**ABSTRACT**

Functions of prokaryotic Argonautes (pAgos) have long remained elusive. Recently, Argonautes of the bacteria *Rhodobacter sphaeroides* and *Thermus thermophilus* were demonstrated to be involved in host defense. The Argonaute of the archaeon *Pyrococcus furiosus* (PfAgo) belongs to a different branch in the phylogenetic tree, which is most closely related to that of RNA interference-mediating eukaryotic Argonautes. Here we describe a functional and mechanistic characterization of PfAgo. Like the bacterial counterparts, archaeal PfAgo contributes to host defense by interfering with the uptake of plasmid DNA. PfAgo utilizes small 5′-phosphorylated DNA guides to cleave both single stranded and double stranded DNA targets, and does not utilize RNA as guide or target. Thus, with respect to function and specificity, the archaeal PfAgo resembles bacterial Argonautes much more than eukaryotic Argonautes. These findings demonstrate that the role of Argonautes is conserved through the bacterial and archaeal domains of life and suggests that eukaryotic Argonautes are derived from DNA-guided DNA-interfering host defense systems.

**INTRODUCTION**

Eukaryotic Argonaute proteins (eAgos) are the key players in RNA interference (RNAi) pathways (reviewed in (1–3)). During RNAi, eAgos are loaded with small 5′-phosphorylated RNAs, ranging from 20 to 30 nt, in a pathway-specific ribonuclease-dependent process. The eAgos sometimes form the core of a multiprotein RNA-induced silencing complex (RISC; reviewed in (4)). Depending on which proteins associate with eAgos, Argonaute-mediated target binding can be specifically adjusted to differentially control gene expression. RNA interference generally results in silenced expression of the target gene, via functional variations that include decreased transcription (heterochromatin formation), decreased translation (mRNA binding) and decreased mRNA half-life (mRNA cleavage, mRNA de-adenylation).

Whereas prokaryotes also possess Argonaute proteins (pAgos), they appear to lack the accessory proteins involved in eukaryotic RNA interference pathways (3,5,6). Initially, pAgo variants from *Aquifex aeolicus* and *Thermus thermophilus* were characterized biochemically, revealing that they could use DNA guides for RNA and DNA target cleavage (7–9). Recently, it has become evident that at least some bacterial Agos play a role in host defense by interfering with invading nucleic acids (10–12). *Rhodobacter sphaeroides* Argonaute (*RsAgo*) acquires small RNA guides that allow interference with plasmid DNA (10). *T. thermophilus* Argonaute (*TtAgo*) acquires 5′-phosphorylated single stranded DNA (ssDNA) guides termed small interfering DNAs (siDNAs). These siDNAs are utilized by *TtAgo* to cleave ssDNA and double stranded DNA (dsDNA) targets, the latter by cleaving each of the strands individually (11).

Archaeal pAgos initially have been explored to get insights in structural organization of Argonaute proteins (13,14). Along with the structure of *Archaeoglobus fulgidus* Argonaute (*AfAgo*), which is a truncated pAgo, the binding affinity of *AfAgo* for various nucleic acids has been described (14). The apo-*AfAgo* has a higher affinity for ssDNA and dsDNA molecules than for ssRNA and dsRNA molecules (14). The enzyme of *Methanocaldococcus januschii* (*MjAgo*) is the only archaeal Argonaute of which in vitro activity assays have been reported, revealing that this protein can utilize DNA guides to cleave DNA targets (15). Like *AfAgo*, *MjAgo* binds ssDNA and dsDNA molecules with a much higher affinity than ssRNA and dsRNA molecules (15). Furthermore, *MjAgo* is unable to cleave RNA target strands. The physiological role of *MjAgo* has not been characterized. *MjAgo* belongs to a clade of euryarchaeal thermophilic Argonautes, which is the pAgo clade that is most closely related to the eukaryotic Arg-
onanutes (3,6) (Figure 1A). This clade also contains the *Pyrococcus furiosus* Argonaute (*PfAgo*). *P. furiosus* is a hyperthermophilic archaeon, like *A. fulgidus* and *M. januschii*, and grows optimally at temperatures between 80 and 100°C (16). *PfAgo* was the first Ago whose complete three-dimensional structure was determined (13). However, the physiological role and the molecular mechanism of *PfAgo* have not yet been reported. Despite belonging to the same clade, *PfAgo* has only 28% shared identity with *M/Ago* (BLASTp), which makes it difficult to predict the functionality of *PfAgo* based on sequence homology alone. Furthermore, the closest related pAgo of which the function is determined is bacterial *TrAgo*, that has a query cover of only 38%, and only 24% shared identities with *PfAgo* (BLASTp). In the present study, a combination of *in vivo* and *in vitro* analyses demonstrates that archaeal *PfAgo* is involved in host defense by mediating DNA-guided DNA interference.

