle = c_F f^{abc} \langle J^{(i_1j_1)}(z_1)J^{(i_2j_2)}(z_2)J^{(i_3j_3)}(z_3) \rangle \text{canonical}, \tag{3.35}
\]

and

\[
\langle J^{a(i_1j_1)}(z_1)J^{b(i_2j_2)}(z_2)T(z_3) \rangle = c_F \delta^{ab} \langle J^{(i_1j_1)}(z_1)J^{(i_2j_2)}(z_2)T(z_3) \rangle \text{canonical}. \tag{3.36}
\]

Here the canonical correlators on the right-hand side are specific, completely determined functions on superspace, which are fixed by exchange symmetries and null-state conditions. This six-dimensional analysis is closely analogous to the four-dimensional analysis in [60]. For this reason, we do not spell out all the details here. Once it has been established that the correlators in (3.35) and (3.36) only depend on the theory under consideration via the two-point function coefficient \(c_F\) and the flavor Lie algebra structure constants \(f^{abc}\), we can use free-field reasoning as in sections 3.1 and 3.2 to derive all other results quoted there.

### 3.4 Conformal collider inequalities

The average null energy condition [67, 68] places unitarity bounds on the three-point function coefficients discussed above. These bounds are conveniently derived using the conformal collider setup of [9, 10, 69]. (See [70–73] for some related recent work.) As described in [9, 55], the six-dimensional version of the collider bounds of [10] can be written as

\[
1 - \frac{1}{5} t_2 - \frac{2}{35} t_4 \geq 0, \quad 1 - \frac{1}{5} t_2 - \frac{2}{35} t_4 + \frac{1}{2} t_2 \geq 0, \quad 1 - \frac{1}{5} t_2 - \frac{2}{35} t_4 + \frac{4}{5} (t_2 + t_4) \geq 0, \tag{3.37}
\]

where \(t_{2,4}\) are linear combinations of the \(c_i\) conformal anomalies given in [9]. In terms of the parameterization in (2.12), these inequalities take the simple form

\[
n^T_{TTT} \geq 0, \quad n^T_{TTT} \geq 0, \quad n^T_{TTT} \geq 0. \tag{3.38}
\]

It was pointed out in [10] that \(t_4 = 0\) for \(d = 4\) SCFTs. By analogy, it was conjectured in [9] that supersymmetry should impose the linear relation \(t_4 = 0\) on the \(c_i\) conformal
anomalies of \( d = 6 \) SCFTs, and it was verified that this is indeed the case in free-field examples. In our conventions, the condition \( t_4 = 0 \) precisely coincides with the relation (3.13) derived above. The remaining inequalities in (3.37) then reduce to [9],

\[-\frac{5}{3} \leq t_2 \leq 5 \quad \iff \quad \frac{5}{9} \leq \frac{c_1}{c_3} \leq \frac{31}{27}. \quad (3.39)\]

The lower bound is saturated by a free hypermultiplet. In fact, the upper bound in (3.39) can be strengthened to \( \frac{10}{9} < \frac{34}{27} \) in SCFTs, and this stronger upper bound is saturated by a free tensor multiplet. Note that unitarity of the two-point function implies \( c_3 > 0 \), so that (3.39) gives \( c_1 > 0 \). Similarly, using (3.13) gives \( (c_2/c_3) = 2(c_1/c_3) - 1 \) so that (3.39) implies

\[ \frac{1}{9} < \frac{c_2}{c_3} < \frac{35}{27}, \quad (3.40)\]

and hence \( c_2 > 0 \).

