(Dated: March 29, 2022)

The exotic $\beta$-delayed proton emission is calculated in $^{11}$Be from first principles using chiral two- and three-nucleon forces. To investigate the unexpectedly-large branching ratio measured in [PRL 123, 082501 (2019)] we calculate the proposed $\{1/2^+, 1/2\}$ proton resonance in $^{11}$B using the no-core shell model with continuum. This calculation helps to address whether this enhancement is caused by unknown dark decay modes or an unobserved proton resonance. We report a branching ratio of $b_p = (1.3 \pm 0.5) \times 10^{-6}$, suggesting that its unexpectedly-large value is caused by an unobserved proton resonance in $^{11}$B.

**I. INTRODUCTION**

Nuclear $\beta$-decay is well-recognized as a process sensitive to nuclear structure [1]. When considering neutron-rich nuclei, a particularly interesting $\beta$-decay reaction known as $\beta$-delayed particle emission is possible [2]. Specifically, $\beta$-delayed proton emission is a rare process in which the parent nucleus undergoes $\beta$-decay into a proton-unbound state from which the proton is emitted. Due to energy conservation, this exotic process is forbidden unless $S_n < (m_n - m_p - m_e)c^2 \approx 782$ keV where $S_n$ is the neutron separation energy and $m_n$, $m_p$, and $m_e$ are the neutron, proton, and electron rest masses, respectively [2]. The $^{11}$Be nucleus is a halo nucleus with a neutron separation energy of 0.5016 MeV, making it an ideal candidate for such a decay. It has been suggested that this particular process can shed some light on the neutron lifetime puzzle in that it could reveal an exotic dark-decay mode [3].

The $\beta$ decay of the ground state of $^{11}$Be into the continuum was originally calculated using a cluster expansion resulting in a small branching ratio, $b_p = 3.0 \times 10^{-8}$ [2]. This small branching suggested it was extremely rare compared to other $\beta$-decay branches such as to the ground state ($b_p = 0.547$) or to one of the many excited states in $^{13}$B [e.g. $b_p = 0.314$ to the $1/2^+_1$ excited state, $b_p = 0.0647$ to the $1/2^+_1$ excited state etc.] [4]. To further investigate this $\beta$-delayed proton emission, Risager et al. indirectly measured the decay of $^{11}$Be to $^{10}$Be [5]. This experiment revealed a large branching ratio of $b_p = 8.3(9) \times 10^{-6}$, two orders of magnitude larger than the previous theoretical calculation. Thus, two possible explanations were proposed for this discrepancy. Either the halo neutron decays to an unobserved proton resonance in $^{11}$B, or there are other unobserved, exotic neutron decay modes such as dark decay modes [5].

Seven years later, in 2019, Ayyad et al. directly observed the $^{11}$Be $\beta$-delayed proton emission in an experiment performed at TRIUMF. The corresponding experimental branching ratio of $b_p = 1.3(3) \times 10^{-5}$ is consistent with the large branching ratio observed in the previous indirect experiment [6]. This branching ratio equates to $B(GT) = 5.5^{+3.3}_{-3.3}$ which falls under the theoretical limit of 3 for the $\beta$-decay of a free neutron within one standard deviation [7]. Furthermore, because this experiment involved direct detection, the ejected proton distribution was used to locate the possible proton resonance in $^{11}$B. The resonance was found to have spin 1/2 (or 3/2), positive parity, and isospin 1/2 with an excitation energy of 197 keV. This measurement supported the first explanation: the existence of an unobserved resonance in $^{11}$B.

There have been several theoretical investigations of the proposed $^{10}$Be+$p$ resonance with differing results. The authors of Ref. [8], using a shell model embedded in the continuum (SMEC), conclude that the branching ratio of $\beta$-delayed $\alpha$ emission, the predicted resonance width, and the observed $\beta$-delayed proton emission in Ref. [6] can not be reconciled within their calculations. Another shell model analysis of this system claims that the experimentally observed branching ratio is impossible to explain [3]. The halo effective field theory analysis in Ref. [9] supports the existence of the proposed proton resonance.

In this work, we address the $\beta$-delayed proton emission in $^{11}$Be from first principles using the no-core shell model with continuum (NCSMC) [10–13]. First, we carry out $p^{+10}$Be scattering calculations to search for the proposed resonance in $^{11}$B. Second, we develop the framework to consistently compute $\beta$-decay matrix elements within the NCSMC approach and evaluate the $\beta$-decay branching ratio from the ground state of $^{11}$Be to the $p^{+10}$Be channel. The NCSMC is well-suited to describe this particular decay since it not only accurately describes the structure of light nuclei, but properly profiles the continuum in the low-energy regime. In Sect. II, we briefly introduce the NCSMC and the microscopic Hamiltonian adopted in the present study. Main results are presented in Sect. III and conclusions are given in Sect. IV. Details of the calculation of the NCSMC formalism for the calculation of $\beta$-decay matrix elements are given in Appendix A.

**II. THEORY**

The $\beta$-decay operator of the $J^p=1/2^+, T=3/2$ ground state of $^{11}$Be to a $J^p=1/2^+, T=1/2$ proton-unbound
$p+^{10}\text{Be}$ state is purely driven by the (reduced) matrix elements of the Gamow-Teller (GT) operator due to the change in isospin [1]:

$$B(\text{GT}) = \frac{1}{2} \left| \left\langle \Psi_{1/2}^{\pi=1} | \hat{G}\pi \Psi_{1/2}^{\pi=3} \right\rangle \right|^2.$$  \hspace{1cm} (1)

Here we consider the leading order GT operator

$$\hat{G}\pi = \sum A \hat{r}_i \hat{\pi}_i^+,,$$

where $\hat{\pi}_i$ is the single-particle Pauli operator and $\hat{\pi}_i^+$ is the single-particle isospin-raising operator [1]. The evaluation of Eq. (1) requires a framework such as the NCSM where bound and scattering wave functions are consistently calculated. The ansatz for the NCSMC initial(final) state is a generalized cluster expansion [13]

$$|\Psi_A^{J,T}\rangle = \sum_{\lambda} c_{\lambda}^{J,T} |A\lambda J^{\pi}T\rangle + \sum_{\nu} \int dr r^2 drr^{J,T}(r) \hat{A}_{\nu} |\Phi_{\nu}^{J,T}\rangle.$$  \hspace{1cm} (2)