**MATERIALS AND METHODS**

**Strains and cultivation**

For *in vivo* experiments, *P. furiosus* strain JFW02 (17) was used, which is referred to in this chapter as Pf u or wild-type. Furthermore two genomic variants of strain JFW02, Pf uAgo (ago knockout strain) and Pf u-ago-O/E (ago overexpression strain) were used (Figure 1; Supplementary Table S1). Strains were cultivated anaerobically in a defined medium with cellobiose as the carbon source (18) at 90°C (Supplementary Table S1). Strains were cultivated anaerobically in a defined medium with cellobiose as the carbon source (18) at 90°C in anaerobic culture bottles or on medium solidified with 1% (w/v) Gelrite (Research product international). For growth of uracil auxotrophic strains, the defined medium was supplemented with uracil to a final concentration of 20 μM.

**Genomic mutants**

Pfu-ago-O/E was generated by transforming an NruI-linearized pHSG298 ago plasmid (Supplementary Table S2) into the wild-type Pf u strain. The plasmid contains the gene encoding *PfAgo* with an upstream *Thermococcus kodakaraensis* csg promoter, flanked by PF1223 and PF1224 gene sequences for homologous recombination. Furthermore, the plasmid encodes TrpA and TrpB with an upstream gdh promoter. The plasmid was constructed by overlap polymerase chain reaction and oligonucleotides used to generate this plasmid are shown in Supplementary Table S3. Two rounds of colony purification was performed by plating 10⁻³ dilutions of transformant cultures onto selective plate medium (without tryptophan) and picking isolated colonies into selective liquid medium. The PfuAgo was created by pop-out marker replacement strategy as described previously (17). The sequences of oligonucleotide used are shown in Supplementary Table S3.

**Transformation experiments**

Plasmid transformation was performed as described previously using 2.5 ng plasmid DNA μl⁻¹ of culture (18). pJFW18 plasmid (19) and a modified pYS3 plasmid (20) were used (Supplementary Table S2). The modified pYS3 plasmid was generated by replacement of the Sim8 cassette of pYS3 by the Pgdh pyrF cassette from pJFW18. The sequences of oligonucleotides used are shown in Supplementary Table S3. The transformation efficiencies reported were calculated as the number of transformed colonies per μg of DNA added.

**PfAgo antibodies and PfAgo immunodetection**

Polyclonal antibodies were raised in chickens against purified (nickel chromatography) N-terminal, 6X His-tagged recombiant *PfAgo* or *Pcsa2* (loading control) proteins as previously described (21). Western blotting was performed by standard procedures. The blots were incubated with polyclonal IgY immune antibodies and HRP-conjugated Anti-IgY secondary antibody (Gallus Immunotech). The protein bands on the blots were detected using an enhanced chemiluminescent substrate for HRP (horse radish peroxidase) activity (GE Life Sciences) and exposure to autoradiography film.

**Sequence and structural alignments**

For the active site residue sequence alignment, previously published alignments were used (3). For structural alignments, structures from *PfAgo* (PDB: 1ZZ5) and *TrAgo* (PDB: 4N47) were loaded in PyMOL. All residues but the MID and PIWI domains were deleted and the remaining residues were aligned with the PyMOL software. For clarity, only residues forming the active site of *PfAgo*, and active site residues of *TrAgo* were displayed.