To derive stronger constraints on the \( c_i \) in the case of SCFTs we follow [10] and apply the conformal collider constraints to states created by the \( R \)-current. Let us first review the non-supersymmetric conformal collider bounds on states created by a conserved flavor current \( J^F_\mu \) in \( d \) dimensions. As reviewed below (2.13), the \( \langle T^F J^F \rangle \) correlator is parametrized by two coefficients, \( c_{TFF} \) and \( e_{TFF} \), one linear combination of which is fixed by the flavor-current two-point function coefficient \( C_F \) via \( 2S_d (c_{TFF} + e_{TFF}) = dC_F \) (see [50, 51] for details). As shown in [70, 74], the ratio \( c_{TJJ} / C_F \) satisfies the following \( d \)-dimensional collider bounds,

\[ \frac{(d - 2)\Gamma\left(\frac{1}{2}d + 1\right)}{2(d - 1)\pi^{\frac{d}{2}}} \leq \frac{c_{TFF}}{C_F} \leq \frac{\Gamma\left(\frac{1}{2}d + 1\right)}{2\pi^{\frac{d}{2}}}, \quad (3.41)\]

where the first inequality is saturated for free scalars and the second one for free fermions. In \( d = 6 \) we can rewrite these inequalities as

\[ 0 \leq \frac{c_{TFF}}{c_{TJJ}} \leq \frac{1}{4}, \quad (3.42)\]

where the order of the inequalities has been reversed, i.e. the first one is saturated for free fermions and the second one for free scalars.

We can now apply (3.42) to the \( \langle T^R J^R \rangle \) correlator in SCFTs. Substituting the free-field formulas for \( c_{TRR}, e_{TRR} \) in terms of \( c_1, c_3 \) in (3.15) into these inequalities, we find that

\[ \frac{5}{9} \leq \frac{c_1}{c_3} \leq \frac{10}{9} \quad \iff \quad \frac{1}{9} \leq \frac{c_2}{c_3} \leq \frac{11}{9}. \quad (3.43)\]

The lower bound coincides with that in (3.39), but the upper bound is stronger; it is saturated by a free \( \mathcal{N} = (1, 0) \) tensor multiplet. In terms of the free-field parameterization of the \( c_i \) conformal anomalies in (3.3), the inequalities (3.42) reduce to the intuitive requirement that

\[ n_H \geq 0, \quad n_T \geq 0. \quad (3.44)\]
4 Anomaly multiplet relations on the tensor branch

In this section we explore how the anomaly multiplet relations derived above are reflected on the tensor branch of $\mathcal{N} = (1,0)$ SCFTs in six dimensions. This leads to a simple, intuitive argument for some of these relations.

4.1 Dilaton effective action on the tensor branch

Here we closely follow the discussion in [24], but also make some new observations. On the tensor branch, the SU(2)$_R$ symmetry is unbroken and the massless dilaton field $\varphi$ (i.e. the Nambu-Goldstone boson associated with spontaneous conformal symmetry breaking) resides in a tensor multiplet. The constraints of conformal symmetry on the effective action of $\varphi$ with and without background gravity fields were analyzed in [75]. The additional terms that arise in the presence of background flavor gauge fields were described in [55]. When all background gauge fields are set to zero and the background metric is taken to be the flat Minkowski metric, the minimal low-energy effective action for $\varphi$ schematically takes the form

$$L_{\text{dilaton}} = \frac{1}{2} (\partial \varphi)^2 - b (\partial \varphi)^4 \varphi^3 + \Delta a (\partial \varphi)^6 \varphi^6 + \mathcal{O}(\partial^8).$$

Here, $\Delta a = a_{\text{UV}} - a_{\text{IR}}$ is the change in the conformal $a$-anomaly along the RG flow from the SCFT at the origin to the low-energy effective theory on the tensor branch. A basic fact that will play an important role below is that the coefficient $b$ in (4.1) is subject to a dispersion relation that implies its positivity [76],

$$b \geq 0.$$  \hspace{1cm} (4.2)

This inequality is saturated if and only if $\varphi$ is a free field with trivial scattering S-matrix.

The constraints of $\mathcal{N} = (1,0)$ supersymmetry on the dilaton effective action were analyzed in [24]. In the absence of non-trivial background fields, the $\mathcal{N} = (1,0)$ dilaton effective action on the tensor branch is given by the supersymmetrization of (4.1), with $\varphi$ residing in a tensor multiplet together with its superpartners $\psi^i_\alpha$ and $B$. Here $\psi^i_\alpha$ is a Majorana-Weyl fermion, and $B$ is a two-form gauge field, whose field strength $H = dB$ is self dual (i.e. $H = *H$). The upshot of this analysis is two-fold [24]: the first conclusion is that the supersymmetric completion of the leading 4-derivative term in (4.1) is of the form