The first term is an expansion over no-core shell model (NCSM) [14] eigenstates of the aggregate system $|AJ^{\pi}T\rangle$ (either $^{11}\text{Be}$ in the initial state or $^{11}\text{B}$ in the final state) calculated in a many-body harmonic oscillator basis. The second term is an expansion over microscopic cluster channels $\hat{A}_{\nu} |\Phi_{\nu}^{J,T}\rangle$ which describe the clusters (either $^{10}\text{Be}+n$ in the initial state or $^{10}\text{Be}+p$ in the final state) in relative motion:

$$|\Phi_{\nu}^{J,T}\rangle = \left[ (|^{10}\text{Be} \alpha_1 T_1^+ T_1\rangle |N \frac{1}{2} \pi \frac{1}{2}\rangle)^{\lambda^{J,T}} \langle \lambda | Y_{\ell}(\hat{r}_{10,1}) \right]^{(J,T)} \times \frac{\delta(r-r_{10,1})}{r_{10,1}},$$  \hspace{1cm} (3)

where $|^{10}\text{Be} \alpha_1 T_1^+ T_1\rangle$ and $|N \frac{1}{2} \pi \frac{1}{2}\rangle$ are the eigenstates of $^{10}\text{Be}$ and $N$, respectively, with $N$ representing $n$ for the initial state ($^{11}\text{Be}$) and $p$ for the final state ($^{11}\text{B}$). The cluster channels enable the description of scattering states as well as weakly bound extended (halo) states in the NCSMC. The $^{10}\text{Be}$ eigenstate (also calculated within the NCSM) has angular momentum $I_1$, parity $\pi_1$, isospin $T_1$, and energy label $\alpha_1$. Here $r$ denotes the distance between the clusters and $\nu$ is a collective index of the relevant quantum numbers. The coefficients $c_{\lambda}^{J,T}$ and relative-motion amplitudes $\gamma_{\nu}^{J,T}(r)$ are found by solving a two-component, generalized Bloch Schrödinger equations derived in detail in Ref. [13]. The $\hat{A}_{\nu}$ term is the inter-cluster antisymmetrizer:

$$\hat{A}_{\nu} = \sqrt{\frac{(A-1)!}{A!}} \left( 1 + \sum_{\rho \neq \nu} (-1)^{\rho} \rho P \right),$$

where the sum runs over all possible permutations of nucleons $P$ (different from the identical one) that can be carried out between the target cluster and projectile, and $p$ is the number of interchanges characterizing them. The resulting NCSMC equations are solved using the coupled-channel $\text{R-matrix}$ method on a Lagrange mesh [11, 15].

We start from a microscopic Hamiltonian including the nucleon-nucleon $(NN)$ chiral interaction at next-to-next-to-next-to-leading order ($^N\text{LO}$) with a cut-off $\Lambda=500$ MeV developed by Entem et al [16, 17], denoted as $NN-N^4\text{LO}(500)$. In addition to the two-body interaction, we include a three-body ($3N$) interaction at next-to-next-to-leading order ($^N\text{LO}$) with simultaneous local and nonlocal regularization [18–21]. The whole interaction (two- and three-body) will be referred to as $NN-N^4\text{LO}(500)+3N_{\text{int}}$. A faster convergence of our NCSMC calculations is obtained by softening the Hamiltonian through the similarity renormalization group (SRG) technique [22–25]. The SRG unitary transformation induces many-body forces that we include up to the three-body level. Four- and higher-body induced terms are small at the $\lambda_{\text{SRG}}=1.8$ fm$^{-2}$ resolution scale used in the present calculations [26]. Concerning the frequency of the underlying HO basis, we choose $\hbar\Omega = 18$ MeV for which the ground state energies of the investigated nuclei present minimum. For technical reasons, we are not able to reach basis sizes beyond $N_{\text{max}}=7$ for $^{11}\text{B}$ and $^{11}\text{Be}$.

We note that the present calculations are the first application of the NCSMC approach to the description of $\beta$-decay transitions. While the present calculation is implemented solely for the GT operator, the formalism is also valid for the Fermi (as well as the spin part of $M_1$) one-body operator. We are able to calculate the relevant matrix elements without approximations (as opposed to the radiative capture calculations in, e.g., Ref. [26]) and evaluate the transition kernels (i.e., matrix elements entering the integrals in Eq. (A1)) using a similar technique applied to calculate Hamiltonian interaction/norm kernels. See Appendix A for the full derivation of the NCSMC GT matrix element utilizing second quantization.

III. RESULTS

A. NCSMC calculations for $^{11}\text{Be}$ and $^{11}\text{B}$

We start by performing NCSM calculations for $^{10,11}\text{Be}$ and $^{11}\text{B}$. The obtained eigenvalues and eigenvectors serve as input for the NCSMC. For the expansion in Eq. (2), we used the $^{10}\text{Be}$ $0^+$ ground state and the first excited $2^+$ state, the lowest 12 (10) positive (negative) parity eigenstates for $^{11}\text{Be}$, and 20 (12) positive (negative) eigenstates for $^{11}\text{B}$ with $J$ ranging from 1/2 to 11/2. The resulting NCSMC energy spectra of $^{11}\text{Be}$ and $^{11}\text{B}$ are shown in Figs. 1 and 2, respectively. We present only states corresponding to experimentally bound states with respect to the $^{10}\text{Be}+p$ (for $^{11}\text{B}$) and $^{10}\text{Be}+n$ (for $^{11}\text{Be}$)
threshold.

The low-lying level ordering in \(^{11}\text{Be}\) is important because the energies of the \(1/2^+\) and \(1/2^-\) states are inverted compared to what would be expected from a standard shell-model picture. Our chosen interaction reproduces this parity inversion in the resulting NCSMC levels, as can be seen in Fig. 1. In previous NCSMC calculations using different interactions, the parity inversion could be reproduced with the non-local \(N^2\text{LO}_{\text{sat}}\) interaction [27] but not using interactions with local \(3N\) [28]. Since the \(NN-N^4\text{LO}(500)+3N_{\text{nl}}\) interaction reproduces this peculiarity of \(^{11}\text{Be}\), we feel that (i) the non-locality of the \(3N\) interaction is an important feature for the description of exotic nuclei (i.e. it leads to a better reproduction of the extended nuclear density) and (ii) the selected interaction is appropriate for calculating the \(^{11}\text{Be}\) \(\beta\) decay. The present description is still showing discrepancies with data as the \(1/2^+\) state is less bound than in experiment and the experimentally very weakly bound \(1/2^-\) state is obtained just above the \(^{10}\text{Be}+n\) threshold.

The lowest negative-parity \(^{11}\text{Be}\) levels are well reproduced in our calculations with an under-prediction of the splitting between the \(3/2^-\) ground state and the \(1/2^-\) first excited state, indicating a weaker spin-orbit strength of the employed interaction. The lowest \(5/2^-\) and \(7/2^-\) as well as \(3/2_2^+\) and \(5/2_2^-\) states match well the experimental energies. The experimental \(3/2_3^-\) state at 8.56 MeV (not shown in Fig. 2) with a pronounced \(\alpha\)-cluster structure is, however, overpredicted in the present NCSMC calculations [29]. Similarly, the lowest positive-parity states appear more than 2.5 MeV too high. This is in part a consequence of the missing \(^7\text{Li}+\alpha\) mass partition in the calculations that we were not able to include for technical reasons. The \(^7\text{Li}+\alpha\) threshold appears experimentally 2.56 MeV below the \(^{10}\text{Be}+p\) threshold. The focus of this work is in particular on the \(T=1/2\) \(1/2^+\) and \(3/2^+\) states in \(^{11}\text{Be}\). As seen in Fig. 2, we obtain one \(T=1/2\) \(1/2^+\) bound state and the lowest \(3/2^+\) state is just above the \(^{10}\text{Be}+p\) threshold.