**PfAgo expression and purification**

A synthetic codon-optimized gene encoding *PfAgo* with an N-terminal Strep(II)-tag was ordered from GenScript USA Inc. and was directionally cloned into expression vector pCDF-1b as indicated in Supplementary Table S2 (pWUR790). Plasmids pWUR791-pWUR796 (Supplementary Table S2) were generated by introducing mutations according to an adapted QuikChange Site-Directed mutagenesis Kit instruction manual (Stratagene) using primers described in Supplementary Table S3. These plasmids were transformed into *Escherichia coli KRX* (Promega) according to the protocol provided by the manufacturer. Strains were cultivated in LB medium containing 50 μg ml⁻¹ streptomycin and 0.4% (w/v) glucose in a shaker incubator at 37°C. After overnight incubation, cultures were centrifuged for 5 min at 4700 g, after which the supernatant was removed. Cell pellets were resuspended in LB medium containing 50 μg ml⁻¹ streptomycin and incubated in shaker incubator at 37°C until an OD₆₀₀ of 0.6–0.8 was reached. Cultures were cold-shocked by incubation in an ice bath for 15 min. *PfAgo* expression was induced by adding isopropyl-b-D-thiogalactoside (IPTG) and L-Rhamnose to a final concentration of 1 mM and 0.1% (w/v), respectively. Expression was continued in a shaker incubator at 20 or 37°C for 16 h. Cells were collected by centrifugation for 15 min at 6000 × g, after which the supernatant was removed. Cells were resuspended in Buffer I (20 mM Tris/HCl pH 8, 1 M NaCl, 2 mM MnCl₂) and disrupted by sonication with a Branson Sonifier B-12 and Branson Converter with a 5 mm...
tip (ten 30 s pulses at 30% power with 30 s pause between pulses). The solution was centrifuged for 30 min at 32 913 × g at 4°C, after which the supernatant was used for purification by Strep-Tactin affinity chromatography (IBA, Germany) with an adapted protocol. Before loading of the supernatant, the Strep-Tactin Sepharose column was equilibrated with Buffer I. After loading, the column was washed 16 CV (column volumes) Buffer I. N-terminally Strep(II)-tagged PfAgo was eluted in Buffer II (buffer I supplemented with 2.5 mM biotin (Sigma-Aldrich)). For purification of PfAgo used in cation preference and cation gradient experiments, no MnCl₂ was added to the purification buffers.

Activity assays
For activity assays, elution fractions containing PfAgo or PfAgoDM and ssDNA guides (Supplementary Table S3) in a 5:1 ratio (protein:guide) in reaction buffer (20 mM Tris·HCl pH 8) and samples were incubated for 15 min at 95°C. After pre-incubation, ssDNA or ssRNA targets (Supplementary Table S3) were added to a final 5:1:1 ratio (protein:guide:target) and incubated for 1 h at 95°C. Final reaction concentrations were 15 mM Tris·HCl pH 8, 250 mM NaCl, 0.5 μM MnCl₂, 1.25 μM protein, 0.25 μM guide and 0.25 μM target. Note that in different experiments incubation temperature, incubation time and salt concentration were varied (indicated in figures of corresponding experiments). For cation preference experiments, PfAgo or PfAgoDM and ssDNA guides (Supplementary Table S3) were mixed in a 5:1 ratio (protein:guide) in reaction buffer to which different cations were added, and incubated for 15 min at 95°C. After pre-incubation, ssDNA targets (Supplementary Table S3) were added to a final 5:1:1 ratio (protein:guide:target) and incubated for 1 h at 95°C. Final reaction concentrations were 15 mM Tris·HCl pH 8, 250 mM NaCl, 0.5 mM metal-Cl₂ (FeCl₂, CoCl₂, CuCl₂, NiCl₂, MgCl₂, MnCl₂, ZnCl₂ or CaCl₂), 1.25 μM protein, 0.25 μM guide, 0.25 μM target. After incubation Loading Buffer (95% (deionized) formamide, 5 mM ethylene-diaminetetraacetic acid, 0.025% sodium dodecyl sulphate, 0.025% Bromophenol blue and 0.025% xylene cyanol) was added in a 1:1 ratio and samples were incubated for 10 min at 95°C before resolving on 15 or 20% denaturing polyacrylamide gels. Nucleic acids were stained using SYBR gold Nucleic Acid Gel Stain (Invitrogen) and visualized using a G:BOX Chemi imager (Syngene).

