This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the author guidelines.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the ethical guidelines, outlined in our author and reviewer resource centre, still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Minimalistic Supramolecular Proteoglycan Mimics by Co-assembly of Aromatic Peptide and Carbohydrate Amphiphiles

Alexandra Brito,‡a Yousef M. Abul-Haija,cd* Diana S. Costa,‡b Ramon Novoa-Carballal,‡b Rui L. Reis,abc+ Rein V. Ulijn,‖b+ Ricardo A. Piresabc+ and Iva Pashkulevaabc+

We report on the co-assembly of aromatic carbohydrate and dipeptide amphiphiles under physiological conditions as a strategy to generate minimalistic proteoglycan mimics. The resulting nanofibres present a structural, fluorenylmethoxycarbonyl-diphenylalanine (Fmoc-FF) core and a functional carbohydrate (Fmoc-glucosamine-6-sulfate or -phosphate) shell. The size, degree of bundling and mechanical properties of the assembled structures depend on the chemical nature of the carbohydrate amphiphile used. In cell culture medium, these nanofibres can further organize into supramolecular hydrogels. We demonstrate that, similar to proteoglycans, the assembled gels prolong the stability of growth factors and preserve the viability of cultured cells. Our results demonstrate that this approach can be applied to the design of extracellular matrix (ECM) substitutes for future regenerative therapies.

**Introduction**

Molecular self-assembly is a versatile bottom-up approach for design and synthesis of functional biomaterials.1-5 The main advantage of this approach is the possibility to create structural and functional biomimetics with simple and systemically customizable compositions.3-5 As an example, bioactive peptide amphiphiles (PA) of varying complexity have been used as simple functional analogues of various proteins.2,4 These building blocks can code specific biochemical information and transfer it to the surrounding (biological) environment. Glycosylation, the process of functional decoration of proteins with carbohydrates chains, is the most common post-translational modification that diversifies the proteins’ roles by instructing their folding and by activating specific recognition events and different signalling pathways.6 Attached carbohydrate chains can also have a protective role which contributes to the proteins’ stability and activity.6,7 So far, these diverse roles of carbohydrates have received little attention, compared to peptides, in the design of molecular self-assembling blocks for the synthesis of functional supramolecular gels.5,14

Aiming to develop extracellular matrix (ECM) mimics, recent studies introduced the use of peptide amphiphile (PA) end-on functionalized with carbohydrate moieties.8-11 Upon assembly of such amphiphiles, the carbohydrate units are exposed on the surface of the assembled fibre and are able to participate in multivalent biospecific interactions. While this approach seems straightforward for generating supramolecular mimics of proteoglycans, the introduction of the carbohydrate unit is challenging in terms of PA synthesis and assembly as it may disturb the delicate balance of forces governing the process of self-organization.15,16

Multicomponent co-assembly offers a possibility to expand the chemical diversity and functional complexity of the supramolecular systems without compromising the simplicity of the building blocks.17 The feasibility of this approach has been demonstrated by combination of different PAs.15-18 We hypothesized that a similar strategy can be also applied for co-assembly of simple carbohydrate amphiphiles (CAs, 1) and their peptide analogue (2) and the result will be a synergistic modular system mimicking proteoglycans (Scheme 1).

The range of carbohydrates found in biological systems provide a rich library of water soluble, chiral building blocks.19 Simple carbohydrate amphiphiles (CAs) functionalized with aromatic moieties such as naphthalene and fluorenylmethoxycarbonyl (Fmoc) have been recently developed and shown to form self-assembled structures.20-22

However, the amphiphiles bearing naphtalene unit do not form gel and the ones functionalized with Fmoc require a heat-cool cycle or specific enzymatic stimulus to enable the formation of gels at physiological conditions.20, 21

Herein, we describe bi-component systems, in which the fluorenylmethoxycarbonyl-diphenylalanine (Fmoc-FF) provides the structural component, while the Fmoc-carbohydrate is the solvent-exposed functional element, which can be systematically exchanged (Scheme 1). We demonstrate that these modular materials combine the simplicity of small molecules with the versatility and biofunctionality of glycans and proteins, respectively.