In addition to bound-state energy spectra, the NCSMC provides the low-energy phase shifts and eigenphase shifts for the \(^{10}\text{Be}+p\) channel, see Figs. 3 and 4, respectively. To show the effect of increasing the basis size, both the \(N_{\text{max}}=5\) and \(N_{\text{max}}=7\) results are presented in Fig. 3(a) and Fig. 3(b), respectively, and similarly for the eigenphase shifts in Fig. 4. The \(\{1/2^-,3/2\}\) and \(\{1/2^+,3/2\}\) phase shifts, isobaric analogues of the two bound states in \(^{11}\text{Be}\), are plotted to emphasize the parity inversion discussed in the previous paragraph. Both the \(N_{\text{max}}=5\) and \(N_{\text{max}}=7\) calculations reproduce the parity inversion in that the \(\{1/2^+,3/2\}\) resonance is lower in energy than the \(\{1/2^-,3/2\}\) resonance. The separation between these two resonances is more pronounced in the more converged result of \(N_{\text{max}}=7\) (see Fig. 3(b)).

Shifting focus to the \(\{1/2^+,1/2\}\) phase shifts, two resonances are present - one broad and one sharp. Thus, the NCSMC supports the existence of a \(\{1/2^+,1/2\}\) resonance in the \(^{10}\text{Be}+p\) system. However, the energy of either resonance is higher than the experimental prediction of 197 keV. Furthermore, it is unclear which resonance should correspond to the experimental prediction.
FIG. 3. NCSMC-calculated $^{10}\text{Be}+p$ diagonal phase shifts. The solid lines correspond to the $^{2}S_{1/2}$ (or $^{2}P_{1/2}$) channels while the dashed and dotted curves correspond to the $^{4}D_{1/2}$ and $^{6}D_{1/2}$ channels, respectively. The vertical dashed line indicates the experimentally-predicted location of the $(1/2^+,1/2)$ resonance at 197 keV. (a) NCSMC-calculated phase shifts using $N_{\text{max}}=5$ basis size. (b) NCSMC-calculated phase shifts using $N_{\text{max}}=7$ basis size. (c) Phenomenologically adjusted, NCSMC$_{\text{pheno}}$ phase shifts such that the $(1/2^+,1/2)$ resonance coincides with the experimentally-predicted resonance at 197 keV. The $(3/2^+,1/2)$ resonance is the result of shifting the degenerate states to the corresponding experimental levels (see Fig. 2). See the text for details. $E_{\text{c.m.}}$ is the kinetic energy of $^{10}\text{Be}+p$ in the center-of-mass frame.

To gain insight in the structure of the $1/2^+$ states, we follow Ref. [30] to calculate the overlap between the corresponding NCSM $^{11}\text{Be}$ states and the $^{10}\text{Be}$ ground state, $^{10}\text{B}$ $(1^+,0)$ excited states, and the $^7\text{Li}$ ground state (see Table I). The first $1/2^+$ state with the largest overlap with the $^{10}\text{Be}$ ground state corresponds to the bound state shown in Fig. 2 while the second and third $1/2^+$ states, corresponding to the two $(1/2^+,1/2)$ resonances in Fig. 3, have comparably low overlaps. While these proton spectroscopic factors do not distinguish between the two resonances, the large $1/2^+_2$ $^{10}\text{B}$ overlap indicates that its corresponding NCSMC resonance contains significant single-neutron content. From this, it is clear that the sharp resonance is caused by the lack of $^{10}\text{B}$ $1^+$ channels and would be broadened by their inclusion in the NCSM calculation. With the sharp resonance classified, the broad resonance must therefore correspond to the $1/2^+_3$ NCSM state and be the candidate for the experimentally-measured proton resonance.

B. Phenomenologically adjusted NCSMC

With the resonance identified, the next step is to calculate the branching ratio for the $\beta$-decay from the $^{11}\text{Be}$ ground state to the $^{11}\text{B}$ proton resonance. In order to better evaluate how well this resonance explains the experimentally observed branching ratio, we introduce a phenomenological shift to the NCSMC calculation (see, e.g., Ref. [28]) resulting in the calculated resonance lying at 197 keV, see Fig. 3(c). This approach, dubbed NCSMC$_{\text{pheno}}$, proceeds by using the $^{10}\text{Be}$, $^{11}\text{B}$, and $^{11}\text{Be}$ NCSM eigenenergies as adjustable parameters in the NC-
TABLE I. NCSM spectroscopic factors calculated from the overlap between select \(^{11}\)B states and \(^{10}\)Be, \(^{10}\)B, and \(^{7}\)Li states. The first column displays the \(J^e\) of each considered \(T = 1/2\) \(^{11}\)B state. Spectroscopic factors of the ground states of \(^{10}\)B and \(^{10}\)Be and the first two \((1^+, 0)\) excited states of \(^{10}\)B are presented.

| \(J^e\) | \(S^{(11\text{B}\rightarrow 10\text{Be})}\) | \(S^{(11\text{B}\rightarrow 10\text{B})}\) | \(S^{(11\text{B}\rightarrow 7\text{Li})}\) |
|--------|----------------|----------------|----------------|
| \(1/2^+\) | 0.276 | 0.250 | 2 \times 10^{-4} | 0.218 |
| \(1/2^+\) | 0.0325 | 0.171 | 0.562 | 0.002 |
| \(1/2^+\) | 0.067 | 0.231 | 0.188 | 0.011 |
| \(3/2^+\) | 0.079 | 6 \times 10^{-4} | 0.215 | 0.009 |
| \(3/2^-\) | 4 \times 10^{-4} | 0.581 | 0.002 | 0.012 |
| \(3/2^-\) | 6 \times 10^{-4} | 0.011 | 0.006 | 0.021 |
| \(3/2^+\) | 0.067 | 0.034 | 0.35 | 0.006 |