Guide co-purification
About 1/10 volume Proteinase K (Ambion) and 1/10 volume CaCl₂ (50 mM) were added to 500 pmol purified proteins in Buffer II and samples were incubated for 4 h at 65°C. Nucleic acids were separated from protein content using Roti(R) Phenol/Chloroform/Isomyl alcohol (Carl Roth GmbH). About 1/10 volume 3 M NaAc (pH 5.2) and 10 μl 0.5% linear polyacrylamide was added, before addition of 96% ethanol in a 2:1 ratio (v/v; ethanol:sample). Samples were incubated at −20°C for 2 days and centrifuged for 30 min at 4°C at 20 000 × rpm in a table top centrifuge. Supernatant was removed and the pellet was dried for 10 min at 50°C. The pellet was washed in 70% ethanol, followed by centrifugation for 30 min at 4°C at 20 000 × rpm in a table top centrifuge. Supernatant was removed and the pellet was dried for 10 min at 50°C. The pellet was resuspended in 50 μl MilliQ H₂O. Purified nucleic acids were [γ⁻³²P] ATP labeled with T4 PNK (Thermo Scientific) in exchange or forward labeling reactions, in which 5’ phosphates or 5’ OH groups are labeled, respectively. Nucleic acids were separated from free [γ⁻³²P] ATP using a Sephadex G-25 column (GE). Nucleic acids were incubated with DNase-free RNase A (Thermo Scientific) or RQ1 RNase-free DNase I (Promega) for 1 h at 37°C. Samples were mixed with Loading Buffer in a 1:1 ratio and samples were incubated for 10 min at 95°C. [γ⁻³²P] ATP labeled nucleic acids were resolved on 20% denaturing polyacrylamide gels. Radioactivity was captured from gels using phosphor screens.

RESULTS
PfAgo interferes with plasmid DNA transformation
To elucidate the physiological role of PfAgo in P. furiosus JFW02 (Pfu) (17), an ago knockout strain (PfuΔago) and an ago overexpressing strain (Pfu-ago-O/E) were generated (Figure 1B). Immunoblots demonstrate that PfAgo is expressed in Pfu, while no PfAgo is detected in PfuΔago (Figure 1C). Approximately 200-fold increased levels of full-length PfAgo were detected in the Pfu-ago-O/E strain (Figure 1C). Bacterial TiAgo has previously been described to be involved in host defense by interfering with plasmid transformation (11,12). In the latter studies, transformations were performed using the natural competence system of T. thermophilus, which transports extracellular DNA into the cell (22). P. furiosus JFW02 also has a natural competence system (18). This allowed comparing natural transformation efficiencies of strains Pfu, PfuΔago and Pfu-ago-

(C) Immunoblot analysis of PfAgo (indicated with a black triangle) content in Pfu and PfuΔago with Csa2 protein (indicated with a gray triangle) serving as the internal standard (left panel) or Pfu and Pfu-ago-O/E (right panel). The amount of lysate analyzed is indicated and the asterisk (*) denotes apparent breakdown products observed when PfAgo is overexpressed. (D) Plasmid transformation efficiencies of the P. furiosus strains. Error bars indicate standard deviations of biological triplicates.

O/E. Each strain was transformed with plasmid pJFW18 (19) or with plasmid pYS3 (20). For both plasmids, transformation efficiency is ~1.5 to 2.5-fold higher in PfuΔago compared to wild-type Pfu (Figure 1D, P < 0.001). When PfAgo is overexpressed, the transformation efficiency is lowered even further (Figure 1D, P < 0.001). This demonstrates that archaeal PfAgo lowers competence by interfering with plasmid transformation.

