Abstract: An inverse problem in practical scientific investigations is the process of computing unknown parameters from a set of observations where the observations are only recorded indirectly, such as monitoring and controlling quality in industrial process control. Linear regression can be thought of as linear inverse problems. In other words, the procedure of unknown estimation parameters can be expressed as an inverse problem. However, maximum likelihood provides an unstable solution, and the problem becomes more complicated if unknown parameters are estimated from different samples. Hence, researchers search for better estimates. We study two joint censoring schemes for lifetime products in industrial process monitoring. In practice, this type of data can be collected in fields such as the medical industry and industrial engineering. In this study, statistical inference for the Chen lifetime products is considered and analyzed to estimate underlying parameters. Maximum likelihood and Bayes’ rule are both studied for model parameters. The asymptotic distribution of maximum likelihood estimators and the empirical distributions obtained with Markov chain Monte Carlo algorithms are utilized to build the interval estimators. Theoretical results using tables and figures are adopted through simulation studies and verified in an analysis of the lifetime data. We briefly describe the performance of developed methods.

Keywords: Chen distributions; progressive type-II censoring; maximum likelihood; mean posterior; Bayesian estimation; MCMC

1 Introduction

Several types of monitoring data are available. One is the censoring scheme, which is a popular problem in life testing experiments. The oldest censoring projects are the so-called “type-I”, and the other is “type-II”. In practice, there are usually two random variables, i.e., time and the number of failures of items. This strategy of censoring projects shows how the examiner imagines the experiment based on a predetermined time. A random number of units is accounted for the first type-I of a censoring scheme, which means it may be assumed the exact time of stopping experiment. While the predetermined number of failure units and a random time in the type-II censoring scheme. In these two types of censoring schemes, companies cannot be removed

from an experiment until the final stage or the number of units fail. This process allows the
detection of some units that are defective after running the experiment. The mixture of these
types of censoring schemes is the so-called hybrid censoring system [1]. To remove elements from
the test at any stage of the trial is known as a progressive censoring scheme [2]. The topic of
progressive censoring has developed in different scientific fields, and has attracted much attention
in recent years. Several authors have studied this type of data [3,4]. There are different types
of progressive censoring schemes. The idea of the progressive type-I censoring scheme is to test
line \( \eta \) and determine the number \( m \) of failure units, and suppose \( n \) independent elements are
tested under the censoring scheme \( r = \{ r_1, r_2, \ldots, r_m \} \). The failure unit is removed at \( \min(\tau, T_m) \),
where \( T_m \) is the stopping time of the number of failure units \( m \). After each failure time \((T_i, r_i)\),
survival units are removed from the trial, where \( i = 1, 2, \ldots, J \) and \( J \leq m \). In a progressive type-
II censoring project, the number \( m \) of failure units and \( r = \{ r_1, r_2, \ldots, r_m \} \) are determined, and
we suppose \( n \) independent units are examined and the experiment is stopped at \( T_m \). After each failure
line \( \eta \) or \( \eta_2 \) under the same conditions. Assume two independent samples \( S_1 \) and \( S_2 \) are chosen from these
lines for experimental testing. The experiment runs under some consideration of time and cost,
and the experimenter reports that it terminates after a predetermined time or number of failures.
This is called a joint censoring scheme [11]. The procedure of joint progressive type-II censoring
was described previously, where the sample size \( S_1 + S_2 \) is taken as \( S_1 \) from line \( \eta_1 \) and \( S_2 \) from
line \( \eta_2 \). The integers \( m \) and \( r = \{ r_1, r_2, \ldots, r_m \} \) are determined to satisfy the form \( S_1 + S_2 + \sum_{i=1}^m r_i \).
The element \( r_1 \) is removed immediately from the experiment. We observe the first failure unit,
say \( T_1 \) and has line \( W_1 \) from line \( \eta_1 \) or \( \eta_2 \), say \((t_1, \omega_1)\). Also, the number \( r_2 \) is removed from the test after we examine the second failure unit, say \( T_2 \) and has line \( W_2 \), say \((t_2, \omega_2)\). The experiment continues until \((t_m, \omega_m)\) is observed, where \( w_i \) takes the value 1 or 0, depending on
lines \( \eta_1 \) or \( \eta_2 \). The result of the previous examination \( t = \{(t_1, \omega_1), (t_2, \omega_2), \ldots, (t_m, \omega_m)\} \) is called
the joint progressive type-II censoring procedure. The concept of a balanced joint progressive
type-II censoring scheme was considered by [12] for analytically more straightforward estimators
than the other type of progressive censoring procedure. Several authors have discussed statistical
inference using different distributions, such as two exponential distributions [12]. The procedure of
time using Weibull distributions was investigated [13]. The interpretation of the balanced joint
progressive type-II censoring scheme starts with samples of size \( S_1 + S_2 \), taken from \( \eta_1 \) and \( \eta_2 \), respectively. Integers \( m \) and the integers \( r = \{ r_1, r_2, \ldots, r_m \} \) are determined to
satisfy \( m + \sum_{i=1}^{m-1} r_i < \min(S_1, S_2) \). The failure times and types are observed, say \((t_i, \omega_i), i = 1, 2, \ldots, m\). Fig. 1 shows the main idea of a joint progressive type-II censoring scheme. This study
discusses the properties of Chen lifetime estimation procedures under a joint progressive type-II
censoring scheme. The Chen lifetime distribution with two parameters was introduced by [14].
This study’s objective is to build a balanced joint progressive type-II censoring procedure for
the Chen lifetime distribution and parameter estimation with the maximum likelihood estimator
(MLE) and Bayes methods. The developed methods are also used to measure the same Chen
lifetime products’ relative merits under the same conditions. Estimators are evaluated through
numerical data analysis and assessed through a simulation study. The remainder of this article
is organized as follows. The main principle and model formulation are given in Section 2. Point
MLE and interval estimators are introduced in Section 3. Section 4 discusses Bayes point and
credible intervals. Estimators under numerical examples and simulation studies are discussed
in Section 5. We summarize some comments which are extracted from numerical methods in Section 6.

