\begin{abstract}
\textbf{Study background:} Staphyloccoci are widespread in nature, mainly found on the skin and mucous membranes. \textit{Staphylococcus aureus} (\textit{S. aureus}) is the key organism for food poisoning due to massive production of heat stable exotoxins. The current study was attempted to investigate the effect of biofield treatment on antimicrobial susceptibility pattern and biochemical characteristics of \textit{S. aureus} (ATCC 25923).

\textbf{Methods:} \textit{S. aureus} cells were procured from MicroBioLogics in sealed packs bearing the American Type Culture Collection (ATCC 25923) number and stored according to the recommended storage protocols until needed for experiments. Revived and lyophilized state of ATCC strains of \textit{S. aureus} were selected for the study. Both revived (Group; Gr. II) and lyophilized (Gr. III) strain of \textit{S. aureus} were subjected to Mr. Trivedi’s biofield treatment. Revived treated cells were assessed on day 5 and day 10 while lyophilized treated cells on day 10 only. After biofield treatment both treated cells were analysed for its antimicrobial sensitivity, minimum inhibitory concentration value, biochemical reactions and biotype number with respect to control (Gr. I).

\textbf{Results:} The antimicrobial susceptibility and minimum inhibitory concentration of \textit{S. aureus} showed significant (86.67\%) alteration in lyophilized cells while no alteration was found in revived treated cells as compared to control. It was observed that overall 37.83\% (eleven out of twenty nine) biochemical reactions were altered in the treated groups with respect to control. Moreover, biotype numbers were substantially changed in revived treated cells. Gr. II (303137, \textit{Staphylococcus capitis} subs. \textit{urealyticus}) on day 5 and in lyophilized treated cells, Gr. III (767177, \textit{S. cohnii} subs. \textit{urealyticum}) on day 10 as compared to control (307016, \textit{S. aureus}).

\textbf{Conclusion:} The result suggested that biofield treatment has significant impact on \textit{S. aureus} in lyophilized treated cells with respect to antimicrobial susceptibility, MIC values and biochemical reactions pattern. Apart from these, biotype numbers with new species were observed in revived treated group on day 5 as \textit{Staphylococcus capitis} subs. \textit{urealyticus} and in lyophilized cells as \textit{Staphylococcus cohnii} subs. \textit{urealyticum} with respect to control, i.e., \textit{S. aureus}.

\section*{Introduction}
Staphylococci (staph) are Gram-positive spherical bacteria that occur in microscopic clusters resembling to grapes like structure. \textit{Staphylococcus aureus} (\textit{S. aureus}) is considered as the third most important cause of food-borne disorders in the world [1]. It is estimated that in US alone food-borne illnesses affect 6 to 80 million people each year, causing up to 9000 deaths [2]. \textit{S. aureus} transmitted mainly through foodstuffs and the important cause of food contamination including milk products and beef [3,4]. \textit{S. aureus} mainly invades through the nasal passages, but it is also found regularly in most other anatomical locales, including the skin, oral cavity and gastrointestinal tract. \textit{S. aureus} has developed resistance to most classes of antimicrobial agents. Penicillin is the drug of choice to treat staphylococcus infection but due to penicillinase or \textit{β}-lactamase enzyme that destroy the penicillin, leads to resistance against \textit{S. aureus} [5]. Therefore, some alternative strategies are needed to treat against resistant strains of staphylococci. Biofield treatment has been known as alternative approach which may be useful to alter the resistance pattern in staphylococcus infected patients.