$$- b (\partial \varphi)^4 \varphi^3 \quad \longrightarrow \quad - \frac{b}{\langle \varphi \rangle^3} Q^8 (\delta \varphi)^4 + \cdots ,$$

where the ellipsis denotes higher-order terms in the expansion of $\varphi = \langle \varphi \rangle + \delta \varphi$ in fluctuations around its vev. The second conclusion is that the 6-derivative term proportional to $\Delta a$ is in fact related to the term in (4.3) by supersymmetry, which implies the following universal quadratic relation,

$$\Delta a = \frac{98304\pi^3}{7} b^2.$$  \hspace{1cm} (4.4)

This immediately implies positivity of $\Delta a$, and hence the $a$-theorem, for this class of flows [24].
In the presence of background fields, the dilaton effective action (4.1) gets extended in various ways. Among these extensions there are certain additional terms that are needed to compensate any apparent mismatch between the 't Hooft anomalies of the SCFT at the origin and the low-energy theory on the tensor branch. These terms are Green-Schwarz (GS) like couplings that involve the dynamical two-form gauge field $B$ residing in the tensor multiplet and various background field strengths or background curvatures [17, 18], and their supersymmetric completions. Given, for instance, a background flavor field strength $F_{\mu\nu}$, the corresponding GS term takes the form

$$L_{\text{GS}} \supset n_F B \wedge c_2(F).$$

(4.5)

It follows that $c_2(F)$ (the background flavor instanton density) acts as a source for the dynamical $B$-field, whose field-strength is $H$,

$$dH \supset n_F c_2(F).$$

(4.6)

This in turn implies that $n_F$ is an integer. The supersymmetric completion of (4.5) contains a dilaton coupling $\sim n_F \phi \text{tr}(F_{\mu\nu}F^{\mu\nu})$. Together with (4.5), this Lagrangian is similar to the interacting gauge-tensor Lagrangians used to described $\mathcal{N} = (1, 0)$ SCFTs in [36], except that here the gauge fields are fixed backgrounds associated with global flavor symmetries while only the tensor multiplet is dynamics.

In addition to the flavor background fields discussed above, the tensor multiplet containing $B$ and $\varphi$ also couples to supergravity background fields — in particular a background metric and background gauge fields for the $\text{SU}(2)_R$ symmetry. Here we will briefly review these terms, following [24]. The GS terms involving the dynamical $B$-field and supergravity background fields are

$$L_{\text{GS}} \supset B \wedge (xc_2(R) + y\eta_1(T)), $$

(4.7)

where $x, y$ are real coefficients. These terms account for the following mismatches $\Delta\alpha = \alpha_{\text{UV}} - \alpha_{\text{IR}}$ etc. in the $\text{SU}(2)_R$ and diffeomorphism 't Hooft anomaly coefficients (1.10),

$$\Delta\alpha \sim x^2, \quad \Delta\beta \sim 2xy, \quad \Delta\gamma \sim y^2, \quad \Delta\delta = 0.$$ (4.8)

It was shown in [24] that the GS terms (4.7) are related to certain $R^2$ supergravity terms [77],

$$\mathcal{L}_{R^2} \sim \langle \varphi \rangle \sqrt{\tilde{g}} \left( \left( y - \frac{x}{4} \right) R^{\mu\nu\rho\sigma} R_{\mu\nu\rho\sigma} + \frac{3}{2} x R_{\mu\nu} \mu^\nu R_{\rho\sigma}^{\rho\sigma} \right).$$

(4.9)

Specializing to a conformally flat background and using results from [75], this shows that the leading four-dilaton interaction (4.1) is determined by the GS coefficients $x$ and $y$,

$$\mathcal{L}_{R^2} \quad \xrightarrow{\text{leading}} \quad -b \left( \frac{\partial \varphi}{\varphi^3} \right)^4, \quad b \sim y - x.$$ (4.10)