### 2 Model Formulation

Assume two production lines, and a random sample of size $S_1 + S_2$, where $S_1$ comes from line $\eta_1$ and $S_2$ from line $\eta_2$. The integers $m$ and $r = \{r_1, r_2, \ldots, r_m\}$ are determined to satisfy $m + \sum_{i=1}^{m-1} r_i < \min(S_1, S_2)$. Suppose $t_1$ is observed from some units that are taken from line $\eta_1$, then, $r_1$ survival component is removed from $S_1$ and $r_1 + 1$ survival component is removed from $S_2$ when the second failure $t_2$ is observed if $t_2$ is chosen from the line $\eta_2$. In that case, $r_2 + 1$ survival component is removed from $S_1 - r_1 - 1$, and $r_2$ survival component is removed from the sample $S_2 - r_2 - 1$. The test continues in this manner until the $m$th failure $t_m$ is observed. If the final failure is from line $\eta_1$, then the survival components $S_1 - m - \sum_{i=1}^{m-1} r_i$ are removed from $\eta_1$, and $S_2 - (m - 1) - \sum_{i=1}^{m-1} r_i$ are removed from $\eta_2$. If the final failure belongs to line $\eta_2$, then the survival units $S_1 - (m - 1) - \sum_{i=1}^{m-1} r_i$ are removed from $\eta_1$, and $S_2 - m - \sum_{i=1}^{m-1} r_i$ are removed from $\eta_2$. Fig. 1 shows the scheme of joint balanced progressive type-II censoring. The observed data $t = \{(t_1, \omega_1), (t_2, \omega_2), \ldots, (t_m, \omega_m)\}$ are called balanced joint progressive type-II censoring samples. Under consideration that $S_1$ comes from the line $\eta_1$, and it has independent and identically distribution of lifetimes $\{X_1, X_2, \ldots, X_{S_1}\}$ and $S_2$ comes from the line $\eta_2$, and it has independent and identically distribution of lifetimes $\{X^*_1, X^*_2, \ldots, X^*_{S_2}\}$. These samples distributed with populations have probability density (PDFs) and cumulative distribution (CDFs) functions are given, respectively, by the functions $f_j(.)$ and $F_j(.)$, $j = 1, 2$. Then the balanced joint progressive type-II sample $t = \{t_1, t_2, \ldots, t_m\}$ is taken from $\{X_1, X_2, \ldots, X_{S_1}, X^*_1, X^*_2, \ldots, X^*_{S_2}\}$, where $m = m_1 + m_2$, $m_1$ is the number of failed units from line $\eta_1$, and $m_2$ is the number of failed units from line $\eta_2$. The observed balanced joint progressive type-II censoring sample is $t = \{(t_1, \omega_1), (t_2, \omega_2), \ldots, (t_m, \omega_m)\}$, where $\omega_i$ takes the value 1 or 0, depends on line $\eta_1$ or $\eta_2$, $m_1 = \sum_{i=1}^{m_2} \omega_i$ and $m_2 = \sum_{i=1}^{m_2} (1 - \omega_i)$.

