Abstract

Let \( F \) be a field of characteristic different from 2 and 3, and let \( V \) be a
vector space of dimension 2 over \( F \). The generic classification of homogeneous
quadratic maps \( f: V \to V \) under the action of the linear group of
\( V \), is given and efficient computational criteria to recognize equivalence
are provided.

Mathematics Subject Classification 2010: Primary 15A72; Secondary 11E88, 12E20,
12E30, 13A50, 15A66.

Keywords: Clifford algebra, homogeneous quadratic map, invariant function, linear
representation, linear group, symmetric bilinear composition law.

1 Introduction

Let \( F \) be a field of characteristic \( p \neq 2,3 \) and let \( V \) be a 2-dimensional \( F \)-vector
space. In this paper we classify homogeneous quadratic maps \( f: V \to V \) that
satisfy certain generic condition to be introduced later. Since there is a natural
bijection between homogeneous quadratic maps on \( V \) and symmetric bilinear
composition laws \( F: V \times V \to V \), the classification is carried out over the latter
considering the action of the general linear group \( GL(V) \).

The topic has not elicited much attention and the literature is scarce. As far
as we know, only our previous work [2] has clearly focused this topic. However,
homogeneous quadratic maps play a major role in the dynamics of discrete
systems (see, for example, [1]) and may give rise to new or revamped one-way
functions potentially interesting for cryptographic applications.

Our purpose in this work is to apply to arbitrary fields the classification
obtained in [2], where such goal was achieved only for the case of an an algebraically closed field. However, it will become apparent along the coming
sections that the methods employed to classify in the latter case are no longer applicable. Actually, the main role for the present case is played by the Clifford algebra associated to the quadratic form defining the symmetric bilinear law. In particular, this new tool has allowed us to to deal with both the hyperbolic and the elliptic cases of the quadratic form under a unified framework. We want to stress that the new methods are totally different from those used in \[2\] so that the present contribution cannot be qualified as a plain generalization or extension of the former one.

The main results of the paper can summarized as follows: We give both the general form of any symmetric bilinear law such that its associated quadratic form takes the value \(-1\), and the explicit expression for the maps in the group of isometries. It turns out that such maps are parametrized by an element of the Clifford algebra whose Clifford norm is \(1\). Next we compute the isotropy group, which is discrete. Last, in order to perform the classification, we resort to the invariants computed in \[2\] transposed to the case we are dealing with now. While it is true that this technique do not provide a perfect classification, we do supply efficient computational criteria, allowing one to recognize such equivalence.

We stick here, as we did in \[2\], to the case of a 2-dimensional vector space \(V\). The reason will become clear, since the deployed techniques are deeply connected and tools in order to achieve the classification. In a sense, the procedure shows a kind of “artistic” flavor that renders it not immediately or easily exportable to higher dimensions.

The paper is organized as follows: after a first section explaining some preliminaries and notation, we focus on the topic of Clifford algebras, making it apparent the role played by them in the present work; next we classify generic symmetric bilinear laws, followed by the computation of the isotropy group; finally we undertake the task of computing the criteria to recognize the equivalence of symmetric bilinear laws.

## 2 Preliminaries and notation

If \((v_1, v_2)\) is a basis for \(V\), then \(f(x) = f_1(x)v_1 + f_2(x)v_2\) where

\[
\begin{align*}
  f_1(x_1, x_2) &= a_1(x_1)^2 + 2b_1 x_1 x_2 + c_1(x_2)^2, \\
  f_2(x_1, x_2) &= a_2(x_1)^2 + 2b_2 x_1 x_2 + c_2(x_2)^2, \\
  a_i, b_i, c_i &\in \mathbb{F}, 1 \leq i \leq 2,
\end{align*}
\]

As \(p \neq 2\), there is a natural bijection between homogeneous quadratic maps on \(V\) and symmetric bilinear composition laws \(F: V \times V \to V, F(x, y) = x \star y\) (in short: SBLs), which is given by the polarization formula, e.g., see \[4\] XV, §§2–3]. Remember that two bilinear laws \(*: (x, y) \in V^2 \mapsto x \star y \in V\) and \(\circ: (x, y) \in (V')^2 \mapsto x \circ y \in V'\) are isomorphic—or \(GL(V)-equivalent—if and only if there is a vector-space isomorphism \(u: V \cong V'\) such that, \(\forall (x, y) \in V^2, u(x) \circ u(y) = u(x \star y)\).

If \(V, V'\) are two \(\mathbb{F}\)-vector spaces, the space of bilinear maps is denoted by \(L^2(V, V')\), with the natural identification \(L^2(V, V) \cong L(V \otimes V, V) \cong \otimes^2 V^* \otimes V\). Hence, the classification problem that we tackle transforms into a classification problem in the subspace of symmetric tensors of type \((1, 2)\) on the plane, \(S^2 V^* \otimes\)
$V \subset \otimes^2 V^* \otimes V$. The natural action of the linear group $GL(V)$ on $S^2 V^* \otimes V$ is given by

$$\forall x, y \in V, F \in S^2 V^* \otimes V, \forall u \in GL(V), (u \cdot F)(x, y) = u(F(u^{-1}(x), u^{-1}(y))).$$