The inequality (4.2) then shows that $y \geq x$. This inequality can only be saturated if the dilaton is a free tensor multiplet, in which case there is no RG flow to begin with. In particular, $\Delta a \sim b^2 \sim (y - x)^2$ vanishes in this case [24].
4.2 The $c_i$ conformal anomalies on the tensor branch

We will now use the tensor branch to argue for the anomaly multiplet formulas (1.12) that determine the $c_i$ conformal anomalies in terms of the ’t Hooft anomalies $\alpha, \beta, \gamma, \delta$. We will not provide a complete analysis of these anomaly multiplet relations on the tensor branch, which would require the dilaton effective action coupled to background supergravity fields up to six-derivative order. Instead, we will make the plausible assumption that all six-derivative terms responsible for anomaly matching in the dilaton effective action arise from the completion of four-derivative GS terms and their superpartners. (This assumption was explicitly demonstrated in [24] for the six-derivative terms associated with the $a$ conformal anomaly.) We also postulate that the $c_i$ anomalies obey linear anomaly multiplet relations of the form

$$ c_i = p_i \alpha + q_i \beta + r_i \gamma + s_i \delta $$  \hspace{1cm} (4.11) 

Using (4.8), it follows that the change in these anomalies under the RG flow onto the tensor branch is

$$ \Delta c_i \sim p_i x^2 + 2q_i xy + r_i y^2. $$  \hspace{1cm} (4.12) 

At the special locus $x = y$, the dilaton is free and there is no non-trivial RG flow, so that all $\Delta c_i$ must vanish. It follows that the quadratic polynomials in (4.12) must factor as $\Delta c_i = (y - x)(u_i x + v_i y)$ (recall that this is the case for $\Delta a \sim (y - x)^2$), so that

$$ p_i + 2q_i + r_i = 0. $$  \hspace{1cm} (4.13) 

We can use these linear relations to reduce the number of unknown coefficients in (4.11) from four to three for each $c_i$. Ideally, these coefficients should be derived by constructing the full anomaly multiplet, but we can also determine them by comparing to the free $\mathcal{N} = (1, 0)$ hyper- and tensor multiplets, as well as to the interacting $\mathcal{N} = (2, 0)$ theories. As was explained in section 1.3, this set of reliable unitary examples allows us to fix three of the four coefficients in (4.11). Together with (4.13), this allows us to fix the anomaly multiplet relations for the $c_i$ conformal anomalies in (1.12) while avoiding the non-unitary examples considered in [32, 33].

4.3 Flavor conformal anomalies on the tensor branch

In four dimensional SCFTs, the flavor-current two-point function coefficient $\tau_F$ is determined by the ’t Hooft triangle anomaly of two flavor currents and one $R$-current. This follows from the $d = 4$ multiplet of anomalies in the presence of background supergravity and flavor gauge fields [23]. We anticipate that a similar relation exists for six-dimensional SCFTs, which should relate the flavor-current two-point function coefficient $\tau_F$ to ’t Hooft anomalies involving background supergravity and flavor gauge fields. Since $\tau_F$ scales quadratically with the charges (e.g. in free field theory), such a putative relation must involve a mixed ’t Hooft anomaly with two flavor background gauge fields. The remaining two background fields can either be SU(2)$_R$ or gravity backgrounds, i.e. we consider mixed flavor-SU(2)$_R$ and flavor-diffeomorphism anomalies. We therefore postulate a linear relation between $\tau_F$ and the ’t Hooft anomaly coefficients $\alpha_{F2R2}$ and $\alpha_{F2T2}$ in the anomaly...
Table 3. Some conformal and 't Hooft anomalies related to flavor symmetries. For the (2,0) theories, the flavor symmetry is SU(2)_F \subset Sp(4)_R, which is related to SU(2)_R \subset Sp(4)_R by a Weyl reflection, whence \( \tau_F = \tau^R_1 = c_3 \) (see the discussion below (1.9)).