The joint likelihood rule under two progressive type-II censoring samples $t = \{(t_1, \omega_1), (t_2, \omega_2), \ldots, (t_m, \omega_m)\}$ is

$$L(t) \propto (R_1(t_1))^{T_1} (R_2(t_m))^{T_2} (h_1(t_m))^{m_1} (h_2(t_m))^{1-m_1}$$

$$\times \prod_{i=1}^{m-1} (h_1(t_i))^{\omega_i} (h_2(t_i))^{1-\omega_i} (R_1(t_i) R_2(t_i))^{r_i+1},$$  \hspace{1cm} (1)
where
\[ I_j = S_j - (m - 1) - \sum_{i=1}^{m-1} r_i, j = 1, 2, \]  
(2)

and \( R_j(.) \) and \( h_j(.) \) are reliability and hazard rate functions, respectively. Under the described model, the probability density functions (PDFs) and cumulative distribution functions (CDFs) of the tested unit and chosen from two lines \( \eta_1 \) and \( \eta_2 \) have Chen lifetime distributions with PDFs given by
\[ f_j(t) = \alpha_j \lambda_j t^{\alpha_j-1} \exp\{t^{\alpha_j}\} \exp\{\lambda_j (1 - \exp\{t^{\alpha_j}\})\}, \quad t > 0, \quad (\alpha_j \lambda_j) > 0. \]  
(3)

Reliability and hazard rate functions, respectively, are given by
\[ F_j(t) = 1 - \exp\{\lambda_j (1 - \exp\{t^{\alpha_j}\})\}, \]  
(4)
\[ S_j(t) = \exp\{\lambda_j (1 - \exp\{t^{\alpha_j}\})\}, \]  
(5)

and
\[ h_j(t) = \alpha_j \lambda_j t^{\alpha_j-1} \exp\{t^{\alpha_j}\}, \]  
(6)

where \( \alpha_j \) and \( \lambda_j \) are the respective shape and scale parameters of the Chen distribution. Hence, a bathtub-shaped failure rate is noticed when \( \alpha_j \geq 1 \), and an exponential form can be obtained when \( \alpha_j = 1 \) [15]. Fig. 2d plots the properties of the Chen distribution. It is clearly seen that \( h(t) \) provides a bathtub-shaped curve when \( \alpha = 1 \).

Figure 2: Examples of the scaled Chen distribution for different values of \( \alpha \) with \( \lambda = 1 \): (a) Chen distribution; (b) Cumulative distribution; (c) Reliability function; and (d) Hazard rate function.
3 Maximum Likelihood Estimation

The joint likelihood function in Eq. (1) without a normalized constant under a Chen lifetime distribution is defined as

\[ L(\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t) \]

\[ \propto (\alpha_1, \lambda_1)^{m_1} (\alpha_2, \lambda_2)^{m_2} \exp \left\{ (\alpha_1 - 1) \sum_{i=1}^{m} \omega_i \log t_i + \sum_{i=1}^{m} \omega_i t_i^{\alpha_1} + \lambda_1 \sum_{i=1}^{m-1} (r_i + 1) \left( 1 - \exp \left\{ t_i^{\alpha_1} \right\} \right) + \lambda_1 I_1 \left( 1 - \exp \left\{ t_i^{\alpha_1} \right\} \right) + (\alpha_2 - 1) \sum_{i=1}^{m-1} (1 - \omega_i) \log t_i + \sum_{i=1}^{m-1} (1 - \omega_i) t_i^{\alpha_2} + \lambda_2 \sum_{i=1}^{m-1} (r_i + 1) \left( 1 - \exp \left\{ t_i^{\alpha_2} \right\} \right) + \lambda_2 I_2 \left( 1 - \exp \left\{ t_i^{\alpha_2} \right\} \right) \right\}. \] (7)

