Abstract: We compute fully differential next-to-leading order QCD cross-sections for Higgs boson production via gluon fusion in the Standard Model. We maintain the full dependence of the cross-sections on the top and bottom quark mass. We find that finite quark mass effects are important given the achieved precision of QCD predictions for gluon fusion. Our Monte-Carlo program HPro can correct existing NNLO fully differential calculations, which employ the approximation of an infinitely heavy top and a vanishing bottom quark Yukawa coupling, for heavy quark finite mass effects through NLO.

Keywords: Higgs, QCD, NLO, NNLO.
1. Introduction

QCD radiative effects in the gluon fusion process for the production of Higgs bosons at hadron colliders have been the subject of detailed theoretical investigations in the last two decades. The next-to-leading order QCD corrections to the inclusive cross-section were computed already in the nineties [1–3]. In these works it was shown that QCD perturbative corrections are substantial.

Exact calculations of perturbative corrections in the gluon fusion process, such as in Ref. [3], are technically involved due to the presence of massive quark loops already at the leading order. With these pioneering NLO computations, the quality of the simplifying approximation of an infinitely heavy top quark and vanishing Yukawa couplings for all other quarks could be assessed.

Such an approximation is indispensable for computing QCD perturbative corrections beyond NLO. Next-to-next-to-leading order QCD corrections for the $gg \rightarrow H$ inclusive cross-section were computed in Refs [4–6]. NNLO corrections, within the same approximation, for fully differential cross-sections were computed in Refs [7–9] and in Refs [10, 11].

The theoretical uncertainty due to scale variations of NNLO inclusive and differential cross-sections is by now remarkably small. While existing tools, such as HIGLU [12] can be used to correct the predictions for the total cross-section for finite quark-mass effects through NLO, fully differential cross-sections for the Higgs boson and its decay products cannot be corrected for the same effects with existing tools. We remedy this situation in our publication.

We have written a parton level Monte-Carlo program HPro which computes fully differential cross-sections at NLO in QCD while keeping the exact dependence on the finite top and bottom quark mass. HPro includes the decays of the Higgs boson to photons and four-lepton final states. It can be used in conjunction with the fully differential NNLO program FEHiP [8,9], correcting for finite quark mass effects through NLO. An earlier version of HPro has been used in [13] to estimate the finite bottom mass effects. Later in a similar study [14] these effects have been also accounted for using HIGLU.

We present the calculation method in Section 2. In Section 3 we use HPro to compute the NLO total cross-section and review the quality of the approximations which are usually made for heavy quark loops in the gluon fusion process. In Section 4, we compute for illustration various kinematic distributions and study the effect of finite quark masses to their shape. We present our conclusions in Section 5.

2. Implementation

The computation of the NLO corrections to the gluon fusion process requires the two-loop $gg \rightarrow h$ amplitude. This has been first computed by means of an one-dimensional integral representation derived in Ref. [3]. In Ref. [15], this result was expressed analytically in terms of harmonic polylogarithms using a “series expansion and matching” method. Independent analytic evaluations of the two-loop amplitude were performed in Ref. [16] and in Ref. [17].
At NLO also real radiation sub-processes $gg \rightarrow gh$, $qg \rightarrow qh$ and $q\bar{q} \rightarrow gh$ contribute. The corresponding matrix elements have been first computed in Ref. [18]. In Ref. [19] these matrix elements have been expressed in terms of standard one-loop scalar integrals and helicity amplitudes. We have recomputed these contributions along the lines of Ref. [19] and found full agreement. In particular we have also compared to a very recent calculation in Ref. [20]. For completeness we present the results in Appendix A.

Virtual and real corrections develop singularities which only cancel in their combination and by adding the appropriate collinear counter-term for PDF evolution. In order to obtain an expression suited for numerical integration we apply the FKS subtraction method [21]. Recently this method has been applied in Ref. [22] for the matching of NLO Higgs production to shower Monte Carlo in the heavy top mass approximation.

We note that in the case of total cross sections the straightforward application of the FKS subtraction method leads to the same analytic formula for the subtraction terms that has been found in Ref. [3]. With appropriate insertion of measurement functions we easily get analytic expressions suited for the calculation of any differential distribution. In practice one might think of the measurement function as a vector valued function with each component being a bin of a certain distribution. There exist implementations of the VEGAS algorithm supporting vector functions, such as the VEGAS routine in the CUBA library [23], which allows to obtain a reliable Monte-Carlo error estimate for each bin. In combination with dedicated decay routines for the diphoton and leptonic final states, this feature enables us to produce various distributions relevant for experimental searches of the Higgs boson, corrected by finite mass effects, as we will demonstrate in the following sections.