Let $(v_1^*, v_2^*)$ be the dual basis of $(v_1, v_2)$; i.e., $v_i^*(v_j) = \delta_{ij}$. Every $F \in S^2 V^* \otimes V$ is written as

$$F = v_1^* \otimes v_1^* \otimes (a_1 v_1 + a_2 v_2) + (v_1^* \otimes v_2^* + v_2^* \otimes v_1^*) \otimes (b_1 v_1 + b_2 v_2) + v_2^* \otimes v_2^* \otimes (c_1 v_1 + c_2 v_2),$$

or matricially,

$$F(x, y) = \begin{pmatrix} a_1 & b_1 & y_1 \\ b_1 & c_1 & y_2 \\ y_1 & y_2 & 0 \end{pmatrix},$$

$$x = x_1 v_1 + x_2 v_2, y = y_1 v_1 + y_2 v_2.$$

Let $\text{tr}: S^2 V^* \otimes V \to V^*$ be the trace mapping. From (2) we obtain

$$\text{tr} F = (a_1 + b_2) v_1^* + (b_1 + c_2) v_2^*.$$

The homomorphism $F \in S^2 V^* \otimes V \mapsto \text{tr} F \in V^*$ is proved to be $GL(V)$-equivariant. For a given $x \in V$, let $F_x: V \to V$ be the $F$-linear endomorphism

$$\forall y \in V, \quad F_x(y) = F(x, y).$$

For each bilinear symmetric map $F: V \times V \to V$, let $q_F: V \to \mathbb{F}$ be the quadratic form defined by $q_F(x) = \det(F_x)$, where $F_x$ is the endomorphism defined in (4).

As a computation shows,

$$q_F(x) = (x_1, x_2) \begin{pmatrix} a_1 b_2 - a_2 b_1 & \frac{1}{2} (a_1 c_2 - a_2 c_1) \\ \frac{1}{2} (a_1 c_2 - a_2 c_1) & b_1 c_2 - b_2 c_1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}
= (a_1 b_2 - a_2 b_1) (x_1)^2 + (a_1 c_2 - a_2 c_1) x_1 x_2 + (b_1 c_2 - b_2 c_1) (x_2)^2,$$

$F$ being given as in (2) and $x = x_1 v_1 + x_2 v_2$.

3 The Clifford algebra of $q_F$

First of all, let $\ast$ be a non-degenerate traceless SBL on $V$, with associated symmetric bilinear map $F: V \times V \to V$, and let $q = q_F$ be the quadratic form introduced in the section 2.

Given $x \in V$, the Cayley-Hamilton theorem yields $(F_x)^2 = -q(x) \cdot \text{id} V$, where $F_x$ is the endomorphism defined in [4]. Hence, by the universal property of the Clifford algebra (e.g., see [4] XIX, section 4), the linear map

$$i: V \to \text{End}(V), \quad i(x) = F_x, \quad \forall x \in V,$$

extends to a homomorphism $\bar{i}: C(-q) \to \text{End}(V)$ from the Clifford algebra of $-q$ to $\text{End}(V)$. Since $-q$ is non-degenerate with dimension 2, the algebra $C(-q)$ is central simple (e.g., see [4] Proposition 11.6–(1))]; hence $\bar{i}$ is injective, and since
dim End(V) = 4 = dim C(−q), we actually conclude that \( \tilde{\iota} \) is an isomorphism of \( \mathbb{F} \)-algebras.

Moreover, \( C_0(−q) \) is a quadratic \( \mathbb{F} \)-algebra and according to [6] Proposition 12.1], the form \( −q \) represents 1, i.e., \( q \) represents \(-1\).

Consequently, a non-degenerate quadratic form \( Q: V \to \mathbb{F} \) is of the form \( Q = q_F \) for some \( F \) if and only if \( Q \) takes the value \(-1\). If \( \mathbb{F} \) is a finite field, then every quadratic form of rank \( \geq 2 \) on \( \mathbb{F} \) takes any value of \( \mathbb{F}^* \) (see [6] 1.7. Proposition 4), but this does not necessarily happen in an arbitrary field.

Let \( x \mapsto \bar{x} \) be the conjugation in the Clifford algebra \( C(−q) \); it is the unique anti-automorphism of \( C(−q) \) that restricts to \( x \mapsto −x \) on \( V \). As \( q \) is a 2-dimensional form, it is known that the map \( x \mapsto N(x) = x \cdot \bar{x} \) is multiplicative, maps into the ground field \( \mathbb{F} \) and extends \( q \): This is the Clifford norm. Next, we choose \( v_1 \in V \) such that \( q(v_1) = −1 \), leading to \( N(v_1) = −1 \). We consider the linear isomorphism \( u: V \xrightarrow{\cong} C_0(−q) \), \( u(x) = v_1 \cdot x, \forall x \in V \), which is actually an isometry from \( (V, q) \) to \( (C_0(−q), N) \). A new SBL \( \circ \) is defined on \( C_0(−q) \) as follows: \( x \circ y = u(u^{-1}(x) \ast u^{-1}(y)), \forall (x, y) \in C_0(−q)^2 \). Hence, \( (C_0(−q), \circ) \) is isomorphic to \( (V, F) \), and its associated quadratic form is \( N \). As \( −q \) represents 1, there exists an orthogonal basis \( (v_1, v_2) \) with respect to the symmetric bilinear form attached to \( q \), such that,

\[
q(v_1) = −1, \quad q(v_2) = −β, \quad \text{for some } β \in \mathbb{F}^*.
\]

Accordingly, \( C(−q) = \langle 1, v_1, v_2, v_1 \cdot v_2 \rangle \) over \( \mathbb{F} \), where the dot denotes the Clifford product, and \((v_1 \cdot v_2) \cdot (v_1 \cdot v_2) = −β.\)

1. If \( x = x_0 + x_1 v_1 + x_2 v_2 + x_{12}(v_1 \cdot v_2), \bar{x} = x_0 − x_1 v_1 − x_2 v_2 − x_{12}(v_1 \cdot v_2), \)

then, \( x \cdot \bar{x} = (x_0)^2 − (x_1)^2 − β(x_2)^2 + β(x_{12})^2.\)

### 4 Classification of SBLs

**Proposition 4.1.** Every SBL on \( C_0(−q) \) can be written in the following form:

\[
F_{abc}(x, y) = a \cdot x \cdot y + b \cdot (\bar{x} \cdot y + x \cdot \bar{y}) + c \cdot \overline{xy}, \quad \forall x, y \in C_0(−q),
\]

for some \((a, b, c) \in C_0(−q)^3\).