After taking the logarithms of both sides, the joint likelihood function in Eq. (7) becomes

\[ \ell(\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t) \]

\[ \propto m_1 (\alpha_1, \lambda_1) + m_2 (\alpha_2, \lambda_2) + (\alpha_1 - 1) \sum_{i=1}^{m} \omega_i \log t_i + \sum_{i=1}^{m} \omega_i t_i^{\alpha_1} + \lambda_1 \sum_{i=1}^{m-1} (r_i + 1) \left( 1 - \exp \left\{ t_i^{\alpha_1} \right\} \right) + \lambda_1 I_1 \left( 1 - \exp \left\{ t_i^{\alpha_1} \right\} \right) + (\alpha_2 - 1) \sum_{i=1}^{m-1} (1 - \omega_i) \log t_i + \sum_{i=1}^{m-1} (1 - \omega_i) t_i^{\alpha_2} + \lambda_2 \sum_{i=1}^{m-1} (r_i + 1) \left( 1 - \exp \left\{ t_i^{\alpha_2} \right\} \right) + \lambda_2 I_2 \left( 1 - \exp \left\{ t_i^{\alpha_2} \right\} \right), \] (8)

which is used to represent the point and interval estimators of underlying parameters.

3.1 MLEs

The likelihood rule is obtained from Eq. (8) by taking partial derivatives with respect to the parameter vectors \((\alpha_1, \alpha_2, \lambda_1, \lambda_2)\) and equating to zero.

The equation \[ \frac{\partial \ell(\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t)}{\partial \lambda_1} = 0 \] is reduced to

\[ \lambda_1 = \frac{m_1}{\sum_{i=1}^{m-1} (r_i + 1) \left( \exp \left\{ t_i^{\alpha_1} \right\} - 1 \right)} + I_1 \left( \exp \left\{ t_m^{\alpha_1} \right\} - 1 \right). \] (9)

The equation \[ \frac{\partial \ell(\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t)}{\partial \lambda_2} = 0 \] is reduced to

\[ \lambda_2 = \frac{m_2}{\sum_{i=1}^{m-1} (r_i + 1) \left( \exp \left\{ t_i^{\alpha_2} \right\} - 1 \right)} + I_2 \left( \exp \left\{ t_m^{\alpha_2} \right\} - 1 \right). \] (10)
The equation \[ \frac{\partial \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t)}{\partial \alpha_1} = 0 \] is reduced to

\[ \frac{m_1}{\alpha_1} + \sum_{i=1}^{m} \omega_i (1 + t_i^{a_1}) \log t_i - \lambda_1 \sum_{i=1}^{m-1} (r_i + 1) t_i^{\alpha_1} \log t_i \exp \{ t_i^{\alpha_1} \} - \lambda_1 I_1 t_m^{\alpha_1} \log t_m \exp \{ t_m^{\alpha_1} \} = 0. \] (11)

The equation \[ \frac{\partial \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t)}{\partial \alpha_2} = 0 \] is reduced to

\[ \frac{m_2}{\alpha_2} + \sum_{i=1}^{m} (1 - \omega_i) (1 + t_i^{a_2}) \log t_i - \lambda_2 \sum_{i=1}^{m-1} (r_i + 1) t_i^{\alpha_2} \log t_i \exp \{ t_i^{\alpha_2} \} - \lambda_2 I_2 t_m^{\alpha_2} \log t_m \exp \{ t_m^{\alpha_2} \} = 0. \] (12)

After replacing \( \lambda_1 \) in (9)–(11) and \( \lambda_2 \) in (10)–(12), we obtain

\[ \frac{m_1}{\alpha_1} + \sum_{i=1}^{m} \omega_i (1 + t_i^{a_1}) \log t_i - \frac{m_1}{\alpha_1} \sum_{i=1}^{m-1} (r_i + 1) t_i^{a_1} \log t_i \exp \{ t_i^{a_1} \} - I_1 t_m^{a_1} \log t_m \exp \{ t_m^{a_1} \} = 0, \] (13)

and

\[ \frac{m_2}{\alpha_2} + \sum_{i=1}^{m} (1 - \omega_i) (1 + t_i^{a_2}) \log t_i - \frac{m_2}{\alpha_2} \sum_{i=1}^{m-1} (r_i + 1) t_i^{a_2} \log t_i \exp \{ t_i^{a_2} \} - I_2 t_m^{a_2} \log t_m \exp \{ t_m^{a_2} \} = 0. \] (14)

Nonlinear Eqs. (13) and (14) with only one parameter can be solved using any iteration method such as Newton-Raphson or fixed point iteration. The parameter estimates \( \hat{\alpha}_1 \) and \( \hat{\alpha}_2 \) are obtained, and parameter estimates \( \hat{\lambda}_1 \) and \( \hat{\lambda}_2 \) are obtained from Eqs. (9) and (10) after replacing \( \alpha_1 \) and \( \alpha_2 \) by \( \hat{\alpha}_1 \) and \( \hat{\alpha}_2 \). If \( m_1 = 0 \) or \( m_2 = 0 \), then the parameter values \( \alpha_1 \) and \( \lambda_1 \) or \( \alpha_2 \) and \( \lambda_2 \) cannot be obtained [16].