Afterward, Harold Saton Burr had performed the detailed studies on the correlation of electric current with physiological process and concluded that every single process in the human body had an electrical significance [6]. Recently, it was discovered that all the electrical process happening in body have strong relationship with magnetic field as required by Ampere’s law, which states that the moving charge produces magnetic fields in surrounding space [7,8]. Thus, the human body emits the electromagnetic waves in form of bio-photons, which surrounds the body and it is commonly known as biofield. Therefore, the biofield consists of electromagnetic field, being generated by moving electrically charged particles (ions, cell, molecule etc.) inside the human body. According to Rivera-Ruiz, reported that electrocardiography has been extensively used to measure the biofield of human body [9]. Thus, human has the ability to harness the energy from environment or universe and can transmit into any living or nonliving object(s) around the Globe. The objects always receive the energy and responding into useful way that is called biofield energy and the process is known as biofield treatment. Mr. Mahendra Trivedi’s biofield treatment has been known to transform the structural, physical and thermal properties of several metals in material science [10-12], improved the overall productivity of crops [13,14], altered...

characteristics features of microbes [15-17] and improved growth and anatomical characteristics of various medicinal plants [18,19].

Due to the clinical significance of this organism and literature reports on biofield, the present work was undertaken to evaluate the impact of biofield treatment on \textit{S. aureus} in relation to antimicrobials susceptibility and biotyping based on various biochemical characters.

Materials and Methods

\textit{S. aureus}, American Type Culture Collection (ATCC 25923) strains were procured from MicroBioLogics, Inc., USA, in two sets A and B. Two different sealed packs were stored with proper storage conditions until further use. All the tested antimicrobials and biochemicals were procured from Sigma-Aldrich (MA, USA). The antimicrobial susceptibility, biochemical reactions and biotype number were estimated with the help of MicroScan Walk-Away (Dade Behring Inc., West Sacramento, CA, USA) using Positive Breakpoint Combo 30 (PBPC 30) panel with respect to control group.

Experimental design

Two ATCC 25923 samples A and B of \textit{S. aureus} were grouped (Gr.). ATCC A sample was revived and divided into two parts Gr.I (control) and Gr.II (revived); likewise, ATCC B was labeled as Gr.III (lyophilized).

Biofield treatment strategy

The Gr. I remained as untreated. The treatment Gr. II and III in sealed pack were handed over to Mr. Trivedi for biofield treatment under laboratory condition. Mr. Trivedi provided the treatment through his energy transmission process to the treated groups (Gr. II and Gr. III) without touching the samples. After treatment, all treated samples were handed over in the same condition and stored for analysis. Gr.II was assessed at two time point, \textit{i.e.}, on day 5 and 10 and Gr. III was assessed on day 10. After biofield treatment, all the groups (control and treated) were investigated on day 10 for antimicrobial susceptibility, biochemical reactions pattern and biotyping.

Antimicrobial susceptibility test

Investigation of antimicrobial susceptibility of \textit{S. aureus} was carried out with the help of automated instrument, MicroScan Walk-Away™ using PBPC 30 panel. The tests carried out on MicroScan were miniaturized of the broth dilution susceptibility test that have been estimated with the help of MicroScan Walk-Away™ (Dade Behring Inc., West Sacramento, CA, USA) using Positive Breakpoint Combo 30 panel with respect to control group.

Biochemical reaction studies

Biochemical reactions of \textit{S. aureus} were determined using MicroScan Walk-Away™ system with PBPC 30 panel [21].

Identification of organism by biotype number

The biotype number of \textit{S. aureus} was determined on MicroScan Walk-Away™ processed panel data report with the help of biochemical reactions data [22].

Results and Discussion

Antimicrobial susceptibility test

The outcome of \textit{S. aureus} susceptibility pattern and MIC values of tested antimicrobials after biofield treatment are summarized in Tables 1 and 2, respectively. The data were analyzed and compared with respect to control. Study was carried out in thirty antimicrobials. The treated cells of \textit{S. aureus} showed a significant (86.67%) alteration (twenty six out of thirty) in antimicrobial sensitivity pattern (S to R) and MIC values in the lyophilized treated Gr. III on day 10 as compared with control. Four, out of thirty tested antimicrobials did not show any responses in lyophilized treated cells of \textit{S. aureus}. Out of twenty six antimicrobials two antibiotics (ampicillin and penicillin), \textit{i.e.}, 6.67% did not show any change because \textit{S. aureus} has the ability to produce β-lactamas or penicillinase enzyme which breakdown the β-lactam ring present in penem heteronuclearus [23]. The effect of biofield treatment had revealed that the antibiotic chloramphenicol converted the sensitivity pattern from S → R with corresponding MIC value (≤ 8 to >16 µg/mL) in revived treated cells (Gr. II) and in lyophilized treated cells (Gr. III) on day 10 with respect to control. Three out of thirty (10%) antimicrobials did not show any alteration of MIC values in all the treated groups as compared to control (Table 2). The treated cells

| S. No. | Antimicrobial | Type of Response | Gr. I | Gr. II | Gr. III |
|-------|--------------|-----------------|------|-------|--------|