**Proof.** We have \( C_0(−q) = \{x = x_0 + x_{12}(v_1 \cdot v_2) : x_0, x_{12} \in \mathbb{F} \} \). Hence the elements of degree zero of the Clifford algebra admit the basis \( \{1, v_1 \cdot v_2\} \).

The mappings \((7)\) are obviously \( \mathbb{F} \)-bilinear and symmetric, since the Clifford product is \( \mathbb{F} \)-bilinear and the conjugation \( x \mapsto \bar{x} \) is an \( \mathbb{F} \)-linear anti-automorphism. Letting \( a = a_0 + a_{12}(v_1 \cdot v_2), b = b_0 + b_{12}(v_1 \cdot v_2), c = c_0 + c_{12}(v_1 \cdot v_2), \) it follows that the mappings \( F_{abc} \) depend on the 6 parameters \( a_0, a_{12}, b_0, b_{12}, c_0, c_{12}. \) As \( \dim(S^2V^* \otimes V) = 6 \), we can conclude.

The equations of the isomorphism \( u: V \xrightarrow{\cong} C_0(−q) \), \( u(x) = v_1 \cdot x, \forall x \in V \), where \( x = x_1 v_1 + x_{12} v_2 \in V \) (introduced in the section \([5]\) and those of its inverse are the following:

\[
u(x) = x_1 + x_2 (v_1 \cdot v_2), \quad u^{-1}(x_0 + x_{12}(v_1 \cdot v_2)) = x_0 v_1 + x_{12} v_2.\]

In what follows, we shall identify the mappings \( F_{abc} \) and \( F = u^{-1} \circ F_{abc} \circ (u, u). \) As a computation shows, we have the following formulas:
By replacing these formulas into (5), it follows:

\[
\begin{pmatrix}
  a_1 & b_1 \\
  b_1 & c_1 \\
  a_2 & b_2 \\
  b_2 & c_2
\end{pmatrix}
= 
\begin{pmatrix}
  a_0 + 2b_0 + c_0 & -\beta (a_{12} - c_{12}) \\
  -\beta (a_{12} - c_{12}) & -\beta (a_0 - 2b_0 + c_0)
\end{pmatrix}
\begin{pmatrix}
  a_0 - c_0 \\
  -\beta (a_{12} - 2b_{12} + c_{12})
\end{pmatrix}.
\]

Theorem 4.2. The SBLs on \(C_0(-q)\) with attached quadratic form \(N\) are the maps of the form \(F_{a,c}(x, y) = a \cdot x \cdot y + c \cdot x^2 + y^2\), for some \((a, c) \in C_0(-q) \times C_0(-q)\) with \(N(c) = N(a) = 1\).

If \(G = \{ \lambda \in C_0(-q) : N(\lambda) = 1 \}\), then two mappings \(F_{ac}\) and \(F'_{a',c'}\) are isomorphic if and only if there exists \(\lambda \in G\) such that \((a', c') = (\lambda^{-1} a, \lambda^3 c)\) or \((a', c') = (\lambda^{-1} a, \lambda^3 c)\).

Proof. According to (8) we have

\[
\begin{align*}
a_1 &= a_0 + 2b_0 + c_0, & b_1 &= -\beta (a_{12} - c_{12}), & c_1 &= -\beta (a_0 - 2b_0 + c_0), \\
a_2 &= a_{12} + 2b_{12} + c_{12}, & b_2 &= a_0 - c_0, & c_2 &= -\beta (a_{12} - 2b_{12} + c_{12}).
\end{align*}
\]

By replacing these formulas into (8), it follows:

\[
\begin{align*}
eq 1 & \equiv a_1 b_2 - a_2 b_1 \\
&= (a_0)^2 + \beta (a_{12})^2 + 2a_0 b_0 + 2\beta a_{12} b_{12} - 2b_0 c_0 - 2\beta b_{12} c_{12} \\
&\quad - (c_0)^2 - \beta (c_{12})^2, \\
eq 2 & \equiv \frac{1}{2} (a_1 c_2 - a_2 c_1) \\
&= 2\beta a_0 b_{12} - 2\beta a_{12} b_0 + 2\beta b_{12} c_0 - 2\beta b_0 c_{12}, \\
eq 3 & \equiv b_1 c_0 - b_2 c_1 \\
&= \beta (a_0)^2 + \beta^2 (a_{12})^2 - 2\beta a_0 b_0 - 2\beta^2 a_{12} b_{12} + 2\beta^2 b_{12} c_{12} + 2\beta b_0 c_0 \\
&\quad - \beta (c_0)^2 - \beta^2 (c_{12})^2.
\end{align*}
\]

Hence

\[
\begin{align*}
eq 1 &= -1, & \quad \eq 2 = 0, & \quad \eq 3 = -\beta.
\end{align*}
\]

Dividing \(\eq 2 = 0\) by \(2\beta\) and \(\eq 3 = -\beta\) by \(\beta\) we obtain

\[
\begin{align*}
(a_0)^2 + \beta (a_{12})^2 + 2a_0 b_0 + 2\beta a_{12} b_{12} - 2b_0 c_0 - 2\beta b_{12} c_{12} - (c_0)^2 - \beta (c_{12})^2 &= -1, \\
a_0 b_{12} - a_{12} b_0 + b_{12} c_0 - b_0 c_{12} &= 0, \\
(a_0)^2 + \beta (a_{12})^2 - 2a_0 b_0 - 2\beta a_{12} b_{12} + 2\beta b_{12} c_{12} + 2b_0 c_0 - (c_0)^2 - \beta (c_{12})^2 &= -1.
\end{align*}
\]