3.2 Asymptotic Confidence Interval

To obtain interval estimates of unknown parameters requires the computation of the Fisher information matrix, which is defined by the negative expectation of the partial second derivative of the log-likelihood rule using (8),

\[ \sum = -E \left( \frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t)}{\partial \theta_i \partial \theta_j} \right) , \] (15)

where \( \theta = (\alpha_1, \alpha_2, \lambda_1, \lambda_2) \). In practice, the Fisher information matrix with a large sample can be approximated using the approximate information matrix,

\[ \sum_0 = - \left( \frac{\partial^2 \ell (\hat{\alpha}_1, \hat{\alpha}_2, \hat{\lambda}_1, \hat{\lambda}_2 | t)}{\partial \theta_i \partial \theta_j} \right) \bigg|_{\hat{\theta}=(\hat{\alpha}_1, \hat{\lambda}_1, \hat{\alpha}_2, \hat{\lambda}_2)} . \] (16)

Therefore, under the rule of asymptotic normality distribution of computing \( \hat{\theta} = (\hat{\alpha}_1, \hat{\alpha}_2, \hat{\lambda}_1, \hat{\lambda}_2) \) with mean \( (\alpha_1, \alpha_2, \lambda_1, \lambda_2) \) and variance covariance matrix \( \sum_0 \). The approximate confidence intervals for model parameters are defined as

\[ \hat{\alpha}_1 \pm Z_{\gamma} \sqrt{\sum_{11}}, \]
\[ \hat{\alpha}_2 \pm Z_{\gamma} \sqrt{\sum_{22}}, \]
\[
\hat{\lambda}_1 \mp Z_{\gamma} \sqrt{\bar{e}_{33}},
\]
\[
\hat{\lambda}_2 \mp Z_{\gamma} \sqrt{\bar{e}_{44}},
\]
where the diagonal of the approximate variance-covariance matrix \(\sum_0\) represents the values \(e_{11}, e_{22}, e_{33},\) and \(e_{44}\), and \(Z_{\gamma}\) has a standard normal distribution with right-tail probability \(\gamma\). The other variances are obtained using the partial derivative of the log-likelihood rule in Eq. (8),

\[
\frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \lambda_j^2} = -\frac{m_j}{\lambda_j^2}, \quad j = 1, 2, \quad (18)
\]

\[
\frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \alpha_1^2} = -\frac{m_1}{\alpha_1^2} + \sum_{i=1}^{m} \omega_i t_i^{\alpha_1} \log^2 t_i - \lambda_1 \sum_{i=1}^{m-1} (r_i + 1) t_i^{\alpha_1} (1 + t_i^{\alpha_1}) \log^2 t_i \exp \{t_i^{\alpha_1}\}
- \lambda_1 I_1 \alpha_1 (1 + t_i^{\alpha_1}) \log^2 t_i \exp \{t_i^{\alpha_1}\}, \quad (19)
\]

\[
\frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \alpha_2^2} = -\frac{m_1}{\alpha_2^2} + \sum_{i=1}^{m} (1 - \omega_i) t_i^{\alpha_2} \log^2 t_i - \lambda_2 \sum_{i=1}^{m-1} (r_i + 1) t_i^{\alpha_2} (1 + t_i^{\alpha_2}) \log^2 t_i \exp \{t_i^{\alpha_2}\}
- \lambda_2 I_2 \alpha_2 (1 + t_i^{\alpha_2}) \log^2 t_i \exp \{t_i^{\alpha_2}\}, \quad (20)
\]

\[
\frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \alpha_1 \partial \lambda_1} = \frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \lambda_1 \partial \alpha_1} = -\sum_{i=1}^{m-1} (r_i + 1) t_i^{\alpha_1} \log t_i \exp \{t_i^{\alpha_1}\}
- I_1 \alpha_1 \log t_i \exp \{t_i^{\alpha_1}\}, \quad (21)
\]