Results and Discussion

Self-assembly of aromatic carbohydrate amphiphiles (1) and Fmoc-FF (2)

The amphiphiles Fmoc-glucosamine-6-sulfate (GlcN6S, 1a) and Fmoc-glucosamine-6-phosphate (Fmoc-GlcN6P, 1c) were obtained from the respective glucosamines in a single-step reaction using an excess of Fmoc chloride (details on the synthesis and chemical characterization of the amphiphiles are provided in the SI, Fig. S1-S13).

Fmoc-GlcN (1a) is not soluble in water at room temperature. Upon temperature rising (80 °C), it dissolves and organizes spontaneously into nanofibers that, at room temperature, form a highly hydrated scaffold (Fig. 1A).20 On the other hand, Fmoc-FF (2) dissolves in water only at basic pH (~11) and self-assemble upon pH decrease.23-25 The assembly of 2 is controlled by peptidic hydrogen bonds that results in the formation of β-sheet-like structures that are further stabilized by aromatic π-π interactions, whilst the organization of 1a is driven by a combination of CH-π and π-π (T-shape) stacking interactions.20, 24, 26

We compared the properties of the formed assemblies by AFM (Fig. 1B, C, black outlines) and found that the fibres have similar size but their Young’s moduli are significantly different: the PA 2 assemblies in very rigid fibres (~16 GPa) that have 4-fold higher modulus than the ones obtained from the carbohydrate analogue 1a (~4 GPa).

The co-assembly of 2 and 1a is challenging as both compounds have limited solubility in water and dissolve at different conditions. We functionalized 1a with polar groups aiming to improve the solubility and to impart relevant functionality. Sulphate groups (1b) were chosen because of their biological relevance: most ECM glycosaminoglycans are sulphated and they interact specifically with other biological entities (involved in cell-cell and cell-ECM interactions) depending on their sulphation patterns.6 On the other hand, carbohydrates internalized by cells are activated via their functionalization with phosphate groups and thus, we have also chosen this functionality (1c). As expected, incorporation of these functional groups resulted in improved solubility and...
affected the assembly of Fmoc-GlcN6S (1b) and Fmoc-GlcN6P (1c): the introduced polar, negatively charged groups cause electrostatic repulsion between the modified CA thus, distorting the unidirectional assembly observed for 1a. Such Coulomb forces favour self-assembled morphologies with high surface to volume ratio. Indeed, 1b and 1c form micellar assemblies with negative zeta potential (-112.0 ± 23.7 mV for 1b and -74.4 ± 5.3 mV for 1c), indicating that the sulphate group of 1b and the phosphate group of 1c are displayed on the surface of the micelles formed in water (Fig. 1A). Of note, the micelles of 1c are bigger than the ones assembled from 1b due to the different Coulomb forces (Fig. S17). The circular dichroism (CD) analysis supports the formation of micellar assemblies: no signals were observed in the CD spectra of 1b and 1c (Fig. 1D).

Co-assembly of 2 with either 1b or 1c was performed in water at room temperature. The respective amphiphiles were dissolved at basic pH (~11) at different ratios (i.e. PA:CA of 2:0.5, 2:1, 2:2) but transparent solutions were observed only for the ratios 2:0.5 and 2:1 (Fig. S14). The pH was then adjusted to 8 by drop-wise addition of HCl. CD spectra of these solutions were recorded 24 h after the pH adjustment and indicated formation of assemblies that clearly differ from 2 (Fig. 1D, S18). The peak at 204 nm is associated with π-π* transition and is clearly observable for all systems that contain 2. Formation of a superhelical arrangement (n-π* transition) is shown by the signal at 225 nm in the spectrum of 2.26 A blue shift of this peak, observed in the mixed systems (217 nm for 2/1b and 220 nm for 2/1c), indicates changes in the superhelical structure.28,29 This shift was concomitant with polarity change upon addition of CAs and increased intensity especially for 2/1c, indicating co-assembly of the CAs with 2. Signals associated with the π-π* transition of the Fmoc groups (the signal with maximum at 278 nm and the peak at 306 nm in the spectrum of 2, Fig. 1D) are also blue-shifted in the spectra of the mixed systems confirming co-assembly.27