By adding and subtracting the first and third equations above and dividing the result by 2,

\[
\begin{align*}
a_0^2 + \beta a_{12}^2 - c_0^2 - \beta c_{12}^2 + 1 &= 0, \\
a_0 b_0 - b_0 c_0 + \beta a_{12} b_{12} - \beta b_{12} c_{12} &= 0.
\end{align*}
\]

Accordingly, the system (9) is equivalent to

\[
\begin{align*}
e_1 &\equiv (a_0)^2 + \beta (a_{12})^2 - (c_0)^2 - \beta (c_{12})^2 + 1 = 0, \\
e_2 &\equiv a_0 b_{12} - a_{12} b_0 + b_{12} c_0 - b_0 c_{12} = 0, \\
e_3 &\equiv a_0 b_0 - b_0 c_0 + \beta a_{12} b_{12} - \beta b_{12} c_{12} = 0.
\end{align*}
\]
which we use in what follows, because it is easier than the first one. The equation $e_1$ can equivalently be written as

$$N(c) - N(a) = 1. \tag{10}$$

Furthermore, the equations $e_2 = e_3 = 0$ are linear in $b_0$ and $b_{12}$ and they can be written in matrix notation as

$$\begin{pmatrix} -a_{12} - c_{12} & a_0 + c_0 \\ a_0 - c_0 & \beta(a_{12} - c_{12}) \end{pmatrix} \begin{pmatrix} b_0 \\ b_{12} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}. \tag{11}$$

The determinant of the matrix of the system \((11)\) is equal to

$$e_4 \equiv (c_0)^2 + \beta(c_{12})^2 - (a_0)^2 - \beta(a_{12})^2 = N(c) - N(a) = 1,$$

by virtue of \((10)\); hence $e_4$ cannot vanish. Therefore, $b_0 = b_{12} = 0$.

Finally, let us determine the conditions under which $F_{a,c}$ and $F_{a',c'}$ are isomorphic. As is known, any isomorphism between them must be an isometry of $(C_0(-q), N)$, and these isometries are the group $G$ of the maps that have one of the following forms:

$$\begin{align*}
(i) & \quad x \mapsto \lambda x, \\
(ii) & \quad x \mapsto \lambda \bar{x},
\end{align*} \quad \forall x \in C_0(-q), \forall \lambda \in G. \tag{12}$$

Letting $x' = \lambda x$, $y' = \lambda y$, $z' = \lambda z$ into the equation

$$z' = F_{a',c'}(x', y') = a' x' y' + c' \bar{x}' \bar{y}' \tag{13},$$

we obtain $\lambda z = a'(\lambda x)(\lambda y) + c'(\lambda x)(\lambda y)$; hence $z = \lambda a' x y + \lambda^3 c' \bar{x} \bar{y}$, as $\lambda^{-1} = \bar{\lambda}$ (because $N(\lambda) = N(\bar{\lambda}) = 1$) and comparing it with the original equation, i.e., $z = F_{a,c}(x, y) = a x y + c \bar{x} \bar{y}$, we deduce $a' = \lambda^{-1} a$, $c' = \lambda^3 c$. Similarly, letting $x' = \lambda \bar{x}$, $y' = \lambda \bar{y}$, $z' = \lambda \bar{z}$ into \((13)\), we obtain $\lambda \bar{z} = a'(\lambda \bar{x})(\lambda \bar{y}) + c'(\lambda \bar{x})(\lambda \bar{y})$; hence $\bar{z} = \lambda a' \bar{x} \bar{y} + \lambda^3 c' \bar{x} \bar{y}$ and conjugating, $z = \lambda a x y + \lambda^3 c \bar{x} \bar{y}$. Therefore it follows: $a = \lambda a'$, $c = \lambda^3 c'$, or equivalently, $a' = \lambda^{-1} a$, $c' = \lambda^3 c$, thus concluding the proof.

5 Isotropy

Next, we discuss the index of $q$. The quadratic form $q$ is said to be hyperbolic if $q$ admits an isotropic vector $v_1 \neq 0$. If $q$ does not admit any non-zero isotropic vector, then $q$ is said to be elliptic; in this case, as we have seen above, there exists a basis $(v_1, v_2)$ for $V$ such that, $q(x) = -(x_1)^2 - \beta(x_2)^2$, where $-\beta \not\in \mathbb{F}^\times$.

If the discriminant of $q$ is different from $1$ mod $\mathbb{F}^\times$, then $q$ is elliptic, and if the discriminant of $q$ is equal to $1$ mod $\mathbb{F}^\times$, then $q$ is hyperbolic.

With the same notations as in the section 3 we have $(v_1 \cdot v_2)^2 + \beta = 0$. The $F$-algebra $C_0(-q)$ being quadratic, we deduce $C_0(-q) \cong \mathbb{F}[t]/(t^2 + \beta)$ (e.g., see Example 98.2). Hence, in the hyperbolic case, $C_0(-q) \cong \mathbb{F} \times F$, and in the elliptic case $C_0(-q)$ is a quadratic field extension of the ground field $F$.