\[
\frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \alpha_2 \partial \lambda_2} = \frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \lambda_2 \partial \alpha_2} = -\sum_{i=1}^{m-1} (r_i + 1) t_i^{\alpha_2} \log t_i \exp \{t_i^{\alpha_2}\}
- I_2 \alpha_2 \log t_i \exp \{t_i^{\alpha_2}\}, \quad (22)
\]
and

\[
\frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \alpha_1 \partial \lambda_2} = \frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \lambda_2 \partial \alpha_1} = \frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \alpha_2 \partial \lambda_1} = \frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \lambda_1 \partial \alpha_2}
= \frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \lambda_1 \partial \lambda_2} = \frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \lambda_2 \partial \lambda_1} = \frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \alpha_1 \partial \alpha_2}
= \frac{\partial^2 \ell (\alpha_1, \alpha_2, \lambda_1, \lambda_2|t)}{\partial \alpha_2 \partial \alpha_1}, \quad (23)
\]
4 Bayes with MCMC Methods

We need to use Bayes approaches with the MCMC method because of the dimensionality of the model. Bayes estimation requires prior information about the model parameters, which are considered in this study to be independent gamma priors. Then, the available prior information is modeled as

\[ \theta_i \xrightarrow{\text{distributed as}} \text{gamma} \left( a_i, b_i \right), \quad \left( a_i, b_i > 0 \right), \quad i = 1, 2, 3, 4, \]

where \( \theta = (\alpha_1, \alpha_2, \lambda_1, \lambda_2) \). The joint distribution of prior densities is formed by

\[ P^*(\theta_i) = \prod_{i=1}^{4} \frac{b_i^{a_i}}{\Gamma(a_i)} \theta_i^{a_i-1} \exp(-b_i \theta_i). \quad (25) \]

Following this, the information about the model parameters is obtained from the prior information and the data, which provides the posterior distribution as

\[ P(\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t) = \frac{P^*(\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t) L(\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t)}{\int \int \int \int_{\alpha_1\alpha_2\lambda_1\lambda_2} P^*(\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t) L(\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t) d\lambda_2 d\lambda_1 d\alpha_2 d\alpha_1}, \quad (26) \]

where the denominator of the fraction can be removed since it contains no information about \( \theta \). The proportional form from posterior distribution (26) with prior distribution (25) and likelihood rule (7) is defined as

\[ P(\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t) \propto \alpha_1^{m_1+a_1-1} \alpha_2^{m_2+a_2-1} \lambda_1^{m_1+a_3-1} \lambda_2^{m_2+a_4-1} \]

\[ \times \exp \left\{ -b_1 a_1 - b_3 \lambda_1 + (\alpha_1 - 1) \sum_{i=1}^{m} \omega_i \log t_i + \sum_{i=1}^{m} \omega_i t_i^{\rho_1} \right\} \]

\[ + \lambda_1 \sum_{i=1}^{m-1} (r_i + 1) \left( 1 - \exp \{ t_i^{\rho_1} \} \right) + \lambda_1 I_1 \left( 1 - \exp \{ t_i^{\rho_1} \} \right) \]

\[ - b_2 a_2 - b_4 \lambda_2 + (\alpha_2 - 1) \sum_{i=1}^{m} (1 - \omega_i) \log t_i + \sum_{i=1}^{m} (1 - \omega_i) t_i^{\rho_2} \]

\[ + \lambda_2 \sum_{i=1}^{m-1} (r_i + 1) \left( 1 - \exp \{ t_i^{\rho_2} \} \right) + \lambda_2 I_2 \left( 1 - \exp \{ t_i^{\rho_2} \} \right) \}. \quad (27) \]

The Bayes estimators are computed with respect to the loss rule; then the Bayes method of any function \( \pi(\alpha_1, \alpha_2, \lambda_1, \lambda_2) \) under the rule of the squared-error loss (SEL) function is presented by

\[ \hat{\pi}(\alpha_1, \alpha_2, \lambda_1, \lambda_2) = \mathbb{E}_P(\pi(\alpha_1, \alpha_2, \lambda_1, \lambda_2)) = \int_{\alpha_1} \int_{\alpha_2} \int_{\lambda_1} \int_{\lambda_2} P(\alpha_1, \alpha_2, \lambda_1, \lambda_2 | t) d\lambda_2 d\lambda_1 d\alpha_2 d\alpha_1. \quad (28) \]