8-form polynomial,

\[
I_8 \supset \frac{1}{4!} (\alpha_{F^2R^2} c_2(F) c_2(R) + \alpha_{F^2T^2} c_2(F) p_1(T)).
\]  

(4.14)

Recall from the discussion above (2.6) that we normalize \( \tau_F \) so that a free \( N = (2,0) \) tensor multiplet contributes has \( \tau^{Sp(4)}_2 = 1 \). In this normalization, the \( \tau_2 \) conformal anomaly and the 't Hooft anomalies in (4.14) for some known examples are summarized in table 3. The examples in table 3 are sufficient to determine the proposed linear relation between \( \tau_F \) and \( \alpha_{F^2R^2}, \alpha_{F^2T^2} \),

\[
\tau_F = 2\alpha_{F^2T^2} - 2\alpha_{F^2R^2}.
\]  

(4.15)

This is the relation in (1.14).

We can now subject the proposed formula (4.15) to a stringent consistency check by considering an RG flow onto the tensor branch, under which

\[
\Delta \tau_F = 2\Delta \alpha_{F^2T^2} - 2\Delta \alpha_{F^2R^2}.
\]  

(4.16)

The anomaly mismatches \( \Delta \alpha_{F^2T^2} \) and \( \Delta \alpha_{F^2R^2} \) are accounted for by the GS terms for supergravity background fields in (4.7), in conjunction with the flavor GS term (4.5),

\[
\mathcal{L}_{GS} \sim B \wedge (xc_2(R) + yp_1(T) + n_F c_2(F)).
\]  

(4.17)

This leads to 't Hooft anomaly matching contributions beyond (4.8),

\[
\Delta \alpha_{F^2T^2} \sim n_F y, \quad \Delta \alpha_{F^2R^2} \sim n_F x, \quad \Delta \alpha_{F^2T^2} \sim n^2_F.
\]  

(4.18)

with the same overall proportionality factor as in (4.8). Substituting into (4.16), we find that

\[
\Delta \tau_F = 2(\Delta \alpha_{F^2T^2} - \Delta \alpha_{F^2R^2}) \sim 2n_F (y - x).
\]  

(4.19)

This is indeed proportional to \( b \sim y - x \), and trivializes as expected when \( x = y \).
5 Examples

5.1 $\mathcal{N} = (2, 0)$ theories

These theories have an $\text{Sp}(4)_R$ symmetry. Thinking of them in $\mathcal{N} = (1, 0)$ language, it is natural to focus on its $\text{SU}(2)_F \times \text{SU}(2)_R$ subgroup, with $\text{SU}(2)_F$ a flavor symmetry. In our normalization, the conformal anomalies of the interacting $\mathcal{N} = (2, 0)$ theory based on an ADE lie algebra $\mathfrak{g}$ are given by

$$a_{\mathfrak{g}} = \frac{16}{7} h_{\mathfrak{g}}^+ d_{\mathfrak{g}} + r_{\mathfrak{g}}, \quad c_{\mathfrak{g}, i} = \tau_F = \tau_{1R} = 4 h_{\mathfrak{g}}^+ d_{\mathfrak{g}} + r_{\mathfrak{g}}.$$ (5.1)

Consider a rank-one tensor branch of the type $\mathfrak{g}$ theory, associated with the adjoint breaking pattern $\mathfrak{g} \to \mathfrak{h} + \mathfrak{u}(1)$. The apparent change in the anomaly polynomial is

$$4! \Delta I_8 = \Delta k p_2(\text{Sp}(4)_R) \implies \Delta (c_2(L) - c_2(R))^2, \quad \Delta k \equiv k(\mathfrak{g}) - k(\mathfrak{h}), \quad k(\mathfrak{g}) \equiv h_{\mathfrak{g}}^+ d_{\mathfrak{g}}.$$ (5.2)

This requires GS anomaly matching terms (4.17), with $y = 0$ and $x = n_F \sim -\sqrt{\Delta k/6}$. The simplest example in this class occurs for $\mathfrak{g} = \mathfrak{a}_1$ and $\mathfrak{h}$ trivial, so that $\Delta k/6 = 1$. The interacting $\mathfrak{a}_1$ SCFT at the origin has $c_i = \tau_F = \tau_{1R}^R = 25$ and $a = \frac{103}{7}$. This theory was explored using numerical bootstrap techniques in [78].