**Lemma 5.1.** If $q$ is hyperbolic, then the set of zero divisors in $C_0(-q)$ coincides with the set of elements of norm zero.
Proof. If \( N(x) = x \cdot \bar{x} = 0 \), then \( x \) is a zero divisor obviously. Conversely, if \( x, y \in C_0(−q) \) are such that \( x \neq 0, y \neq 0 \), and \( x \cdot y = 0 \), then we obtain the following homogeneous linear system:

\[
\begin{pmatrix}
x_0 \\
x_{12} \\
x_0
\end{pmatrix}
- \beta
\begin{pmatrix}
x_{12} \\
x_0
\end{pmatrix}
= \begin{pmatrix}
y_0 \\
y_{12}
\end{pmatrix}
= \begin{pmatrix}
0 \\
0
\end{pmatrix}.
\]

Since

\[
\det \begin{pmatrix}
x_0 \\
x_{12} \\
x_0
\end{pmatrix}
- \beta
\begin{pmatrix}
x_{12} \\
x_0
\end{pmatrix}
= N(x), \quad y \neq 0,
\]

we can conclude the statement. \( \square \)

Below we compute the isotropy subgroup \( G(F_{ac}) \subset G \) of the mapping \( F_{ac} \) in Theorem 4.2.

We denote by \( \phi_\lambda(x) = \lambda x, \psi_\lambda(x) = \lambda \bar{x}, \lambda \in G, x \in C_0(−q) \), the transformations (i) and (ii) respectively in the formula (12). As a computation shows, we obtain

\[
\phi_\lambda \circ \phi_\mu = \phi_{\lambda \mu}, \quad \phi_\lambda \circ \psi_\mu = \psi_{\lambda \mu}, \quad \psi_\lambda \circ \psi_\mu = \phi_{\lambda \mu}, \quad \forall \lambda, \mu \in G.
\]

In particular \( \psi_\lambda \circ \psi_\lambda = \phi_{\lambda \lambda} = \text{id} \), \( \forall \lambda \in G \); i.e., every transformation in (ii) is involutive.

**Proposition 5.2.** With the previous notations, we have

1. If \( N(a) \neq 0 \) and \( ca^3 \notin \mathbb{F} \), then \( G(F_{ac}) = \{\text{id}\} \).
2. If \( N(a) \neq 0 \) and \( ca^3 \in \mathbb{F} \), then \( G(F_{ac}) = \{\text{id}, \psi_{\frac{1}{2}}\} \).
3. If \( N(a) = 0 \), then \( G(F_{ac}) = \{\phi_\lambda, \psi_\mu : \lambda^3 = 1, \mu^3 = c^2\} \).

**Proof.** If one of the transformations (i) or (ii) in the formula (12) belongs to \( G(F_{ac}) \), then either (i) \( \lambda a = a, c = \lambda^3 c \), or (ii) \( \lambda a = \bar{a}, c = \lambda^3 \bar{c} \). We distinguish several cases.

Assume the item (i) holds.

1. If \( q \) is elliptic, then \( a \neq 0 \) implies \( \lambda = 1 \), as \( C_0(−q) \) is a field, and \( a = 0 \) implies \( \lambda^3 = 1 \), because in this case \( c \) is invertible, as follows from (10).

2. If \( q \) is hyperbolic, i.e., \( \beta = −\gamma^2, \gamma \in \mathbb{F}^* \), then by applying Lemma 5.1 to the equation \((\lambda - 1)a = 0\) it follows that either \( \lambda = 1 \) or \( N(a) = 0 \). In the second case \( c \) is invertible in \( C_0(−q) \) by virtue of (10); hence \( \lambda^3 = 1 \). If \( N(a) \neq 0 \), then the equation \((\lambda - 1)a = 0\) implies \( \lambda = 1 \).

If \( q \) is elliptic, then \( N(a) = 0 \) if and only if \( a = 0 \). Therefore, we can group the two previous items saying that the transformations of type (i) in (10) that belong to \( G(F_{ac}) \) are as follows: If \( N(a) \neq 0 \), then such transformations reduce to the identity map, and if \( N(a) = 0 \), then they correspond to the values \( \lambda \in G \) such that \( \lambda^3 = 1 \).

Assume the item (ii) holds.

From \( \lambda a = \bar{a} \) it follows \( \lambda a^2 = N(a) \).

If \( N(a) = 0 \), then \( a = 0 \), as \( \lambda \) is invertible and \( C_0(−q) \) has no nilpotent element. In this case \( N(c) = 1 \) and from \( c = \lambda^3 \bar{c} \) it follows \( \lambda^3 = c^2 \).
• If \( q \) is elliptic, the equation \( \lambda^3 = c^2 \) may admit none (if \( c^2 \) is not a cube in \( C_0(-q) \)), one (if \( c^2 \) is a cube in \( C_0(-q) \) and \(-3\) is not a square in \( C_0(-q) \)) or three solutions in \( C_0(-q) \) (if \( c^2 \) is a cube in \( C_0(-q) \) and \(-3\) is a square in \( C_0(-q) \)).

• If \( q \) is hyperbolic, then by considering the isomorphism

\[
\phi: \mathbb{F}[t]/(t^2 - \gamma^2) \to \mathbb{F} \times \mathbb{F},
\]

\[
\phi(u + v\tau) = (u - v\gamma, u + v\gamma),
\]

\( u, v \in \mathbb{F}, \; \tau = t \mod(t^2 - \gamma^2), \)

and by writing \( \phi(w) = (w_1, w_2) \), it follows that the equation \( \lambda^3 = c^2 \) is equivalent to the pair of equations \( (\lambda_1)^3 = (c_1)^2 \), \( (\lambda_2)^3 = (c_2)^2 \) in \( \mathbb{F} \). As \( N(c) = N(\lambda) = 1 \), we have \( \lambda_1\lambda_2 = c_1c_2 = 1 \), and the equation \( (\lambda_2)^3 = (c_2)^2 \) is equivalent to \( (\lambda_1)^3 = (c_1)^2 \). Hence even in the hyperbolic case the number of solutions to \( \lambda^3 = c^2 \) may be 0, 1 or 3.