C. \(^{11}\)Be \(\beta\) decay

We first calculate \(B(GT)\) for the \(\beta\)-decay from the \(^{11}\)Be ground state to the first bound \((1/2^+, 1/2)\) state in \(^{11}\)B. This level is shifted to its experimental value as well, see Fig. 2. The results are shown in Table II. Also shown in Table II is the \(B(GT)\) calculated for the \(\beta\)-decay to the three bound \((3/2^+, 1/2)\) states. The third bound \((3/2^+, 1/2)\) state is a result of phenomenologically shifting the first two levels to their corresponding experimental values. To determine the half-life from \(B(GT)\), we use [1]:

\[
fT_{1/2}^p = \frac{6141}{g_A^2 B(GT)},
\]

where \(g_A = -1.27\) is the GT coupling constant, \(f\) is a phase-space factor determined by the \(Q\)-value of the decay, and \(T_{1/2}^p\) is the half-life of the decay. The half-life of the decay can be used to calculate the corresponding branching ratio using the following expression:

\[
b_p = \frac{T_{1/2}^{11\text{Be}}}{T_{1/2}^p},
\]

where \(T_{1/2}^{11\text{Be}} = 13.8\) s is the half-life of the \(^{11}\)Be nucleus. Using Eqs. (4) and (5), the experimental branching ratios (see Ref. [4]) were converted to the \(B(GT)\) values in Table II. It is clear from Table II that the inclusion of the proton and neutron channels in the NCSMC improves the calculated \(B(GT)\) values over the NCSM results. The transition strength to the \(1/2^+\) state is unexpectedly large compared to the experimental strength. This is indicative of the mixing of strength between the bound \(1/2^+\) state and the resonance in question. It is also worth noting that the overlap between the \(1/2^+\) state and both the \(^7\)Li\(+\alpha\) ground and \(^{10}\)B\(+\)n \((1^+, 0)\) states is significant (see Table I). Thus, the inclusion of these channels in the NCSMC calculation could address this discrepancy.

TABLE II. \(B(GT)\) values from the ground state of \(^{11}\)Be to the specified bound states of \(^{11}\)B. The first column displays the \(J^e\) of each considered \(T = 1/2\) \(^{11}\)B state. The NCSMC\(_{\text{pheno}}\) approach was applied. Both the NCSM and NCSMC\(_{\text{pheno}}\) values were obtained at \(N_{\text{max}} = 7\). Experimental values obtained as branching ratios from Ref. [4] and converted to \(B(GT)\) values (see text).

| \(B(GT)\) | NCSM | NCSMC\(_{\text{pheno}}\) | Expt. |
|---------|------|----------------|------|
| \(1/2^+\) | 0.341 | 0.277 | 0.004 |
| \(3/2^+\) | 0.023 | 0.002 | 0.010 |
| \(3/2^-\) | 2.92 | 0.286 | 0.228 |
| \(3/2^+\) | 0.011 | 7 \times 10^{-5} | -  |
for this process, $B_{GT}(k)$ must be folded with the energy-dependent phase-space factor $f$. Thus, we first transform Eq. (6) to energy-space such that

$$B(GT) = \int_{E_{min}}^{E_{max}} dEB_{GT}(E) ,$$

(7)

where

$$B_{GT}(E) := \frac{4\pi \mu k}{h^2} B_{GT}(k)$$

and $k = \sqrt{2E/\mu}$ with $\mu$ the reduced mass. The energy-dependent $B_{GT}(E)$ is shown in Fig. 5, where it displays a prominent peak at the resonance energy of 197 keV. The sharp peak in $B_{GT}(E)$ is a visual representation of how a resonance can enhance the $\beta$-decay transition rate to the continuum. The $Q$-value at a given energy can be expressed as $Q = Q_0 - E$ where $Q_0 = 0.281$ MeV is the $Q$-value evaluated at the $p^{+10}$Be threshold. The branching ratio of the $\beta$-decay to the resonance can be calculated by combining Eqs. (4), (5), and (7) in the following way:

$$b_p = \frac{T_{1/2}^{11}Be}{6141} \int_{E_{min}}^{E_{max}} dEB_{GT}(E) f(Q_0 - E) .$$

(8)

Using Eq. (8), we integrate $B_{GT}(E)$ over the energy-range shown in Fig. 5 resulting in the values shown in Table III. The NCSMC $B(GT)$ value reported in Table III is calculated as $B(GT) = \int dEB_{GT}(E)$. Although the calculated branching ratio, $b_p = (1.3 \pm 0.5) \times 10^{-6}$, is lower than the two experimental observations [5, 6], it is consistent when taking into account that the non-resonant decay branching ratio calculated in Ref. [2] is two orders of magnitude smaller. The uncertainty is estimated by comparing the NCSMC_{pheno} results using $N_{max} = 5$ and $N_{max} = 7$. To verify that we shifted the correct resonance, we also calculated $B(GT) = 0.0483$ for the transition to the $(1/2^+, 1/2)$ resonance located around 1 MeV in Fig. 3(c). This weak transition strength confirms that we have chosen the correct candidate. We also investigate the sharp $(3/2^+, 1/2)$ resonance in Fig. 3(c) as it was suggested as a candidate for the large branching ratio [6].

While there is a non-negligible overlap between $3/2^+_1$ and $^{10}$Be+\(p\) (see Table I), we calculate that $B(GT) = 0.0013$ for this particular resonance. This is contrary to the large $B(GT)$ empirically calculated for this resonance in Ref [31]. It is also worth nothing that the $\alpha$ spectroscopic factors for the $1/2^+_2$ and $1/2^+_3$ states in Table I are significantly smaller than those calculated in the shell model calculations in Ref. [3]. The smaller spectroscopic factors indicate that the proton decay channel will not have as much competition with the $\alpha$ decay channel as was indicated of Ref. [3]. With these considerations, we conclude that the large observed branching is due to the existence of this $(1/2^+, 1/2)$ $p^{+10}$Be resonance.

IV. CONCLUSIONS

Using the ab initio NCSMC, we investigated the bound energy-levels and low-lying resonances in both \( ^{11}\text{Be} \) and \( ^{11}\text{B} \). The two- and three-body interactions, \( NN\text{-N}^{3}\text{LO}(500)+3\text{Ninf} \), produce realistic energy spectra in both \( ^{11}\text{Be} \) and \( ^{11}\text{B} \). The experimentally-observed parity inversion in \( ^{11}\text{Be} \) is reproduced. We identified two \((1/2^+, 1/2)\) resonances in the p+\(^{10}\text{Be}\) continuum and determined that the broad resonance dominated by the \(1/2^+\) NCSM state is the candidate resonance. The location of the resonance is several MeV higher than the experimentally predicted location of 197 keV although its position decreases dramatically with the increasing basis size. In order to determine if this resonance can explain the large branching ratio observed by experiment, we phenomenologically shifted the NCSMC resonance to 197 keV.