3. Total cross-section at NLO

In this section, we revisit the gluon fusion cross-section at NLO. This serves as a check of our Monte-Carlo $\mathbb{HPro}$ against the predictions of $\mathbb{HIGLU}$ [12], and to emphasize the importance of finite quark mass effects in Higgs boson production. For the numerical results of this paper we use MSTW 2008 parton distribution functions [24].

We begin our study by revisiting the total cross-section in the LO and NLO approximation as a function of the Higgs boson mass (Fig. 1). As it is well known [1–3], NLO QCD perturbative corrections are substantial. We note here that the perturbative corrections are slightly smaller with the latest parton densities [24], mainly due to the higher value of $\alpha_s$ used at leading order. We also note that a significant QCD correction is found at NNLO [4–6], which is not included in the results of this article. NNLO corrections stabilize the perturbative expansion and reduce the scale variation to the $\sim 10\%$ level. However, NNLO computations rely on an approximate treatment of heavy quark loops.

In Fig. 1, we show the effects of different treatments for the heavy quarks. With $\mathbb{HPro}$, we compute the exact LO and NLO cross-sections, where all loop diagrams with massive top and bottom quarks are evaluated exactly (we denote with “top+bottom” the corresponding cross-sections in the plots of this paper). An approximation which can be made, is to consider a vanishing bottom Yukawa coupling and to evaluate exactly only the top-quark
loops; in our plots, we denote this approximation as “top-only”. NNLO computations are performed in what is known as the infinitely heavy top-quark approximation. In the “$m_{\text{top}} = \infty$” approximation, the bottom Yukawa coupling is set to zero, and the cross-section at higher orders is estimated by the formula,

$$
\sigma_{(N)\text{NLO}}^{m_{\text{top}} = \infty} = \sigma_{\text{LO}}^{\text{top-only}} \times \lim_{m_{\text{top}} \to \infty} \left( \frac{\sigma_{(N)\text{NLO}}^{\text{top-only}}}{\sigma_{\text{LO}}^{\text{top-only}}} \right),
$$

where bottom quark loops are ignored, and the leading order cross-section is reweighted with the ratio of the cross-sections at higher orders and the leading order in the limit of an infinite top-quark mass. In order to compare the different approximations we introduce

$$
\delta X^i = \frac{X^i - X^{m_{\text{top}} = \infty}}{X^{m_{\text{top}} = \infty}}
$$

where $X$ is the inclusive cross section or a normalized differential cross section and $i$ is labelling the contribution (top+bottom, top-only, etc.)

**Figure 1:** Total Cross-Section at Tevatron and LHC.

**Figure 2:** Percent differences of the exact NLO (LO) total cross-section with finite top bottom masses or the NLO (LO) total cross-section with exact top mass effects but zero bottom Yukawa coupling with respect to the usual approximation at Tevatron and the LHC.
In Fig. 2, we show the cross-section deviations from the $m_{\text{top}} = \infty$ approximation of Eq. 3.1 when “top-only” (blue) and the complete “top-bottom” mass effects are taken into account. “Top-only” contributions are approximated within a couple of a percent up to the $m_H = 2m_{\text{top}}$ threshold. However, for a light Higgs boson, bottom quark contributions are important and can reach $\sim -8\%$. It is then important that bottom loops are taken into account for a precise evaluation of the total cross-section [13]. We also observe that the contribution from bottom-quark loops decreases at NLO in comparison to LO.

In Fig. 3, we show the relative contributions to the NLO total cross-section from top-quark loops only, bottom quark-loops only, and from the interference of top and bottom loops. Top-only contributions are dominant, while bottom-only contributions are negligible over the whole Higgs mass range. Top-bottom interference terms are important at the few percent level and are negative for a light Higgs boson. It should be noted that the relative importance of the three contributions for a heavy Higgs boson or a pseudo-scalar Higgs boson in the MSSM may be drastically different than in the Standard Model [25].

The magnitude of QCD corrections depends strongly on the mass value of the heavy quark in the loops if we use the pole mass for the $q\bar{q}H$ coupling. In Fig. 4 we consider the cross-section for the gluon fusion cross-section at the Tevatron and the LHC, considering only one heavy quark with a mass $m_q$. We find that, in the pole scheme, the K-factor is reduced significantly for small values of the quark mass consistent with neglecting the running of the quark mass in the Higgs coupling at leading order.