If \( N(a) \neq 0 \), then \( \lambda = \frac{a}{3} \) and replacing this value into the second equation in (ii) we obtain \( a^3c = \alpha^3c \), or equivalently \( a^3c \in \mathbb{F} \).

In summary, the transformations of type (ii) in (10) that belong to \( G(F_{ac}) \) are as follows:

• If \( N(a) = 0 \), then such transformations correspond to the values \( \lambda \in G \) such that \( \lambda^3 = c^2 \), whether \( q \) is elliptic or hyperbolic.

• If \( N(a) \neq 0 \), then such transformations do not exist, except when \( ca^3 \in \mathbb{F} \), in which case the only transformation of type (ii) in \( G(F_{ac}) \) corresponds to \( \lambda = \frac{a}{3} \).

Accordingly, we have

\[
(i) \begin{cases} 
N(a) \neq 0, & \{\text{id}\} \\
N(a) = 0, & \{\lambda \in G : \lambda^3 = 1\}
\end{cases}
(ii) \begin{cases} 
N(a) \neq 0 & \begin{cases} 0, & \text{if } ca^3 \notin \mathbb{F} \\
\lambda = \frac{a}{3}, & \text{if } ca^3 \in \mathbb{F}
\end{cases} \\
N(a) = 0, & \{\lambda \in G : \lambda^3 = c^2\}
\end{cases}
\]

Putting together transformations of type (i) and type (ii), the statement follows. □

6 The role of the invariants

Let \( \sigma: V^* \to S^2V^* \otimes V \) be the map defined by,

\[
\sigma(v^*)(x, y) = \frac{1}{2}(v^*(x)y + v^*(y)x), \; x, y \in V, \; v^* \in V^*.
\]

By using formula (1), the homomorphism \( \sigma \) is proved to be a \( GL(V) \)-equivariant section of \( \operatorname{tr} \). If \( v^* = \lambda_1 v_1^* + \lambda_2 v_2^* \), then from (16) it follows:

\[
\sigma(v^*)(v_1, v_1) = \frac{2}{3} \lambda_1 v_1,
\]

\[
\sigma(v^*)(v_2, v_2) = \frac{2}{3} \lambda_2 v_2,
\]

\[
\sigma(v^*)(v_1, v_2) = \frac{1}{3}(\lambda_1 v_2 + \lambda_2 v_1).
\]
Therefore, there is a decomposition of $GL(V)$-modules $S^2V^* \otimes V = W \otimes \sigma(V^*)$, where $W = \{ F \in S^2V^* \otimes V : \text{tr} F = 0 \}$.

For every $F \in S^2V^* \otimes V$ we set $\tilde{F} = F - \sigma(\text{tr} F)$. Then, $F$ is said to be regular if the quadratic form $Q_F$ is non-degenerate.

A simple computation proves that $F$ is regular if and only if the following condition holds:

$$\begin{align*}
\det Q_{\tilde{F}} &= \frac{1}{12} \cdot a_1 b_1 b_2 c_2 - \frac{1}{6} a_1 a_3 b_1 c_1 + \frac{3}{2} a_2 b_1 b_2 c_1 + \frac{1}{6} a_1 a_2 c_1 c_2 \\
&- \frac{1}{2} a_2 b_1 c_1 c_2 - \frac{1}{2} (a_1)^3 c_1 + \frac{1}{2} (a_1)^2 (b_1)^2 + \frac{1}{12} (a_1)^2 (c_2)^2 \\
&+ \frac{1}{2} (b_2)^3 c_1 + \frac{1}{2} (b_2)^2 (b_1)^2 + \frac{1}{2} (b_2)^2 (c_2)^2 + \frac{1}{2} (a_2)^3 c_2 \\
&- \frac{1}{2} a_2 (c_2)^3 - \frac{1}{2} b_1 (b_2)^2 c_2 - \frac{1}{2} (a_1)^2 b_1 c_2 - \frac{1}{2} (a_2)^2 c_1 \\
&+ \frac{1}{2} (a_1)^2 b_2 c_1 + \frac{1}{2} a_2 b_1 (c_2)^2 - \frac{1}{2} a_2 (b_1)^2 c_2 - \frac{1}{2} a_2 b_1 (c_2)^2 \\
&- \frac{1}{2} a_1 (b_1)^2 b_2 - \frac{1}{2} (a_2)^2 (c_1)^2 \\
&\neq 0.
\end{align*}$$

(18)

From the very definition it follows that the set of regular bilinear symmetric maps is an open subset $R \subset S^2V^* \otimes V$ in the Zariski topology; precisely, the set where the quartic form $I_3$ does not vanish.

If the ground field $F$ is algebraically closed, then in [2] Theorem 4–2 it is proved that two regular elements $F, G \in R \subset S^2V^* \otimes V$ are $GL(V)$-equivalent, if and only if $I_1(F) = I_2(G)$, $i = 1, 2$, where $I_1, I_2 : R \to F$ are the $GL(V)$-invariant functions defined in [2] Theorem 4-1 and computed in [2] pp. 11–12), namely,

$$I_1(F) = \frac{1}{12 \det Q_{\tilde{F}}} \left[ (a_1 + b_2)^2 ((2b_1 - c_2)^2 + 3(2b_2 - a_1)c_1) \\
+ (a_1 + b_2)(b_1 + c_2)((2b_2 - a_1)(2b_1 - c_2) - 3a_2c_1) \\
+ (b_1 + c_2)^2((2b_2 - a_1)^2 + 3(2b_1 - c_2)a_2) \right],$$

$$I_2(F) = \frac{1}{12 \det Q_{\tilde{F}}} \left[ -c_1(a_1 + b_2)^3 + (a_1 + b_2)^2(b_1 + c_2)(2b_1 - c_2) \\
+ (a_1 + b_2)(b_1 + c_2)^2(2b_2 - a_1) - a_2(b_1 + c_2)^3 \right],$$

where $\det Q_{\tilde{F}}$ is as in (18). Next, we discuss the role of these invariants in the classification problem.