TEM and AFM characterization corroborated the CD and fluorescence data. The co-assembled fibres differ from the single component fibres in several aspects: both 2/1b and 2/1c fibres are bundled (and appear branched), thicker and less stiff than the Fmoc-FF fibres (Figs. 1A-C and S16, S20). Furthermore, the co-assembled fibres have higher Young’s moduli compared to the single component CA (1a) fibres, i.e. the co-assemblies have intermediate mechanical properties when compared with the PA and CA single component fibres. FTIR spectroscopy was also performed to characterize the co-assemblies (Fig. 1E).30,31 Absorptions at 1625 and 1687 cm⁻¹ are associated with formation of H-bonding by Fmoc-peptide amide and carbamate groups.32 As expected, these peaks are missing in the spectra of CA (1b and 1c) solutions. On the other hand, the amide I peaks are clearly observed for the co-assembled systems (2/1b and 2/1c) demonstrating that the β-sheet structure remains intact in the presence of the CA although the lower intensity of these peaks suggest that a degree of intercalation might have occurred.

Previously, different models for assembly of two-component systems have been proposed.30–32 Our results (AFM; CD and FTIR spectra) indicate that 2 co-assembles with 1b and 1c into core-shell nanofibers with the carbohydrate moieties exposed on the surface. Such co-assembly would involve intercalation between the Fmoc moieties of the CA and PA on the formed fibre surface (Scheme 1B), thus shielding the hydrophobic Fmoc while exposing the carbohydrate unit.31 We studied the surface charge of the formed nanofibers in order to confirm this organization (Table S1). The value determined for 2 was -0.04 mV, which agrees with our previous work showing that the apparent pKₐ of the terminal carboxylic acid in 2 is substantially shifted due to the favoured self-assembly of the uncharged form.23 The co-assembled systems 2/1b and 2/1c have negative zeta potentials, -56.0 ± 1.5 mV and -55.4 ± 6.1 mV respectively. As expected, the absolute values are smaller than the ones of the precursor CAs due to the lower density of the functional groups on the co-assembled fibres as compared with the single component micelles. These results further confirm our hypothesis for co-assembly resulting in the formation of systems with peptide-based core and carbohydrate shell.

Characterization of the supramolecular gels

Upon contact with cell culture medium (pH 7.4), the PA 2 and its co-assemblies with the CAs form self-sustained macroscopic gels (Fig. 2A).

We used AFM to analyse the gels and observed typical entangled fibrous network for all studied compositions (Fig. 2B, S21). However, two major differences can be observed in the AFM images: fibres of 2 are thinner and more entangled compared to the ones generated by co-assembly (2/1b and 2/1c). These differences are also reflected in the viscoelastic properties of the gels: mixed systems form more robust gels in...
all studied media (Fig. 2C, S23). Previous studies have demonstrated that gelation of similar PA systems can be either pH- or salt-triggered via the formation of salt bridges between the anions exposed on the fibres surface (Scheme 1C).33, 34 Our rheological studies confirmed that these stabilizing interactions are also at play in our current system: upon reduction of the pH by adding Dulbecco’s Phosphate-Buffered Saline (DPBS, pH 7.4, only monovalent cations), we observed formation of soft gels. The moduli of the formed gels increased significantly in the presence of divalent Ca<sup>2+</sup> cations (Fig. 2C, DPBS+CaCl<sub>2</sub>). This difference depends on the anions exposed on the fibre surface and we observed the following order HPO<sub>4</sub><sup>2-</sup> (2/1b 3.3-fold increase) > SO<sub>4</sub><sup>2-</sup> (2/1c 3.3-fold increase) > COO<sup>-</sup> (2, 2.7-fold increase). These results confirmed that the carbohydrate units are exposed on the fibres’ surface.

After confirming the exposure of the carbohydrate units on the fibre surface and their ability to form gels under physiological conditions, we evaluated the bioactivity of the generated co-assemblies by their ability to interact specifically with proteins. We designed two experimental setups to evaluate two fundamental roles of proteoglycans in the ECM: the ability of the assembled gels to protect growth factors and to host cells.