5.2 Small $E_8$ instanton SCFTs

We can apply our general formulas to determine the conformal anomalies of the $\mathcal{N} = (1, 0)$ SCFTs $\mathcal{E}[N]$ that describe $N$ small $E_8$ instantons in string theory, or alternatively $N$ M5 branes probing an end-of-the-world M9 brane in M-theory. These theories have an $\text{SU}(2)_F \times E_8$ flavor symmetry. Aspects of the corresponding flavor-current correlators were discussed in [49, 79]. Note that our definition of the $\mathcal{E}[N]$ theory includes the free, decoupled hypermultiplet describing overall translations of the $N$ M5 branes in the four transverse directions.

The anomaly polynomial of the $\mathcal{E}[N]$ SCFT was found in [16],

$$\mathcal{I}_{\mathcal{E}[N]} = \frac{N^3}{6} \chi_4^2 + \frac{1}{2} N^2 \chi_4 I_4 + N \left( \frac{1}{2} I_4^2 - I_8 \right).$$ (5.3)

where $\chi_4 \equiv c_2(F) - c_2(R)$ and

$$I_4 \equiv \frac{1}{4} \left( -2 c_2(R) - 2 c_2(F) + p_1(T) \right) + c_2(E_8),$$ (5.4)

$$I_8 \equiv \frac{1}{48} \left( \chi_4^2 + p_2(T) - \frac{1}{4} \left( -2 c_2(R) - 2 c_2(F) - p_1(T) \right)^2 \right).$$ (5.5)

As mentioned in [16], the anomaly polynomial (5.3) exhibits an interesting behavior under the combined transformation $N \to -N$ and $\text{SU}(2)_F \leftrightarrow \text{SU}(2)_R$, which takes $\mathcal{I}_{\mathcal{E}[N]} \to -\mathcal{I}_{\mathcal{E}[N]}$. This was interpreted as exchanging branes with anti-branes, and $\mathcal{N} = (1, 0)$ with

\footnote{The anomaly matching of the full $\text{Sp}(4)_R$ symmetry is more involved and requires the Hopf-Wess-Zumino term of [21].}
$\mathcal{N} = (0, 1)$. We will choose $N > 0$, so that SU(2)$_R$ is the $\mathcal{N} = (1, 0)$ R-symmetry, while SU(2)$_F$ is a flavor symmetry.

Comparing with (1.10), the anomaly polynomial (5.3) gives

$$
\alpha = N(4N^2 + 6N + 3), \quad \beta = -\frac{N}{2}(6N + 5), \quad \gamma = \frac{7N}{8}, \quad \delta = -\frac{N}{2}.
$$

(5.6)

Substituting into (1.11) and (1.12) leads to the following $a$ and $c_i$ conformal anomalies,

$$
a = \frac{64}{7} N^3 + \frac{144}{7} N^2 + \frac{99}{7} N, \quad c_1 = 16N^3 + 38N^2 + 27N, \quad c_2 = 16N^3 + 34N^2 + 21N, \quad c_3 = 16N^3 + 42N^2 + 33N.
$$

(5.7)

To $O(N^3)$, these anomalies agree with those obtained from a naive $Z_2$ orbifold of the $a_{N-1}$ $\mathcal{N} = (2, 0)$ theory, as expected from the M5 brane construction of the $E[N]$ theory. Note however that the $c_i$ anomalies in (5.7) already differ at $O(N^2)$.

As was already stated above, the $E[N]$ SCFTs have an SU(2)$_F$ flavor symmetry. The associated ’t Hooft anomalies can be extracted from the anomaly polynomial (5.3), e.g.,

$$
\alpha_{F^2T^2} = 3N^2 - \frac{5}{2} N, \quad \alpha_{F^2R^2} = -8N^3 + 8N.
$$

(5.8)

Substituting into (1.14) gives the SU(2)$_F$ two-point function coefficient,

$$
\tau_F = 16N^3 + 6N^2 - 21N.
$$

(5.9)

For comparison, the SU(2)$_R$ current two-point function coefficient is given by (see (1.9))

$$
\tau^R_1 = c_3 = 16N^3 + 42N^2 + 22N.
$$

(5.10)