For the Standard Model where both top and bottom quark loops contribute to the gluon fusion process, we study separately the magnitude of QCD corrections for the top-only, bottom-only, and top-bottom interference terms. The corresponding K-factors at NLO are plotted in Fig. 5. While the top-only contributions receive a large K-factor, NLO QCD corrections to the top-bottom interference and bottom-only terms are milder. As a consequence, the importance of the bottom-quark loops is smaller at NLO than at LO.

The small NLO QCD corrections to the top-bottom interference contribution, which is also a very small fraction of the top-only contribution, suggests that a more precise evaluation at NNLO is not necessary. The top-only contribution receives however large NLO
Figure 4: NLO cross-section and K-factor for the gluon fusion process via one only heavy quark at the Tevatron and the LHC, as a function of the quark mass.

Figure 5: NLO K-factors for the top-only, bottom-only, and top-bottom interference contributions. We restrict to a range of $m_H$ where top-bottom interference contributions are still sizable.

corrections and it requires an evaluation at NNLO. As shown in Fig. 2, this contribution can be approximated using Eq. 3.1 better than 2% for a light Higgs boson, and better than 10% for a Higgs boson with a mass above the top-pair threshold. It appears to us, that the combination of the NLO cross-section with full dependence on the top and bottom quark masses and the NNLO correction using the approximation of Eq. 3.1 yields a very precise estimate of the gluon fusion cross-section, where differences with an NNLO calculation with exact finite quark mass effects should be quite small.
The results of this section have been extensively cross-checked with HIGLU and excellent agreement has been found.

4. Differential cross-sections at NLO with finite quark masses

The search for a Higgs boson at hadron colliders is complicated due to the large cross-sections of background processes. Sophisticated experimental analyses are required, where it is essential to find optimized selection cuts. In addition, it is often necessary to perform a detailed probabilistic comparison of measured shapes for kinematic distributions with theoretical predictions for the signal and background processes. The role of very accurate Monte-Carlo programs which are fully differential is very important for these purposes.

The fully differential NNLO Monte-Carlo’s, FEHiP [7–9] and HNNLO [10, 11], are available for the gluon fusion Higgs boson production process. Given the complexity of NNLO computations, these programs employ the approximation of Eq. 3.1. In some cases, experimental cuts lead to a significantly smaller scale variation than in the total cross-section. This enhances the importance of other uncertainties, such as the one due to unaccounted finite quark mass effects. A characteristic example is the accepted cross-section for $pp \rightarrow H \rightarrow WW \rightarrow ll\nu\nu$ where a jet-veto and other cuts reduce the uncertainty due to scale variations by a factor of about two with respect to the total cross-section [9, 11, 28].

With our exact NLO Monte-Carlo HPro, we can correct the predictions of FEHiP and HNNLO for finite quark mass effects through NLO. HPro can be used to compute fully differential cross-sections and distributions at NLO for the Higgs boson and the final state particles in the two photon and four lepton decays. HPro is merged with the FEHiP NNLO Monte-Carlo and it will be released in a forthcoming publication. In this section, we illustrate the shapes of a few kinematic distributions with our new HPro NLO Monte-Carlo and compare them with the corresponding predictions in the “$m_{\text{top}} = \infty$” approximation.

![Figure 6: NLO normalized rapidity distribution at the LHC, $m_H = 150$ GeV. Finite quark mass effects affect the shape of the distributions only in the very high rapidity range, where only a tiny fraction of events take place. For $y_H$ values larger than the one marked by the grey line, less than $10^{-3}$ of the total number of events take place.](image-url)

In Figs. 6 and 7, we study the normalized NLO rapidity distribution of a Higgs boson with mass $m_H = 150$ GeV at the LHC and the Tevatron, respectively. Except for very large
Figure 7: NLO normalized rapidity distribution at the Tevatron, $m_H = 150\text{GeV}$. Finite quark mass effects affect the shape of the distributions only in the very high rapidity range, where only a tiny fraction of events take place. For $y^H$ values larger than the one marked by the grey line, less than $10^{-3}$ of the total number of events take place.

rapidities, where almost no events occur, the distribution is not affected by mass effects. Even in that range the deviations from the “$m_{\text{top}} = \infty$” limit are less than 5% at the LHC and less than 10% at the Tevatron. We conclude that small-$x$ effects are moderate and without phenomenological consequences in the case of the rapidity distribution at NLO shedding light on an open question raised in [26, 27].

Another important differential distribution is the transverse momentum of the Higgs boson. Finite quark mass effects for the $p_T$ distribution have also been studied in earlier publications [18, 19, 25], and recently both electroweak and finite quark mass corrections were computed and combined [20].

Figure 8: Normalized $p_T$ distribution at Tevatron, $m_H = 120\text{GeV}$. Massive corrections are important for large $p_T$. However only a very small fraction of events exists in this range.