R: Resistant; S: Susceptible; Gr.: Group; ‘–’ : Not reported; BLAC: Beta lactamase positive

Table 1: Antibiogram of \textit{Staphylococcus aureus}: Effect of biofield treatment on antimicrobial susceptibility.
Biochemical reactions studies

The specific biochemicals showed some changes against *S. aureus* after biofield treatment are shown in Table 3. Similarly, novobiocin, glycosidases, \(\beta\)-lactamas, rambose, sorbitol and glycosidase (PGR and PGT) were changed from negative (−) to positive (+) reaction in lyophilized treated group but remained same, i.e., negative (−) in revived treated cells with respective to control. Voges-Proskauer converted from positive (+) to negative (−) reaction in Gr. II on day 5 with respect to control in biofield treated *S. aureus* cells. Similarly, urea, arginine and MNS were converted from negative (−) to positive (+) reaction in all the groups as compared to control. Crystal violet converted from negative (−) to positive (+) reaction in all the groups with respect to control. Overall, 37.93% biochemical reactions were altered in tested twenty nine biochemicals with respect to control after biofield treatment. In lyophilized strain *S. aureus* after biofield treatment as compared to control.

Identification of organism by biotype number

The species (*S. aureus*) was identified based on variety of conventional biochemical characters and biotyping. Biotype number of particular organism was evaluated after interpreting the results of the biochemical reactions. The biotype number then led to the particular organism identification. In this experiment, biotyping was performed.
using automated systems, results found significant changes in the biofield treated Gr. II (on day 5) and Gr. III (on day 10). Based on the biochemical results, biotype number was changed in treated Gr. II on day 5 (303137, Staphylococcus capitis subsp. ureolyticus) and Gr. III on day 10 (767177, Staphylococcus cohnii subsp. urealyticum) with respect to control (307016), i.e., S. aureus (Table 4).

Due to microbial resistance to a single drug or multiple drugs, invention of an effective antimicrobial therapy for the human-wellness is urgently required. However, due to some limitation of science, the progress of new medications is slow and very challenging for scientists. Mr. Trivedi has the ability to harness energy from environment and altered the significant changes in microorganisms [15,16]. Biofield treatment might be responsible to do alteration in microorganism at genetic level and enzymatic level, which may act on receptor protein. While altering receptor protein, ligand-receptor/protein interactions may alter that could lead to show different phenotypic characteristics [25]. Biofield treatment might induce significant changes in lyophilized strain of S. aureus and altered antimicrobials susceptibility pattern, MIC values, biochemical reactions, and ultimately change the biotype number of microorganism. As a result, the microbe that was susceptible to a particular antimicrobial in control sample now converted into resistant/BLAC in lyophilized treated cells of S. aureus predominately after biofield treatment. Based on these results, it is postulated that, biofield treatment has the ability to alter the sensitivity pattern of antimicrobials.

Conclusions

Altogether, the biofield treatment has significant (86.67%) altered the susceptibility pattern with MIC values of tested antimicrobials against the strain of S. aureus. It also significantly (37.93%) altered the biochemical reactions pattern and biotype number of biofield treated strain of S. aureus. On the basis of changed biotype number after biofield treatment, new species were identified in revived cells as Staphylococcus capitis subsp. ureolyticus and in lyophilized cells as Staphylococcus cohnii subsp. urealyticum with respect to control, i.e., S. aureus. Mr. Trivedi’s biofield treatment could be applied as alternative therapeutic approach against antimicrobial resistance.