With the resonance determined, we developed the procedure to calculate \( B(GT) \) fully within the NCSMC. Appendix A contains the relevant derivations. We then extended the calculation to the continuum by deriving the necessary expressions to calculate the branching ratio for the decay to a resonance state (in the \( ^{10}\text{Be} \) continuum). The resulting branching ratio for the \( \beta \)-decay to the candidate \((1/2^+, 1/2)\) resonance is \( B(p) = (1.3 \pm 0.5) \times 10^{-6} \). This calculated branching ratio is consistent with both experimental branching ratios reported Ref. [5] and Ref. [6] taking into account that the non-resonant decay branching ratio is two orders of magnitude smaller. Furthermore, we calculate a small \( B(GT) \) for the nearby \((3/2^+, 1/2)\) resonance which further reinforces our conclusions.

The present calculations can be further improved by including the \(^7\text{Li}+\alpha \) and \(^{10}\text{Be}+\pi \) mass partitions. The former would particularly impact the description of the \(1/2^+\) bound state and presumably redistribute some of the \( B(GT) \) strength from the bound state to the \((1/2^+, 1/2)\) resonance. Work in this direction is under way, see Ref. [33] for the latest developments regarding the inclusion of \( \alpha \) clustering in the NCSMC.

Appendix A: Derivation of \( B(GT) \) in the NCSMC

To calculate \( B(GT) \), the reduced matrix element of the GT operator is calculated with NCSMC initial and final states. We derive this reduced matrix element for a general coordinate-independent one-body operator, \( O_{\mu_+}^{(\kappa \tau)} \) with \( \kappa \) and \( \tau \) the spin and isospin rank, respectively, and \( \mu_+ \) the isospin projection, e.g., GT, Fermi, spin part of the M1 operator. The GT operator corresponds to the case where \( \kappa=1,\, \tau=1 \) and \( \mu_+=+1 \). Inserting the form of the NCSMC wave function (Eqs. (2) and (3)) in Eq. (1) leads to four contributions:

\[
\langle \Psi_f^{Jf,T_f, M_f} | \hat{O}_{\mu_+}^{(\kappa \tau)} | \Psi_i^{Ji,T_i, M_i} \rangle = 
\sum_{\lambda_i, \lambda_f} \tilde{c}_{\lambda_f} \bar{c}_{\lambda_i} \langle A \lambda_f J_f T_f M_f | \hat{O}_{\mu_+}^{(\kappa \tau)} | \bar{A} \lambda_i J_i T_i M_i \rangle 
+ \sum_{\lambda_i, \mu_+} \tilde{c}_{\lambda_f} \int_0^\infty dr r^2 \tilde{\chi}_{\lambda_f}(r) \frac{1}{2} 
\times \langle A \lambda_f J_f T_f M_f | \hat{O}_{\mu_+}^{(\kappa \tau)} \bar{A} \lambda_i | \Phi_{\mu r}^{A, J_i, T_i, M_i} \rangle 
+ \sum_{\lambda_i, \mu_+} \bar{c}_{\lambda_i} \int_0^\infty dr r^2 \bar{\chi}_{\lambda_i}(r) \frac{1}{2} 
\times \langle \Phi_{\mu r}^{A, J_i, T_i, M_i} | A \lambda_f J_f T_f M_f | \hat{O}_{\mu_+}^{(\kappa \tau)} \bar{A} \lambda_i \rangle 
+ \sum_{\nu, \mu_+} \int_0^\infty dr' r'^2 \tilde{\chi}_{\nu}(r') \frac{1}{2} \int_0^\infty dr r^2 \tilde{\chi}_{\lambda_f}(r) \frac{1}{2} 
\times \langle \Phi_{\mu r}^{A, J_i, T_i, M_i} | A \lambda_f J_f T_f M_f | \hat{O}_{\mu_+}^{(\kappa \tau)} \bar{A} \lambda_i \rangle 
\equiv (A1) \]

The expansion coefficients \( \tilde{c} \) and \( \tilde{\chi}(r) \) can be related to the expansion (2) and NCSMC norm kernels according to Eqs. (20), (32) and (33) in Ref. [11]. We note that the \( J^T M_T \) quantum number dependence of these coefficients is not displayed to simplify the notation. Similarly, we omit the parity quantum number in most of the states. In the present case, \( A=11 \). We also note that matrix element (A1) is reduced only in spin-space, not isospin-space.

In order to proceed with the derivation, all contributions from localized terms are calculated in a HO basis and then converted to coordinate space with the following relation [34]:

\[
| \Phi_{\mu r}^{J^T M_T} \rangle = \sum_n | \Phi_{\nu n}^{J^T M_T} \rangle R_{nt}(r), \tag{A2}
\]

where \( R_{nt}(r) \) are radial HO functions and

\[
| \Phi_{\nu n}^{J^T M_T} \rangle = \left( \left( ^{10}\text{Be} \right) \begin{pmatrix} \alpha_1 T_1 \end{pmatrix} | N \frac{1}{2^+} \right)^{(sT)} 
\times Y_{\ell}(f_{10.1}) \begin{pmatrix} J^T M_T \end{pmatrix} R_{nt}(r_{10.1}) \tag{A3}
\]

with \( N \) representing \( \pi \) for \(^{11}\text{Be} \) and \( n \) for \(^{11}\text{B} \). See also the discussion in Sect. II.C.1 in Ref. [34].
The process to calculate each of the terms in Eq. (A1) is analogous to the procedure for calculating the norm and Hamiltonian kernels for the NCSMC [13]. The first term in Eq. (A1) involves NCSM matrix elements of $\hat{O}_{\mu r}^{(\kappa \tau)}$ calculated using standard second-quantization techniques. The second and third terms are analogous to the coupling kernels when solving the NCSMC Hamiltonian equations [13]. In order to continue, we represent the operator in a second-quantized form:

$$\hat{O}_{\mu r}^{(\kappa \tau)} = \left(\frac{-1}{\hbar}\right) \sum \left\langle j_\alpha \frac{1}{2} m_{t_\alpha} \middle| \hat{O}_{\mu r}^{(\kappa \tau)} \middle| j_\beta \frac{1}{2} m_{t_\beta} \right\rangle \times \hat{a}_{j_\alpha m_{t_\alpha} \frac{1}{2} m_{t_\alpha}} \hat{a}_{j_\beta m_{t_\beta} \frac{1}{2} m_{t_\beta}} \left\langle j_\alpha m_a j_\beta m_b | \kappa \mu \right\rangle,$$

with $\hat{a}_{jm \frac{1}{2} m t} = (-1)^{j-m} a_{jm \frac{1}{2} m t}$. To expand this term, we also represent the cluster wave function in a second-quantized form (see Sect. II.D.2 of Ref. [34] and Sect. II.A of Ref. [35]):