The integrals in Eqs. (26) and (28) generally cannot be obtained in explicit form, but can be solved by approximation, such as numerical integration or Lindley approximation. One of the
most frequently applied methods is the MCMC method, which is used to compute point and interval estimates as follows. The full conditional distributions can be described as

\[
P_1(\alpha_1|\lambda_1) \propto \alpha_1^{m_1 + a_1 - 1} \exp \left\{-b_1 a_1 + \alpha_1 \sum_{i=1}^{m} \omega_i \log t_i + \sum_{i=1}^{m} \omega_i i_1^{\alpha_1} \right\}
- \lambda_1 \sum_{i=1}^{m-1} (r_i + 1) \exp \{i_1^{\alpha_1}\} - \lambda_1 I_1 \exp \{i_1^{\alpha_1}\},
\]

(29)

\[
P_2(\alpha_2|\lambda_2) \propto \alpha_2^{m_2 + a_2 - 1} \exp \left\{-b_2 a_2 + \alpha_2 \sum_{i=1}^{m} \omega_i \log t_i + \sum_{i=1}^{m} (1 - \omega_i) i_2^{\alpha_2} \right\}
- \lambda_2 \sum_{i=1}^{m-1} (r_i + 1) \exp \{i_2^{\alpha_2}\} - \lambda_2 I_2 \exp \{i_2^{\alpha_2}\},
\]

(30)

\[
P_3(\lambda_1|\alpha_1) \propto \lambda_1^{m_1 + a_1 - 1} \exp \left\{-b_3 \lambda_1 + \lambda_1 \sum_{i=1}^{m} (r_i + 1) \left(1 - \exp \{i_1^{\alpha_1}\}\right) \right\}
+ \lambda_1 I_1 \left(1 - \exp \{i_1^{\alpha_1}\}\right),
\]

(31)

and

\[
P_4(\lambda_2|\alpha_2) \propto \lambda_2^{m_2 + a_2 - 1} \exp \left\{-b_4 \lambda_2 + \lambda_2 \sum_{i=1}^{m} (r_i + 1) \left(1 - \exp \{i_2^{\alpha_2}\}\right) \right\}
+ \lambda_2 I_2 \left(1 - \exp \{i_2^{\alpha_2}\}\right).
\]

(32)

Then the full conditional distributions are reduced to gamma distributions represented by Eqs. (31) and (32), and two distributions similar to normal distributions, shown as Eqs. (29) and (30). The MCMC methods have the forms of Gibbs algorithms, and the more general Metropolis-Hastings (MH) under Gibbs algorithms [17]. The following algorithm describes MCMC methods.

Step 1: Start with an initial vector \( \hat{\theta} = (\hat{\alpha}_1, \hat{\alpha}_2, \hat{\lambda}_1, \hat{\lambda}_2) \) and indicator \( \rho = 1 \).

Step 2: The values \( \lambda_j^{(\rho)}, j = 1,2 \) are generated from conditional distributions presented by Eqs. (31) and (32), respectively.

Step 3: The values \( \alpha_j^{(\rho)}, j = 1,2 \) are generated from conditional distributions presented by Eqs. (29) and (30) with the MH algorithm using normal proposal distributions with mean \( \alpha_j^{(\rho-1)} \) and variance obtained from approximate information matrix, respectively.

Step 4: The vector \( \theta^{(\rho)} = (\alpha_1^{(\rho)}, \alpha_2^{(\rho)}, \lambda_1^{(\rho)}, \lambda_2^{(\rho)}) \) is recorded; hence, \( \rho = \rho + 1 \).

Step 5: Steps (2) to (4) are repeated \( S \) times.

|               |            | \(\alpha_2\) | 3.426 (0.95) | 3.425 (0.94) | 2.909 (0.92) |
|               |            | \(\lambda_1\) | 0.417 (0.94) | 0.421 (0.95) | 0.400 (0.94) |
|               |            | \(\lambda_2\) | 0.315 (0.93) | 0.318 (0.93) | 0.309 (0.93) |

with posterior variance of \( \Theta \),

\[
V(\theta | t) = \frac{1}{S - S^*} \sum_{i=S^*+1}^{S} (\theta^{(i)} - \hat{\theta}_{IB})^2.
\]
Step 7: The $100(1-2\gamma)$% credible intervals can be obtained from the empirical distribution of $\theta_i$ after putting the values in ascending order; hence, a credible interval is formed by

$$
\left(\hat{\theta}_{i\gamma(S-S^*)}, \hat{\theta}_{i(1-\gamma)(S-S^*)}\right),
$$

where $\theta = (\alpha_1, \alpha_2, \lambda_1, \lambda_2)$.