**PfAgo has a DEDH catalytic tetrad**

Target cleavage by Agos is mediated by a conserved DEDX triad, of which the X can be a histidine or an aspartic acid (3) (Figure 2A). Whereas the DDX residues are positioned close together in the available pAgo structures, the glutamic acid (E) is located on a structural sub-domain termed the ‘glutamate finger’ (23). In TiAgo, this finger is located at a distance of 12.8 Å from the catalytic site when no target nucleic acid is bound (unplugged conformation), but it is inserted into the catalytic site (plugged-in conformation) upon target binding (24). To identify the catalytic residues of PfAgo, a sequence alignment (3) and a structural alignment of TiAgo and PfAgo were analyzed (Figure 2A, B). Previously, it was predicted that the catalytic site of PfAgo includes residues D558, D628 and E635 (13). However, E635 is located away from the catalytic site residues of other Agos both in sequence and structural alignments (Figure 2). In contrast, H745 perfectly aligns with catalytic residues from other Agos in both sequences and structures. Like in the structure of unplugged TiAgo, the glutamate finger of PfAgo is unplugged in the structure of PfAgo (Figure 2B). However, the PfAgo glutamate finger encompasses two glutamic acids (E592 and E596). Which of these two gluta-
mate residues is involved in target cleavage is impossible to
deduce from the sequence alignment or from the available
PfAgo structure (unplugged conformation).

To experimentally identify the residues involved in PfAgo
activity, Strep(II)-tagged PfAgo and five predicted catalytic
mutants were heterologously produced in E. coli KRX.
After affinity purification, expressed PfAgo variants were
tested for activity. As both TtAgo and MjAgo (which is
closely related to PfAgo) can utilize DNA guides to cleave
ssDNA targets, we incubated PfAgo with synthetic 5′-
phosphorylated, 21 nt long siDNAs. Subsequently, a syn-
thetic 98 nt ssDNA target was added (Figure 2C and D). Af-
ter 1 h incubation at 95°C with PfAgo and with PfAgoE592A,
all ssDNA target is cleaved (Figure 2D). This indicates that
PfAgo can utilize siDNAs to cleave DNA targets. In con-
trast, PfAgo mutants D558A, E596A, D628A and H745A
show impaired activity (Figure 2D), indicating that the lat-
ter residues form the DEDH catalytic tetrad of
PfAgo.

Requirements for target cleavage by PfAgo

To further determine the prerequisites for PfAgo-mediated
target cleavage, we tested the influence of temperature, salt
concentration and divalent cation type on siDNA-guided
ssDNA cleavage. As a negative control, we used a catalytic
double mutant, PfAgoDM (PfAgoD558A.D628A). For all as-
says, the guide and target shown in Figure 2C were used.
PfAgo is most active in the range from 87 °C to 99.9 °C
(Figure 3A; higher temperatures were not tested). Longer
(16 h) incubations show that PfAgo exhibits some activity
at 37 °C, but not at 20 °C (Figure 3B). PfAgo is active in re-
actions with a NaCl concentration of 50 to 250 mM, whereas
at NaCl concentrations of 500 to 1000 mM the activity is
lowered or absent (Figure 3C; Supplementary Figure S1).
To investigate if PfAgo functions as a multi-turnover pro-
tein PfAgo, siDNAs and ssDNA targets were incubated in a
2.5:1:20 ratio (PfAgo:siDNA:target). PfAgo–siDNA com-
plexes cleave >95% of the 20-fold excess of target DNA
within 30 min in buffer with 250 mM NaCl (Supplemen-
ary Figure S1). To investigate if higher NaCl concentra-
tions inhibit multi-turnover reactions (for example by re-
stricting the release of cleaved target strands) we addition-
ally performed the same experiment at 500 mM and 1 M
NaCl (Supplementary Figure S1). Even after 16 h, no activ-
ity is observed at 1 M NaCl. At 500 mM NaCl the activity
of PfAgo is severely lowered, but it still depletes the 20-fold
excess of target DNA after 16 h, indicating that high NaCl
concentrations do not inhibit the multi-turnover charac-
teristic of PfAgo.