The isomorphism $u : V \to C_0(-q)$, $u(x) = v_1 \cdot x$, $\forall x \in V$, defined in the section [13] induces an isomorphism

$$S^2(u^{*\perp}) \otimes u : S^2(V^*) \otimes V \to S^2(C_0(-q)^*) \otimes C_0(-q)$$

which allows one to transport the invariants $I_1$ and $I_2$ into a Zariski open subset $R'$ in $S^2(C_0(-q)^*) \otimes C_0(-q)$. Moreover, by applying Theorem [12] we can confine ourselves to compute these new invariants $J_1$ and $J_2$ only on the maps $F_{ac}$ fulfilling the equation (10). This is accomplished by using the formulas (8) for $b_0 = b_{12} = 0$, thus obtaining the following expressions:

$$\begin{align*}
J_1(F_{ac}) &= 27K(a, c) + 2N(a)^2 + 3N(a) \\
&= 27K(a, c) + 2N(a)^2 + 3N(a) + 27, \\
J_2(F_{ac}) &= 27K(a, c) + 2N(a)^2 \\
&= 27K(a, c) + 2N(a)^2 + 3N(a) + 27, \\
K(a, c) &= a^3c + \tilde{a}^3\tilde{c}.
\end{align*}$$

(19)
Proposition 6.1. Let $F_{ac}$, $F_{a'c'}$ be two symmetric bilinear maps in Zariski open subset $\mathcal{R}'$ defined above.

If the pairs $(a, c)$ and $(a', c')$ are related by one of the two formulas in the second part of Theorem 12, then $\mathcal{J}_i (F_{ac}) = \mathcal{J}_i (F_{a'c'})$, $i = 1, 2$. Therefore, the functions $\mathcal{J}_1$ and $\mathcal{J}_2$ are invariant under the action of the group of transformations $\mathcal{G}$ given in (12).

Moreover, the equations $\mathcal{J}_i (F_{ac}) = \mathcal{J}_i (F_{a'c'})$, $i = 1, 2$, hold if and only if the following two conditions are fulfilled:

\begin{equation}
(i) \quad N(a') = N(a), \quad (ii) \quad K(a', c') = K(a, c).
\end{equation}

In addition, we have the following mutually excluding cases:

1. If $a = 0$ and (i) and (ii) in (20) hold, then $a' = 0$, and the symmetric bilinear maps $F_{ac}$ and $F_{a'c'}$ are $\mathcal{G}$-equivalent if and only if $\frac{a}{c}$ or $\frac{a'}{c'}$ is a cube in $C_0(-q)$.

2. If $c = 0$, and (i) and (ii) in (20) hold, then $c' = 0$, and the symmetric bilinear maps $F_{ac}$ and $F_{a'c'}$ are equivalent under the subgroup $\mathcal{G}^0 \subset \mathcal{G}$ of the transformations of type (i) in (12).

3. If $a \neq 0$ and $c \neq 0$, then the formulas (i) and (ii) in (20) hold if and only if the symmetric bilinear maps $F_{ac}$ and $F_{a'c'}$ are $\mathcal{G}$-equivalent.

Proof. If $a' = \lambda^{-1}a, c' = \lambda^3c$ or $a' = \lambda^{-1}a, c' = \lambda^3\bar{c}$, then taking account of the fact that $\lambda^{-1} = \bar{\lambda}$ as $\lambda \in \mathcal{G}$, a straightforward computation shows that $\mathcal{J}_i (F_{ac}) = \mathcal{J}_i (F_{a'c'})$, $i = 1, 2$.

Moreover, solving the equations [1] and [2] in (19) with respect to $K(a, c)$ and $N(a)$ it follows

\begin{align*}
K(a, c) &= -2\frac{\mathcal{J}_1(F_{ac})^2 - 2\mathcal{J}_1(F_{ac})^2 - 27\mathcal{J}_1(F_{ac})}{12}\frac{\mathcal{J}_1(F_{ac}) - 8\mathcal{J}_1(F_{ac}) - 27}, \\
N(a) &= -9\frac{\mathcal{J}_1(F_{ac}) - \mathcal{J}_1(F_{ac})}{12\mathcal{J}_1(F_{ac}) - 8\mathcal{J}_1(F_{ac}) - 27}.
\end{align*}

Hence the equations $\mathcal{J}_i (F_{ac}) = \mathcal{J}_i (F_{a'c'})$, $i = 1, 2$, imply $K(a, c) = K(a', c')$ and $N(a) = N(a')$.

(1) From (20)-(i) it follows $N(a') = 0$, and by virtue of (10), we conclude that $N(c) = N(c') = 1$.

If $q$ is elliptic, this implies $a' = 0$, and $c$ and $c'$ are invertible in $C_0(-q)$. If $F_{ac}$ and $F_{a'c'}$ are $\mathcal{G}$-equivalent, then $\frac{a}{c}$ or $\frac{a'}{c'}$ belong to the group $G$ defined in Theorem 12; the converse is obvious.

If $q$ is hyperbolic, we can apply the isomorphism (15); by using the notations introduced therein, the formulas (i) and (ii) in (20) transform respectively into:

\begin{align*}
(i') & a_1'a_2' = 0, \quad (ii') (a_1')^3c_1' + (a_2')^3c_2' = 0, \quad N(c') = 1 \quad \text{means} \quad (iii') c_1'c_2' = 1. \\
\end{align*}

If $a_1' = a_2' = 0$, (i.e., $a' = 0$), then (ii') holds identically and we can conclude as in the previous case. If, for example, we had $a_1' \neq 0, a_2' = 0$, then (ii') implies $(a_1')^3c_1' = 0$, and since $c_1' \in \mathbb{R}^*$ it follows $a_1' = 0$, thus leading us to a contradiction.