In Fig. 8 (left panel) we present the normalized cross-section at the Tevatron in $p_T$ bins of 2 GeV, for a Higgs boson with mass $m_H = 120\text{GeV}$. At small values of $p_T$ the bin cross-sections cannot be computed accurately in perturbation theory, see Fig. 9, and an all orders resummation is required [29, 30]. A meaningful result is obtained, however, when the bins at low $p_T$ are added up together. In order to study the effect of finite quark
Figure 9: First few bins of $p_T$ distribution at Tevatron, $m_H = 120$ GeV. The values of these bins are unphysical and require resummation. For phenomenological purposes, these large deviations concern a tiny fraction of potential

masses it is more convenient if we demonstrate uncombined low $p_T$ bins. For this purpose, we present the $p_T$ distribution in the approximation of Eq. 3.1 (cyan), in the “top-only” approximation (blue) where the bottom loops are ignored but the top-loops are evaluated exactly, and with the complete “top-bottom” mass dependence (red). We have compared our results with the authors of [20] and found full agreement within numerical errors. In the right panel of Fig. 8 we show the percent deviations of the complete result (red) and the “top-only” approximation for the normalized $p_T$ distribution from the approximation of Eq. 3.1. At small $p_T$, there are very small differences due to finite quark-mass effects. We observe some important shape deviations due to the effect of top and bottom quark loops at intermediate $p_T$. As it has already been observed in Ref. [20] finite quark effects are very large at high $p_T$, where the quark production channel becomes dominant. Note that additional electroweak corrections affect the shape considerably [20]. At a higher Higgs

Figure 10: Normalized $p_T$ distribution at Tevatron, $m_H = 180$ GeV. Compared to $m_H = 120$ GeV, mass corrections lead to smaller deviations from the “$m_{top} = \infty$” approximation. The spectrum of the bottom-only contribution is much softer (green, left panel). For phenomenological purposes, these large deviations concern a tiny fraction of potential

boson mass value of $m_H = 180$ GeV (Fig. 10) we find an even milder effect at low $p_T$, while the magnitude of the deviations at a large $p_T$ is somewhat reduced but still large.
Higgs signal events for both \( m_H = 120 \text{ GeV} \) and \( m_H = 180 \text{ GeV} \) mass values. We show in Fig. 10 also the “bottom-only” contribution and observe that in this case the \( p_T \) spectrum is much softer, as pointed out in Ref. [25].

![Graphs showing \( p_T \) distributions for different mass values.]

Figure 11: Normalized \( p_T \) distribution at LHC for \( m_H = 120 \text{ GeV} \) and \( m_H = 180 \text{ GeV} \). Mass corrections are much more modest than at Tevatron where the \( q\bar{q} \) channel plays a much bigger rôle.

At LHC energy (14 TeV), Fig. 11, we observe significant bottom-loop effects for a light Higgs boson \( (m_H = 120 \text{ GeV}) \). These are reduced, for a heavier Higgs boson with mass \( m_H = 180 \text{ GeV} \). Shape deviations due to finite quark mass effects can reach up to 10% at high \( p_T \). It is interesting that bottom quark loops for a light Higgs boson change the shape at low \( p_T \). As we explained, the fixed order \( p_T \) spectrum is not physical at low \( p_T \). However, these deviations may also survive after a complete resummation is performed via the matching procedure. It is interesting to examine the \( p_T \) spectrum for a Higgs mass where the heavy top approximation is formally invalid. In Fig. 12 we plot the normalized distribution for \( m_H = 400 \text{ GeV} \) at the LHC. Deviations of the “top-only” contributions from the infinitely heavy top-quark approximation are small for \( p_T < 80 \text{ GeV} \). At higher \( p_T \) the difference increases.

Finally, we present normalized distributions for Higgs decay final state. In Fig. 13 we present the pseudorapidity difference and average \( p_T \) distribution of the two photons in the process \( pp \rightarrow H \rightarrow \gamma\gamma \). Finite quark-mass effects do not affect these distributions. At higher Higgs boson masses the process \( pp \rightarrow H \rightarrow WW \rightarrow ll\nu\nu \) is dominating and we show as an example for this decay mode the \( \phi_{ll} \) distribution in Fig. 14. \( \phi_{ll} \) is the angle in the transverse plane between the two charged leptons in the final state and we find again, that
the shape is very well reproduced by the “m_{top} = \infty” approximation.

In summary, we have found that the shapes of distributions for leptons and photons
from the decay of a Higgs boson are very well approximated by Eq. 3.1. In addition, accepted cross-sections after the application of cuts on jets are affected consistently with the expectations from the shapes of the Higgs $p_T$ spectra.