Next, we investigated which divalent cations PfAgo can
utilize to mediate siDNA-guided DNA target cleavage.
PfAgo is able to utilize Mn²⁺ and Co²⁺ as cation, with
Mn²⁺ being a better cation than Co²⁺ (Figure 3D and E).
In contrast to the phylogenetically closely related MjAgo
(15), TrAgo (9,11,24) and eAgos (25), PfAgo is unable to
use Mg²⁺ as cation for its activity (Figure 3D). Also Fe²⁺,
Cu²⁺, Ni²⁺ and Ca²⁺ do not allow siDNA-guided PfAgo
cleavage of ssDNA (Figure 3D). As eAgos have been shown

Figure 2. DEDH catalytic site of PfAgo. (A) Sequence alignment of human AGO2 (hAGO2), TtAgo, MjAgo and PfAgo, adapted from (3). Only regions
containing the DEDH catalytic residues (indicated in red) are shown. PfAgo catalytic residues E592 and E596 are colored orange. (B) TtAgo catalytic
residues DEDD (yellow; PDB: 4N47) aligned to PfAgo catalytic site (black; PDB: 1Z25). Predicted catalytic residues of PfAgo are colored green. (C)

cleavage site, black lines indicate the predicted 5′ and 3′ nucleotide cleavage products. (D) PfAgo and mutants were loaded with a 21 nucleotide long
siDNA and were incubated with a 98 nucleotide ssDNA target in a 5:1:1 molar ratio (PfAgo:guide:target). Products were resolved on a 15% denaturing
polyacrylamide gel. M: ssDNA marker. nt: nucleotide. The ‘Control’ sample contains no protein.
to preferentially bind guides with specific 5’-end nucleotides (26,27), we tested if PfAgo has a preference for a specific 5’-end nucleotide on the siDNA. Like TtAgo, PfAgo is able to utilize siDNAs with different 5’-end nucleotides equally well (Supplementary Figure S2).

**PfAgo is a DNA-guided protein that cleaves DNA targets**

To investigate whether PfAgo acquires specific guides in vivo, we analyzed nucleic acids that co-purify with PfAgo after expression in *E. coli*. No DNA was observed in RNase A-treated samples, whereas in DNase I-treated samples it was observed that RNAs of undefined length co-purify with PfAgo and PfAgoDM (Supplementary Figure S3). The latter is suspected to be non-specifically bound RNA, as has previously been described for purification of TtAgo and TtAgoDM (3). This is supported by the observation that RNAs associate with PfAgo purified in presence and absence Mn²⁺, whereas a divalent cation is required for specific binding of the 5’ end of the guide by pAgos (28). Unfortunately, attempts to identify guides associated with PfAgo expressed in *P. furiosus* were not successful (data not shown).
To investigate if besides ssDNA, ssRNA can also guide P/Pf Ago activity, P/Pf Ago was incubated with 21 nt DNA or RNA guides after which 45 nt ssDNA or ssRNA targets were added (Figure 4A and B). As expected, P/Pf Ago catalyzes siDNA-guided cleavage of complementary DNA targets (Figure 4B). In contrast to Tt Ago, P/Pf Ago does not show siDNA-guided cleavage of RNA targets (Figure 4B). With the RNA guide, we did not observe any P/Pf Ago-mediated cleavage, neither of ssDNA nor of ssRNA targets. This implies that P/Pf Ago only mediates DNA-guided DNA interference. In addition, the DNA guide length range of P/Pf Ago was tested. P/Pf Ago-mediated cleavage of DNA targets is only observed with siDNAs with a length ranging from 15 to at least 31 nt (longer not tested; Figure 4C and D). Tt Ago utilizes siDNAs with a length ranging from 9 to at least 36 nt (longer not tested) (29). As guides with a length of 31 nt are too long for canonical guide binding by Ago, it has been hypothesized that the guide adopts an alternative trajectory to allow 3′ end insertion into the PAZ binding pocket (29). Alternatively, the 3′ end of guide sticks out of the protein, as the nucleic acid-binding channel of Tt Ago is open to the outside (29). Most likely, the same is true for P/Pf Ago.