5 Numerical Computation

5.1 Simulation Studies

Two estimation methods, classical ML and Bayes estimation under Chen lifetime distribution, are discussed and developed in this study. We compare and assess these methods under the MCMC algorithms. We report the results with various sample sizes $(S_1, S_2)$, several sample sizes of failure units $m$, and censoring procedures $r$. We fix parameters at $(\alpha_1, \lambda_1) = (0.5, 0.5)$ and $(\alpha_1, \lambda_1) = (0.7, 0.4)$. The validity of numerical results is determined by the mean value (MV) and mean squared-error (MSE) for point estimators. The probability coverage (PC) and average interval length (AL) are used to measure interval estimators. The results are summarized in Tabs. 1 and 2 for two sets of prior information (non-informative prior 0 and informative prior 1). The simulation study used 1000 balanced progressive type-II samples. For Bayes results, the producer was considered under the rule of the squared-error loss function and 11000 iterations of MCMC, with the first 1000 iterations as burn-in. The results are reported in Tabs. 1 and 2.

5.2 Data Analysis

Let Chen distribution with parameter values $(\alpha_1, \lambda_1) = (1.5, 1.1)$ and $(\alpha_2, \lambda_2) = (1.8, 0.9)$ and the prior distributions with parameters $(a_1, b_1) = (4, 2)$, $(a_2, b_2) = (3, 2.0)$, $(a_3, b_3) = (2.0, 1.5)$ and $(a_4, b_4) = (2, 2.5)$ are used to apply Bayes approaches.

| Parameter | ML  | BMCMC | 95% ACIs | Length | 95% CIs | Length |
|-----------|-----|-------|----------|--------|---------|--------|
| $\alpha_1 = 1.5$ | 1.117 | 1.241 | (0.6725,1.5615) | 0.889 | (0.7206,1.5733) | 0.853 |
| $\lambda_1 = 1.1$ | 1.147 | 1.109 | (0.5478,1.6028) | 1.055 | (0.6101,1.6327) | 1.022 |
| $\alpha_2 = 1.8$ | 1.075 | 1.321 | (0.5176,1.9768) | 1.459 | (0.6186,1.8626) | 1.244 |
| $\lambda_2 = 0.9$ | 0.744 | 0.837 | (0.2432,1.2438) | 1.001 | (0.3389,1.3381) | 0.999 |

Under consideration two sample of size $(S_1, S_2) = (40, 40)$, censoring scheme $r = \{9, 0^{(28)}\}$, with the number of failures $m = 30$. Then the sample can be generated with sample size $S_1 = 30$.
from a Chen distribution with parameters $(1.5, 1.1)$ and with size $S_2$ from a Chen distribution with parameters $(1.8, 0.9)$ using the algorithms [18]. The two progressive type-II samples are used to generate balanced joint progressive type-II samples with respect to $r = \{9, 0^{(28)}\}$ and $m = 30$. The joint sample and its type are reported in Tab. 3. The results of point estimation and interval MLEs are reported in Tab. 4. We plot the monitoring of the MCMC and the corresponding histogram in Figs. 3–10, which show the quality of the empirical posterior distribution generated by MCMC methods.

6 Concluding Remarks

Products from different production lines were investigated using a joint censoring procedure under the same conditions. The balanced joint censoring procedure has been shown considerable attention over the last few years. In this study, we discussed products that follow a Chen lifetime distribution. We discussed the ML and Bayes estimates to estimate the underlying parameters of two Chen lifetime distributions. Numerical results were obtained to compare the theoretical performance results. Some points are observed from numerical results, which are summarized as follows.

From the results in Tabs. 1 and 2, show that the balanced joint progressive type-II censoring procedure provides better excellent results for products have Chen lifetime distribution.

Estimation results under the Bayes method and informative prior distribution provide better estimation than ML and non-informative prior methods according to the MSE.

For non-informative priors, there are no significant differences between MLEs and Bayes estimates.

The effective sample size $m$ can be increased by reducing the MSEs and interval lengths.