(2) From (10) and (20)-(i) it follows $N(a) = N(a') = -1, N(c) = N(c') = 0$.

If $q$ is elliptic, this implies $c = c' = 0$, and $a, a'$ are invertible in $C_0(-q)$ and $\lambda = \frac{a}{a'}$ belongs to $G$. 

10
If $q$ is hyperbolic, then by using the isomorphism (15), the equation (ii) in (20) transforms into (ii') $(a_1')^3c_1' + (a_2')^3c_2' = 0$, and furthermore we have $a_1a_2 = a_1'a_2' = -1$, $c_1'c_2' = 0$. If $c_1' = 0$, then (ii') becomes $(a_2')^3c_2' = 0$, and since $a_2'$ is invertible we deduce that $c_2' = 0$; similarly, $c_2' = 0$ implies $c_1' = 0$. Hence $c' = 0$, in which case we have $\lambda = \frac{a}{a'} \in G$.

(3) If $q$ is elliptic, then $C_0(-q)$ is a field and by virtue of the assumption it follows that the elements $a$, $c$, $\bar{a}$, $\bar{c}$, $a'$, $c'$, $\bar{a}'$, and $\bar{c}'$ are invertible. Letting $a' = \frac{\bar{a}}{\bar{a}'}$, $c' = \frac{\bar{c}}{\bar{c}'}$ into (20)-(ii) we obtain $0 = (\bar{a}^3\bar{c} - \bar{a}^3\bar{c}')(\bar{a}^3c - \bar{a}^3c')$. Hence either $a'^3c = (a')^3c'$ or $a'^3c = (a')^3c'$. In the first case, letting $\lambda = aa^{-1}$, it follows: $a' = \lambda^{-1}a$, $c' = \lambda^3c$, and in the second case, letting $\lambda = \bar{a}a^{-1}$, it follows: $a' = \lambda^{-1}\bar{a}$, $c' = \lambda^3\bar{c}$. As $N(a) = N(a')$, we deduce that $N(\lambda) = 1$, or equivalently $\lambda \in G$.

Therefore, by applying Theorem 4.2 we conclude that the maps $F_{ac}$ and $F_{a'c'}$ are isomorphic.

If $q$ is hyperbolic, then we use the isomorphism (15), and the equations (20)-(i)-(ii) transform respectively into the following:

(i') $a_1a_2 = a_1'a_2'$, (ii') $(a_1')^3c_1' + (a_2')^3c_2' = (a_1)^3c_1 + (a_2)^3c_2$,

and from (10) we also deduce (iii') $c_1c_2 = c_1'c_2'$. The equations (20)-(i)-(ii) being invariant under conjugation, by virtue of the hypothesis we can assume $a_1 \neq 0$, and we distinguish two cases according to whether $c_1 \neq 0$ or $c_1 = 0$ and $c_2 \neq 0$.

1. If $c_1 \neq 0$, then by replacing $a_2 = \frac{a_1}{a_1}a_2'$ and $c_2 = \frac{c_1}{c_1}c_2'$ into (ii') we obtain

$$0 = [(a_1)^3c_1 - (a_1')^3c_1']][(a_1)^3c_1 - (a_2')^3c_2'].$$

- If $(a_1)^3c_1 = (a_1')^3c_1'$, then $a_1' \neq 0$ and $c_1' \neq 0$, and letting $\lambda = (\lambda_1, \lambda_2)$, with $\lambda_1 = \frac{a_1}{a_1'}, \lambda_2 = \frac{1}{\lambda_1}$, we have $a' = \lambda^{-1}a$, $c' = \lambda^3c$, $\lambda \in G$.

- If $(a_1)^3c_1 = (a_2')^3c_2'$, then $a_2' \neq 0$ and $c_2' \neq 0$. Letting $\lambda_1 = \lambda_2 = \frac{a_1}{a_1'}$, we have $a' = \lambda^{-1}a$, $c' = \lambda^3c$, $\lambda \in G$.

2. If $c_1 = 0$, $c_2 \neq 0$, then $N(c) = 0$ and $a_1a_2 = a_1'a_2' = -1$ because of (10), and letting $a_2 = \frac{1}{a_1}$, $a_2' = \frac{1}{a_1'}$ in (ii') we have

$$0 = (a_1)^3c_1' - (a_1')^3(a_1')^3c_1' = (a_1')^3c_1'.

As $N(c') = 0$, either $c_1' = 0$ or $c_1' = 0$. In the first case, the equation (21) transforms into (ii'-a) $(a_1)^3c_2' = (a_1')^3c_2'$, whereas in the second it transforms into (ii'-b) $c_2 = -(a_1)^3(a_1')^3c_1'$.

- If (ii'-a) holds, then $a' = \lambda^{-1}a$, $c' = \lambda^3c$, with $\lambda = (\lambda_1, \lambda_2)$, $\lambda_1 = \frac{a_1}{a_1'}$, $\lambda_2 = \frac{1}{\lambda_1}$.

- If (ii'-b) holds, then $a' = \lambda^{-1}a$, $c' = \lambda^3c$, with $\lambda = (\lambda_1, \lambda_2)$, $\lambda_1 = \frac{a_1}{a_1'}$, $\lambda_2 = \frac{1}{\lambda_1}$.

This proves that $F_{ac}$ and $F_{a'c'}$ are $G$-equivalent in both cases. $\square$