P/Pf Ago mediates guide-free and siDNA-guided cleavage of dsDNA plasmids

To test whether P/Pf Ago cleaves plasmid DNA, P/Pf Ago was incubated with its expression plasmid pWUR790 (Figure 5A). As incubation of this plasmid at 95°C in the presence of Mn2+ results in degradation of the plasmid (even in the absence of P/Pf Ago), we incubated the reaction mixtures at 75°C for 16 h. Still, the majority of the plasmid DNA is turned to the open circular confirmation under these conditions, even in absence of P/Pf Ago (Figure 5B). Strikingly, pWUR790 is linearized when incubated with P/Pf Ago in absence of guides (Figure 5B). We observed this suspected guide-free P/Pf Ago-mediated cleavage of pWUR790 in buffer with 250 mM NaCl, but not in buffer with 500 mM NaCl (Figure 5B). These findings suggest either that P/Pf Ago cleaves independently of co-purified DNAs or that DNA guides are utilized but the concentration of such co-purified DNA is below the detection limit of the assay. It has previously been demonstrated that in vivo, Tt Ago acquires guides that allow for targeting its expression vector (11). To rule out that this P/Pf Ago activity was guided by co-purified RNA or by co-purified DNA guides that we were unable to detect, we used pWUR704 as target plasmid (Figure 5C). pWUR704 has minimal sequence similarity to the P/Pf Ago expression vector (pWUR790; no sequences longer than 13 consecutive identical base pairs between the two plasmids). After incubation without P/Pf Ago, the plasmid is present both in open circular and supercoiled configuration (Figure 5E, lane 1). When P/Pf Ago is added, supercoiled pWUR704 is linearized even in absence of guides (Figure 5E, lane 2). Like pWUR790 cleavage, this activity is more pronounced at 250 mM NaCl compared to 500 mM NaCl. In contrast, Tt Ago, which co-purified with detectable levels of siDNA, was unable to cleave pWUR704, unless synthetic siDNAs targeting pWUR790 were added (3). Low levels of guide-free P/Pf Ago-mediated nicking of pWUR704 takes place within 1 h incubation at 75°C (Supplementary Figure S4). As P/Pf Ago does not mediate RNA-guided activity within the same time span (Figure 4), it is unlikely that the activity on plasmid DNA is mediated by RNA that co-purified with P/Pf Ago. Instead, these findings suggest that P/Pf Ago has the potential to cleave the plasmid independently of guides.

We next investigated whether siDNAs can guide P/Pf Ago-mediated plasmid cleavage. We loaded P/Pf Ago either with a FW siDNA targeting the (−) strand of pWUR704 or with a RV siDNA targeting the (+) strand of pWUR704 (Figure 5D). P/Pf Ago and P/Pf Ago–siDNA complexes were incubated with plasmid pWUR704 as target, in buffers containing 250 or 500 mM NaCl. Additionally, both P/Pf Agos complexes with FW guides and with RV guides were mixed and incubated with pWUR704. P/Pf Ago loaded with a single siDNA nicks the plasmid DNA, generating open circular plasmids (Figure 5E, lane 3 and 4). Interestingly, reactions to which FW or RV siDNAs are added contain more open circular plasmid compared to the sample to which no siDNA is added, in which plasmids are mostly turned to the linear state. This suggests siDNA loading hinders guide-free P/Pf Ago activity or alternatively that guide-free cleavage of plasmid DNA by P/Pf Ago requires plasmid supercoiling. Incubation of the plasmids with P/Pf Ago–siDNA complexes targeting both strands of the plasmid results in plasmid linearization (Figure 5E, lane 5). Both processes are performed more efficiently in reactions with 250 mM NaCl as compared to reactions with 500 mM NaCl. More efficient cleavage at 250 mM NaCl has also been observed for ssDNA targets (Figure 5C). These findings demonstrate that P/Pf Ago–siDNA complexes can target dsDNA plasmids, resulting in a dsDNA breaks if both strands of the plasmid DNA are targeted.