$$\hat{A}_\nu |\Phi_{\nu n}^{J_1 M_1 T_1 M_{T_1}}\rangle_{SD} = \sum (-1)^{j_1 + j_2 + j_3} \left\langle I_1 \ell_1 \ell_2 \ell_3 \right| I_1 \ell_1 \ell_2 \ell_3 \rangle \times \langle I_1 M_1 j m | J_1 M_1 \rangle \langle T_1 M_{T_1} \frac{1}{2} m t | T_1 M_{T_1} \rangle \times \hat{a}_{nm \frac{1}{2} m t} \langle 10 \text{Be} \alpha_1 I_1 M_1 T_1 M_{T_1} \rangle_{SD}, \quad (A4)$$

where $|10\text{Be} \alpha_1 I_1 M_1 T_1 M_{T_1}\rangle_{SD}$ is an NCSM state of the $(A-1)$ system $^{10}\text{Be}$ expanded in the HO Slater Determinant (SD) basis, $\{I_1 \ell_1 \ell_2 \ell_3 \}$ is the standard Wigner 6j-symbol [36], and $\hat{a}$ denotes $\sqrt{2x+1}$. The $nl$ HO quantum numbers in the $nlj$ single-particle states are omitted from now on for simplicity. The relationship between the SD eigenstates entering Eq. (A4) and the relative coordinate eigenstates in Eqs. (3) and (A3) is given by

$$|10\text{Be} \alpha_1 I_1 M_1 T_1 M_{T_1}\rangle_{SD} = |10\text{Be} \alpha_1 I_1 M_1 T_1 M_{T_1}\rangle \times \varphi_{00} \langle \tilde{R}_{c.m.}^{10}\rangle, \quad (A5)$$

with $\tilde{R}_{c.m.}^{10}$ the c.m. coordinate of $^{10}\text{Be}$ and $\varphi_{00}$ the HO wave function of the c.m. motion. Using Eq. (A4), the coupling term becomes:

$$\langle A \alpha_1 J_1 T_1 M_{T_1} \| \hat{O}_{\mu r}^{(\kappa \tau)} \| A \alpha_1 J_1 T_1 M_{T_1} \rangle_{SD} = \sum (-1)^{j_1 + j_2 + j_3} \left\langle I_1 \ell_1 \ell_2 \ell_3 \right| I_1 \ell_1 \ell_2 \ell_3 \rangle \times \langle I_1 M_1 j m | J_1 M_1 \rangle \langle T_1 M_{T_1} \frac{1}{2} m t | T_1 M_{T_1} \rangle \times \hat{a}_{nm \frac{1}{2} m t} \langle 10 \text{Be} \alpha_1 I_1 M_1 T_1 M_{T_1} \rangle_{SD}, \quad (A6)$$

where $\langle \hat{a}_{jm \frac{1}{2} m t} \rangle$ and $\langle \left[ a_{jm \frac{1}{2} m t} a_{jm \frac{1}{2} m t} \right] \rangle_{SD}$ are 1-particle and 2-particle-1-hole transition matrices between the composite and the target (here $^{11}\text{B}$ and $^{10}\text{Be}$) NCSM wave functions. Similarly as for the target eigenstates (A5), the composite system ($^{11}\text{Be}$ or $^{11}\text{B}$) eigenstates expanded in the HO SD basis are related to the relative coordinate eigenstates appearing in Eq. (A1) by

$$\langle A \alpha_1 J_1 T_1 M_{T_1} \| A \alpha_1 J_1 T_1 M_{T_1} \varphi_{00}(\tilde{q}_0) \rangle,$$

with $\tilde{q}_0$ the c.m. coordinate of the composite $A$-nucleon system and $\varphi_{00}$ the HO wave function of the c.m. motion. See also the appendix of Ref. [11] and Ref. [35]. The third term in Eq. (A1) is calculated by taking advantage of the following relation:

$$\langle A \alpha_1 J_1 T_1 M_{T_1} \| \hat{O}_{\mu r}^{(\kappa \tau)} \| A \alpha_1 J_1 T_1 M_{T_1} \rangle_{SD} = (-1)^{j_1 - j_3} \langle A \alpha_1 J_1 T_1 M_{T_1} \| \left[ \hat{O}_{\mu r}^{(\kappa \tau)} \right]^\dagger \hat{A}_\nu \| A \alpha_1 J_1 T_1 M_{T_1} \rangle_{SD}. \quad (A7)$$

Thus, Eq. (A6) is sufficient for both coupling terms in Eq. (A1).
The last term in Eq. (A1) is derived using a similar procedure:

\[
\begin{align*}
\text{SD} \left\langle \Phi_{\nu''}^{J_f T M_f} \right| \hat{A}_{\nu'} \hat{O}_{\nu''}^{(\kappa \tau)} \hat{A}_{\nu} \left| \Phi_{\nu}^{J_T T M_T} \right\rangle_{\text{SD}} &= \delta_{\alpha_1 \alpha_1'} \delta_{I_1 I_1'} \delta_{T_1 T_1'} \delta_{M_T M_T} \hat{J}_f \hat{J}_f \hat{s}' s \\
\times \sum_{j j'} (-1)^{I_1 + \kappa + J_1 + j} \left\{ I_1 \quad j \quad I_1' \quad j' \right\} \left\{ I_1' \quad \frac{1}{2} \quad s' \quad \ell' \quad J_f \quad j' \right\} \\
\times \hat{J}_f \hat{J}_f \hat{s}' s' \left\langle j \frac{1}{2} M_t \big| T_1 T_M \big| j \frac{1}{2} M_t \big| T_1 T_M \big| \rightangle \\
- \sum_{j j'} \hat{s}' \hat{s}' \hat{j}_f \hat{j}_f \hat{j}_4 \hat{j}_4 (-1)^{j' + j + \kappa + J_3 + j + I_1 - J_1} \left\{ I_1 \quad \ell \quad j \quad I_1' \quad \ell' \quad J_f \quad j' \right\} \\
\times \left\langle j \frac{1}{2} M_t \right| \hat{O}_{\nu''}^{(\kappa \tau)} \left| j \frac{1}{2} M_t \right\rangle_{\text{SD}} \left\langle T_1 T_M \big| \frac{1}{2} M_t \big| T_1 T_M \big| \rightangle \\
- \sum_{j j'} \hat{J}_f \hat{J}_f \hat{s}' \hat{s}' \left\langle j \frac{1}{2} M_t \big| T_1 T_M \big| j \frac{1}{2} M_t \big| T_1 T_M \big| \rightangle \\
\times \hat{J}_f \hat{J}_f \hat{s}' \hat{s}' \left\langle j \frac{1}{2} M_t \big| j \frac{1}{2} M_t \big| \right\rangle_{\text{SD}} \left\langle A - 1 \alpha_1' I_1' T_1' M_1' \bigg| \bigg( \hat{a}_j \frac{1}{2} M_t \hat{a}_j \frac{1}{2} M_t \bigg) \left( j \frac{1}{2} M_t \right) \bigg\rangle \left\langle A - 1 \alpha_1 I_1 T_1 M_1 \bigg| \bigg( \hat{a}_j \frac{1}{2} M_t \hat{a}_j \frac{1}{2} M_t \bigg) \left( j \frac{1}{2} M_t \right) \bigg\rangle_{\text{SD}} \\
\times \left\langle T_1 T_M \big| \frac{1}{2} M_t \big| T_1 T_M \big| \frac{1}{2} M_t \big| T_1 T_M \big| \rightangle \\
+ \delta_{\alpha_1 \alpha_1'} \delta_{\ell \ell'} \hat{s}' \hat{s}' \hat{j}_f \hat{j}_f (-1)^{j' + j + \kappa + l} \left\{ I_1 \quad \frac{1}{2} \quad s' \quad \ell' \quad J_f \quad j' \right\} \\
\times \hat{J}_f \hat{J}_f \hat{s}' \hat{s}' \left\langle j \frac{1}{2} M_t \big| j \frac{1}{2} M_t \big| \right\rangle_{\text{SD}} \left\langle A - 1 \alpha_1' I_1' T_1' M_1' \bigg| \bigg( \hat{a}_j \frac{1}{2} M_t \hat{a}_j \frac{1}{2} M_t \bigg) \left( j \frac{1}{2} M_t \right) \bigg\rangle \left\langle A - 1 \alpha_1 I_1 T_1 M_1 \bigg| \bigg( \hat{a}_j \frac{1}{2} M_t \hat{a}_j \frac{1}{2} M_t \bigg) \left( j \frac{1}{2} M_t \right) \bigg\rangle_{\text{SD}} \\
\times \left\langle T_1 T_M \big| \frac{1}{2} M_t \big| T_1 T_M \big| \frac{1}{2} M_t \big| T_1 T_M \big| \rightangle \\
\times \left\langle T_1 T_M \big| \frac{1}{2} M_t \big| T_1 T_M \big| \frac{1}{2} M_t \big| T_1 T_M \big| \rightangle \\
\right.
\end{align*}
\]