The fact that $\tau_F$ and $\tau^R_1$ coincide at leading $O(N^3)$ is again consistent with a naive $Z_2$ orbifold of the $a_{N-1}$ $\mathcal{N} = (2, 0)$ theory, and again the two expressions differ at $O(N^2)$. Note that (5.9) and (5.10) are not simply related by the $N \rightarrow -N$ transformation mentioned above. This is not a contradiction, since it need not be the case that replacing $N \rightarrow -N$ exchanges SU(2)$_F$ and SU(2)$_R$ for all purposes.\footnote{An analogous phenomenon occurs in certain $d = 4$, $\mathcal{N} = 2$ SCFTs [80] with similar brane realizations.} As a check of (5.9), note that when $N = 1$ the SU(2)$_F$ flavor symmetry only acts on the free, decoupled hypermultiplet associated with M5 brane motion in the transverse directions. Indeed substituting $N = 1$ in (5.9) gives $\tau_F = 1$, as expected for a free hypermultiplet.

The anomaly coefficients in (5.3) that involve the $E_8$ background gauge field are

$$
\alpha_{E_8^2R^2} = -12(N^2 + N), \quad \alpha_{E_8^2T^2} = 6N.
$$

(5.11)

Substituting into (1.14) then gives the $E_8$ two-point function coefficient,

$$
\tau_{E_8} = 12(2N^2 + 3N).
$$

(5.12)

This result has already appeared in [49].
Finally, let us consider a tensor-branch deformation corresponding to moving one M5 brane away from the M9 brane and the other \( N - 1 \) M5 branes, so that \( \mathcal{E}[N] \rightarrow \mathcal{E}[N-1] + \mathcal{E}[1] \). The anomaly mismatch is accounted for by a GS mechanism [18],

\[
\Delta I_8 = \frac{1}{2} X_4^2, \quad X_4 = (N - 1)c_2(F) - Nc_2(R) + \frac{1}{4} p_1(T) + c_2(E_8). \tag{5.13}
\]

Since the GS term (4.7) is proportional to \( B \wedge I_4 \), we conclude that

\[
x \sim -N, \quad y \sim \frac{1}{4}. \tag{5.14}
\]

Using (5.9), (5.10), and (5.12), we can evaluate

\[
\Delta \tau_1^R = \Delta c_3 = 48 \left( N + \frac{1}{2} \right) \left( N + \frac{1}{4} \right), \quad \Delta \tau_F = 48(N-1) \left( N + \frac{1}{4} \right), \quad \Delta \tau_{E_8} = 48 \left( N + \frac{1}{4} \right). \tag{5.15}
\]

Since it follows from (5.14) that \( N + \frac{1}{4} \sim y - x \), it is indeed true that all quantities in (5.15) are proportional to \( y - x \), as we argued on general grounds.

5.3 Holographic examples

Consider \( d = 6 \) SCFTs with AdS\(_7\) holographic duals; see e.g. [81] and references therein for examples. The AdS\(_{d+1}\)/CFT\(_d\) dictionary relates the flavor-current two-point function coefficient \( C_F \) to \( L^{d-3} g_{F_F}^{-2} \) [82], where \( L \) is the AdS\(_{d+1}\) length scale, and \( g_{F_F}^{-2} \) is the coefficient of the bulk Yang-Mills term corresponding to the flavor symmetry in the boundary CFT, \( S_{bulk} \supset \int \left( -\frac{1}{4} g_{F_F}^{-2} \right) \text{Tr} \: F_F \wedge \ast F_F \). In our conventions and \( d = 6 \) we have

\[
\tau_1^F = \frac{5}{3} 2^5 L^3 g_{F_F}^{-2}. \tag{5.16}
\]

The fact that \( \tau_2^F = \rho^F = 0 \) in SCFTs should follow from an analysis of AdS\(_7\) supergravity. Moreover, the relation (1.14) implies that the \( g_{F_F}^{-2} \) Yang-Mills coefficient of the AdS\(_7\) supergravity theory is related to the bulk Chern-Simons terms responsible for the \( \alpha_{F_2 T_2} \) and \( \alpha_{F^2 R^2} \) ’t Hooft anomalies on the boundary. See [83] for some related comments.