DISCUSSION

This work describes the first combined in vivo and in vitro characterization of an archaeal Argonaute. P/Pf Ago functions as a DNA-guided DNA endonuclease that requires divalent cations such as Mn2+ or Co2+ for its activity. It utilizes Mg2+ as cation (while Tt Ago does not belong to the Tt Ago family). P/Pf Ago has some interesting characteristics: P/Pf Ago cannot use Mg2+ as cation (while Tt Ago and Mj Ago can (11,15)) and P/Pf Ago–siDNA complexes do not mediate RNA target cleavage (while Tt Ago–siDNA complexes do (9)). The preference for DNA or RNA guides or targets of eAgos, Tt Ago and P/Pf Ago most likely is determined on a structural level. The guide-target duplex binding channel and guide 5′-end
Figure 4. \(Pf\)Ago utilizes 15–31 nt long siDNAs for ssDNA target cleavage. \(Pf\)Ago was incubated with various guides and targets in a 5:1:1 ratio (\(Pf\)Ago:guide:target). Unless otherwise indicated, target cleavage took place at 75°C for 1 h, with 0.5 mM Mn\(^2+\) as cation. Nucleic acids are resolved on denaturing polyacrylamide gels. M: ssDNA marker. (B) \(Pf\)Ago shows only DNA-guided DNA cleavage. (C and D) Both at 95 and 75°C, \(Pf\)Ago-mediated target cleavage is facilitated by siDNAs which are at least 15 nt long. C: control reaction with \(Pf\)AgoDM and 21 nt long siDNA.

Figure 5. Plasmid cleavage by \(Pf\)Ago. (A) pWUR790 expression plasmid. (B) \(Pf\)Ago expressed at 20°C and purified in absence of Mn\(^2+\) cleaves expression plasmid pWUR790. Agarose gels with plasmid targets incubated without protein (lane 1), with \(Pf\)AgoDM (lane 2) and with \(Pf\)Ago (lane 3). M1: 1-kb DNA ladder (New England Biolabs). M2: pWUR790 marker with open circular (OC), linearized (LIN) and supercoiled (SC) pWUR790. (C) pWUR704 target plasmid, target site indicated in gray. (D) Target region (gray) and FW and RV siDNA guides (black). Predicted cleavage sites are indicated with a black triangle. (E) Agarose gels with plasmid targets incubated with \(Pf\)AgoDM (lane 1), with guide free \(Pf\)Ago (lane 2) and with \(Pf\)Ago loaded with FW siDNA, RV siDNA, or both (lane 3–5) in reaction buffer with 250 mM NaCl (left panel) or 500 mM NaCl (right panel). M1: 1 kb GeneRuler marker (Thermo Scientific). M2: pWUR704 marker with open circular (OC), linearized (LIN) and supercoiled (SC) pWUR704.
binding pockets of eAgos are strongly positively charged, allowing RNA guide and target binding. In contrast, the duplex binding channels of PfAgo and PfAgo are much less positively charged and their guide 5′-end binding pockets are hydrophobic (30), possibly excluding the possibility to bind RNA guides. However, this hypothesis requires further investigation before any claims can be made.

We were unable to co-purify siDNA guides from PfAgo heterologously expressed in E. coli KRX. Possibly PfAgo is not able to acquire guides at the low temperatures at which it is expressed (20 or 37°C) or it requires host factors for guide generation and/or loading. Future research should focus on guides associated with PfAgo expressed in P. furiosus. Interestingly, under some conditions, PfAgo appears to cleave dsDNA plasmids in absence of siDNAs, suggesting that PfAgo shows unguided, non-specific nuclease activity (Figure 5). We have observed similar activity for TrAgo under specific conditions (Swarts et al., unpublished results) and hypothesize that unguided dsDNA cleavage might be related to the generation of siDNAs.

We chose to characterize PfAgo as it belongs to the clade of euryarchaeal pAgos, which is the clade of pAgos that is most closely related to eAgos (Figure 1A). eAgos are best known for their RNA-guided RNA cleaving role in RNA interference. Therefore, we predicted that PfAgo possibly was involved in both RNA interference and DNA interference. In contrast, PfAgo solely mediates DNA cleavage in a DNA guide-dependent manner. Strikingly, a recent comment paper cites numerous papers in which DNA binding by eAgo has been described (31). It was suggested that some eAgos might be involved in DNA binding, a hypothesis that requires further investigation. As PfAgo is one of the pAgos most closely related to eAgos, these findings suggest that eAgos were derived from the same ancestors as PfAgo, which might have utilized DNA guides and/or DNA targets as well. Alternatively, the pAgos changed their guide and target specificity multiple times during evolution. Combined, these findings indicate that bacterial and archaeal Argonautes, and possibly even ancient eukaryotic Argonautes, mediate host defense by DNA-guided DNA interference.