**Interactions of the supramolecular gels with basic fibroblast growth factors (FGF-2)**

Basic fibroblast growth factor (FGF-2) is a glycoprotein that has pleiotropic effect in different tissue and organs: it is crucial for processes as angiogenesis, development, wound healing, cell survival and differentiation, among others.35, 36 It is also known for its thermal instability: it loses most of its activity after 24 h of incubation at 37 °C (Fig. S24).37 In its native environment – the pericellular space – FGF-2 interacts specifically with cell surface proteoglycans, which protect it from degradation and aggregation.38 Electrostatic interactions and hydrogen bonding are the main driving forces for the formation of proteoglycan-FGF-2 complexes.6, 38 Proteoglycan charge density is crucial for these interactions as basic amino acid residues in the growth factor, usually ordered in Cardin–Weintraub sequences, are the main contributors to the formation of the complexes.5, 38 Indeed, addition of heparin (the most negatively charged natural biomolecule) or heparan sulphate to the FGF-2 incubation media prolongs its activity37, 39, 40. We therefore tested the developed systems for their capacity to protect FGF-2 and preserve its bioactivity under physiological conditions (Fig. 3).6 We added the growth factor in the gels (details are provided in the SI) and the successful encapsulation was confirmed by immunostaining and SDS-PAGE (Fig 3, OD). Of note, immunostaining allows visualisation only of active FGF-2 as it is based on the recognition of the growth factor by specific antibody with fluorescent tag. The gels with the encapsulated growth factor were maintained at standard cell culture conditions (DMEM at 37 °C) for 7 days and then characterised again (Fig. 3, 7D). Our results demonstrated that mixed systems (2/1b and 2/1c) protect better the FGF-2 from degradation when compared to the non-functionalized peptide nanofibers (2): stronger co-localization (Fig. 3A) and more protein (Fig. 3B) is visible for the FGF-2 loaded in the co-assembled gels after 7 days. Moreover, ELISA tests did not show any release of the growth factor to the surrounding media for this period of time. These results indicate that FGF-2 is simply entrapped in the Fmoc-FF gel and thus, attainable for degradation (although slower as compared with free FGF-2). On the other hand, in the mixed systems, FGF-2 interacts with the carbohydrates exposed on the fibers surface, thus copycattting the natural proteoglycan protection mechanism.
Cytotoxicity of the supramolecular gels

Next, we tested the ability of the gels to support viable cells. Initially, we used L929 cells that are recommended for standard in vitro cytotoxicity tests. Our results demonstrate that cells remain viable either when they are seeded on top of the gels (Figs. 4A, S27) or when they are encapsulated inside the gels (Figs. 4B, S27). Chondrogenic cell line ATDC5 (Fig. S25) and epithelial HeLa cells (Fig. S26) were also tested with the assembled materials to prove their versatility. In all the cases, we observed a majority of viable cells (Fig. S27). The culture of these cell lines requires the use of media supplemented with proteins (10% fetal bovine serum, FBS) that can affect the mechanical properties of the gels.41 Our results demonstrated that indeed the presence of proteins affect significantly the storage moduli of the gels: when DPBS supplemented with CaCl₂ was replaced with DMEM (same Ca²⁺ concentration) supplemented with FBS we observed significant decrease of the storage moduli, especially for the co-assembled systems (Figs. 2C, S23). Of note, the substitution of DMEM by DMEM/F12 does not induce any significant change in the mechanical properties of the gels (Fig. S23). This data suggests that the proteins from the medium interact with the mixed systems and disrupt partially the ionic crosslinking bridges between different nanofiber segments. As the mechanical properties of the assembled gels at cell culture conditions are very similar, we suggest that the observed different number of adherent/encapsulated cells is due to the different chemistry of the generated supramolecular systems and their specific interactions with the cultured cells.

Conclusions

We have successfully designed and synthesized supramolecular, functional glycoprotein mimics by co-assembly of simple building blocks. In spite of the building blocks’ simplicity, the proposed approach has several other advantages: the assembly is carried out under physiological conditions, the formed hydrogels are stable, non-cytotoxic and biofunctional. We also demonstrated that by changing the chemical design in a systematic way we are able to control the biofunctionality and mechanical properties of the supramolecular gels – features that are of key importance in the design of materials for biomedical and tissue engineering applications.

Modular two-component supramolecular hydrogel composed of a peptide core and carbohydrate shell as a minimalistic mimic of proteoglycans.