where \( \left\langle A - 1 \alpha_1' I_1' T_1' M_1' \right| \bigg( \hat{a}_j \frac{1}{2} M_t \hat{a}_j \frac{1}{2} M_t \bigg) \left( j \frac{1}{2} M_t \right) \bigg\rangle \)
and \( \left\langle A - 1 \alpha_1 I_1 T_1 M_1 \right| \bigg( \hat{a}_j \frac{1}{2} M_t \hat{a}_j \frac{1}{2} M_t \bigg) \left( j \frac{1}{2} M_t \right) \bigg\rangle \)
are two- and one-body density matrices between the target (here \(^{10}\text{Be}\)) NCSM wave functions. The 12j symbol is the 12j(II) definition in Ref. [37].

The reduced matrix elements in Eqs. (A6), (A7), (A8) are in the SD basis, thus they are not translationally invariant since they contain the spurious motion of the \((A-1)\)-nucleon cluster center of mass. Before transforming from the SD-space to coordinate space, these matrix elements must be made translationally invariant. The procedure to remove this spurious motion in Ref. [34] is generalized here to be applicable to operators of non-zero order. The SD cluster wavefunction is related to the invariant cluster wavefunction in the following way:

\[
\Phi_{\nu n}^{J T} = \sum_{n_e \ell \ell' N L J_r} \hat{\ell}' \hat{J}_r \left( -1 \right)^{s + \ell + L + J} \bigg\langle s \quad \ell' \quad J_r \quad \ell' \quad \ell \bigg\rangle_{\text{SD}} \left\langle n_e \ell \ell' N L (00n\ell) \right| \phi_{\nu n}^{J T} \left( \hat{\ell} \hat{J}_r \right) \vert_{\text{SD}} \left( 0 \right)
\]

where \( \phi_{\nu n}^{J T} \left( \hat{\ell} \hat{J}_r \right) \) is a generalized HO bracket for two particles with mass ratio \( d = \frac{a}{A-a} \) [38]. In the present case of a single-nucleon projectile \( a=1 \). Using Eq. (A9), the translationally-invariant reduced matrix element can be
extracted by inverting the following expression:

\[
\text{SD} \left\langle \Phi^{J^T,M_T}_{\nu',\nu} \left| \hat{A}_\nu \hat{O}^{(\nu')}_{\nu'} \hat{A}_\nu \right| \Phi^{J^T,M_T}_{\nu'} \right\rangle_{\text{SD}} = \sum_{NLLn_\ell,J_\ell,n'_\ell,J'_\ell} (-1)^{s+\ell+\ell} + J' - J + \kappa + L J_\ell \ell' J_\ell' \left\{ \frac{\kappa}{L} J_\ell J'_\ell \right\} \\
\times \left\{ s \ell J \ell' \right\} \left\{ s' \ell' J' \ell' \right\} \langle n_\ell \ell NLl' | 00n\ell' \rangle \frac{\pi_n}{\pi_\nu} \langle n'_\ell \ell NL\ell' | 00n'\ell' \rangle \frac{\pi_{n'}}{\pi_{\nu'}} \\
\times \left\langle \Phi^{J^T,M_T}_{\nu',n_\ell'_\ell} \left| \hat{A}_\nu \hat{O}^{(\nu')}_{\nu'} \hat{A}_\nu \right| \Phi^{J^T,M_T}_{\nu',n_\ell} \right\rangle. \\
\text{(A10)}
\]

Equation (A10) is a generalization of Eq. (32) in Ref. [34].

The removal of the spurious c.m. motion from the coupling matrix elements is still more straightforward. Following Refs. [11] and [30], we find

\[
\text{SD} \left\langle A\lambda J_T M_T \left| \hat{O}^{(\nu')}_{\nu'} \hat{A}_\nu \right| \Phi^{J^T,M_T}_{\nu'} \right\rangle = \langle n00l|00n\ell \rangle \frac{\pi_n}{\pi_{\nu}} \left\langle A\lambda J_T M_T \left| \hat{O}^{(\nu')}_{\nu'} \hat{A}_\nu \right| \Phi^{J^T,M_T}_{\nu'} \right\rangle \\
\text{with a generalized HO bracket due to the c.m. motion, which value is simply given by}
\]

\[
\langle n00l|00n\ell \rangle \frac{\pi_n}{\pi_{\nu}} = (-1)^{\ell} \left( \frac{A-a}{A} \right)^{2n+\ell}. \\
\text{(A11)}
\]

After removing the spurious c.m. motion using either Eq. (A10) or (A11), the removal of the matrix elements to coordinate space using Eq. (A2) is straight-forward with the exception of the first term in Eq. (A8). The first term in Eq. (A8) is completely carried over, thus it contains the Kronecker delta \(\delta_{nn'}\). The Kronecker delta would analytically convert to a Dirac-delta \(\delta(r - r')\) using Eq. (A2) assuming an infinitely large basis size. Of course, in practice the HO basis is finite, so Eq. (A2) will not properly transform the Kronecker delta from the first term in Eq. (A8). To account for this, we first split the operator between the target and projectile:

\[
\hat{O}_A = \hat{O}_{(A-1)} + \hat{O}_1.
\]

By splitting the operator, we can insert complete sets over the target and projectile NCSM states (note that in the rest of this section we omit isospin quantum numbers for simplicity):

\[
\left\langle \Phi^{J^T}_{\nu',n_\ell} \left| \hat{A}_\nu \hat{O}^{(\nu')} \hat{A}_\nu \right| \Phi^{J^T}_{\nu,n_\ell} \right\rangle = \sum_1 \left\langle \Phi^{J^T}_{\nu',n_\ell} \left| \hat{A}_\nu \hat{A}_\nu \right| A-1 \alpha_1 I_1 \right\rangle \\
\times \left\langle A-1 \alpha_1 I_1 \left| \hat{O}^{(\nu')} A \right| \Phi^{J^T}_{\nu,n_\ell} \right\rangle + \sum_2 \left\langle \Phi^{J^T}_{\nu',n_\ell} \left| \hat{A}_\nu \hat{A}_\nu \right| \alpha_2 I_2 \right\rangle \left\langle \alpha_2 I_2 \left| \hat{O}^{(\nu')} A \right| \Phi^{J^T}_{\nu,n_\ell} \right\rangle.
\]

After substituting Eq. (A4) and performing some angular momentum recoupling, the expression becomes:

\[
\left\langle \Phi^{J^T}_{\nu',n_\ell} \left| \hat{A}_\nu \hat{O}^{(\nu')} \hat{A}_\nu \right| \Phi^{J^T}_{\nu,n_\ell} \right\rangle = J_T J' \sum_1 \delta_1 \left\{ \kappa I_2 \right\} \left\{ \kappa I_1' \right\} \left\{ \delta_1 s' s \right\} \left\{ \delta_1 s s' \right\} (-1)^{J_T+\ell+\ell'} - s - I_2 - I_1' \\\n\times \left\langle \Phi^{J^T}_{\nu',n_\ell} \left| \hat{A}_\nu \hat{A}_\nu \hat{A}_\nu \right| \Phi^{J^T}_{\nu,n_\ell} \right\rangle + \left\langle A-1 \alpha_1 I_1 \left| \hat{O}^{(\nu')} A \right| \Phi^{J^T}_{\nu,n_\ell} \right\rangle \\
\times \left\langle A-1 \alpha_1 I_1 \left| \hat{O}^{(\nu')} A \right| \Phi^{J^T}_{\nu,n_\ell} \right\rangle + \left\langle A-1 \alpha_1 I_1 \left| \hat{O}^{(\nu')} A \right| \Phi^{J^T}_{\nu,n_\ell} \right\rangle \\
\times \left\langle \Phi^{J^T}_{\nu',n_\ell} \left| \hat{A}_\nu \hat{A}_\nu \hat{A}_\nu \right| \Phi^{J^T}_{\nu,n_\ell} \right\rangle, \\\n\text{(A12)}
\]

with the projectile states \(\alpha_2 I_2 T_2 M_T_2\) representing either a proton or a neutron with \(\alpha_2 = \pm 1\), \(I_2 = 1/2\). The cumulative quantum numbers \(\nu'\) and \(\tilde{\nu}'\) represent \(A-1\alpha_1' I_1' \alpha_2 I_2' s'\ell'\) and \(A-1\alpha_1 I_1 \alpha_2' I_2' s'\ell\), respectively. The matrix elements of \(\hat{A}_\nu \hat{A}_\nu\) are defined as the norm kernels in Ref. [13]:

\[
N_{\nu',\nu}^{J^T}(r, r') = \left\langle \Phi^{J^T}_{\nu',n_\ell} \left| \hat{A}_\nu \hat{A}_\nu \right| \Phi^{J^T}_{\nu,n_\ell} \right\rangle = \delta_{\nu',\nu} \frac{\delta(r' - r)}{r'} + \sum_2 R_{\nu',\nu}^{J^T}(r') \left[ N_{\nu',\nu}^{J^T} - \delta_{\nu',\nu} \right] R_{\nu,\nu}(r), \\\n\text{(A13)}
\]
where $N_{
u n'\nu n}^{J_f J_i} = \langle \Phi^{J_f}_{\nu n'} | \hat{A}_{\nu'} | \Phi^{J_i}_{\nu n} \rangle$ is the norm kernel in HO space. The coordinate-space norm kernel defined in Eq. (A13) is written to explicitly treat the $\delta$-term in coordinate space and subtracting the completely contracted part from the HO-space norm kernel. Using this expression, Eq. (A12) becomes:

$$
\langle \Phi^{J_f}_{\nu n'} | \hat{A}_{\nu'} \hat{O}(^{(\kappa)}_{\nu n'}) | \Phi^{J_i}_{\nu n} \rangle = J_f J_i \sum s s' \begin{pmatrix} \kappa & I_2 & I_1 \\ s & s' & \ell \end{pmatrix} \begin{pmatrix} \kappa & s' & s \\ \ell & J_1 & J_f \end{pmatrix} (-1)^{J_f+\ell-s-s-2-I_2-I_1}
\times \delta_{\nu'\nu} \frac{\delta(r' - r)}{r^{1/2}} \langle A-1 \alpha_1 I_1 | \hat{O}(^{(\kappa)}_{A-1}) | A-1 \alpha_1 I_1 \rangle
+ J_f J_i \sum s s' \begin{pmatrix} \kappa & I_2 & I_1 \\ s & s' & \ell \end{pmatrix} \begin{pmatrix} \kappa & s' & s \\ \ell & J_1 & J_f \end{pmatrix} (-1)^{J_f+\ell-I_2-I_1}
\times \delta_{\nu'\nu} \frac{\delta(r' - r)}{r^{1/2}} \langle \alpha_2 I_2 | \hat{O}(^{(\kappa)}_{\nu}) | \alpha_2 I_2 \rangle
+ \sum_{nn'} R_{n' n}(r') \langle \Phi^{J_f}_{\nu n'} | \hat{A}_{\nu'} | \hat{O}(^{(\kappa)}_{\nu n'}) - 1 | \hat{A}_{\nu} | \Phi^{J_i}_{\nu n} \rangle R_{n' \ell}(r').
$$

(A14)

The HO matrix element in the last line of Eq. (A14),

$$
\langle \Phi^{J_f}_{\nu n'} | \hat{A}_{\nu'} (\hat{O}(^{(\kappa)}_{\nu n'}) - 1) | \Phi^{J_i}_{\nu n} \rangle,
$$

corresponds to Eq. (A8) (after removing the c.m. motion) with the completely-contracted term omitted.