5. Conclusions

In this paper, we have presented a NLO partonic level Monte-Carlo program HPro, which computes the top and bottom quark mass dependence of differential cross-sections exactly. HPro computes accepted cross-sections after selection cuts and kinematic distributions for final-state particles in the diphoton and four-lepton decay channels.

Finite quark mass effects are important and can affect the precision of NNLO calculations in the infinite top-quark mass approximation. We can use HPro to correct NNLO differential cross-sections for finite quark mass effects. For this purpose, we have interfaced HPro with the fully exclusive NNLO Monte-Carlo FEHiP. The combined program will be released in a forthcoming publication.

A. Real radiation matrix elements

Here we present the results for the matrix elements squared for real radiation processes $gg \rightarrow gh$, $qg \rightarrow qh$ and $q\bar{q} \rightarrow gh$ in terms of helicity amplitudes. We introduce the following shorthand notation for scalar one-loop integrals,

\begin{align}
B(s, m) &= -i(4\pi)^2B_0^\text{fin}(s; m), \\
C(s, m) &= -i(4\pi)^2C_0(0, 0; s; m, m, m) , \\
C_1(s, t, m) &= -i(4\pi)^2C_0(0, s; t; m, m, m), \\
D(s, t, m) &= -i(4\pi)^2D_0(0, 0, 0, m_H^2; s, t; m, m, m, m)
\end{align}

where $B_0$, $C_0$ and $D_0$ are the standard one-loop integrals in the notation of e.g. [31]. $B_0^\text{fin}$ is the finite part of the $B_0$ function, i.e.

$$B_0(s; m) = \frac{i}{(4\pi)^2} \left( \frac{1}{\epsilon} + B_0^\text{fin}(s; m) \right).$$

There exist several publicly available packages for evaluating one-loop integrals [31–33]. However, we used a private implementation and checked against these packages.

In the following we present the real radiation matrix elements squared, averaged over spin and color and divided by the flux factor, in terms of helicity amplitudes, closely adapting the notation in [19]. Note however the different convention regarding helicity
labels. The simplest process is \( q\bar{q} \rightarrow gh \) and the result can be expressed by a single independent helicity amplitude,

\[
\Upsilon_{q\bar{q}}^r(s_{12}, s_{13}, s_{23}) = \frac{\alpha_s^3(N_c^2 - 1)}{16\pi N_c^2 s_{12}} \left( \left| \sum_Q M_{Q}^{q\bar{q}}(s_{12}, s_{13}, s_{23}) \right|^2 + \left| \sum_Q M_{Q}^{q\bar{q}}(s_{12}, s_{23}, s_{13}) \right|^2 \right) .
\]

(A.6)

with

\[
M_{Q}^{q\bar{q}}(s_{12}, s_{13}, s_{23}) = \frac{\Lambda_Q m_Q^2 s_{23}}{s_{23} + s_{13}} \left[ 2(s_{13} + s_{23} - 4m_Q^2)C_1 (m_H^2, s_{12}, m_Q) + \frac{4s_{12}}{s_{23} + s_{13}} (B (s_{12}, m_Q) - B (m_H^2, m_Q)) - 4 \right] .
\]

(A.7)

Here, \( m_Q\Lambda_Q (\Lambda_Q = 1/v) \), is the Higgs-quark-quark coupling and we sum over heavy quarks, \( Q = t, b \).

Similarly simple is the result for \( gg \rightarrow qh \) and \( gq \rightarrow qh \) sub-processes which is obtained by crossing,

\[
\Upsilon_{gg}^r(s_{12}, s_{13}, s_{23}) = \frac{N_c}{N_c^2 - 1} \Upsilon_{q\bar{q}}^r(s_{23}, s_{13}, s_{12}) ,
\]

(A.8)

\[
\Upsilon_{gg}^r(s_{12}, s_{13}, s_{23}) = \frac{N_c}{N_c^2 - 1} \Upsilon_{q\bar{q}}^r(s_{13}, s_{12}, s_{23}) .
\]

(A.9)

More involved is the expression for the \( gg \rightarrow gh \) process. However, it has a compact representation in terms of only two independent helicity amplitudes,

\[
\Upsilon_{gg}^r(s_{12}, s_{13}, s_{23}) = \frac{\alpha_s^3 N_c}{8\pi (N_c^2 - 1)s_{12}^2 s_{13} s_{23}} \left( \left| \sum_Q M_{Q;++-}^{gg}(s_{12}, s_{13}, s_{23}) \right|^2 + \left| \sum_Q M_{Q;++-}^{gg}(s_{13}, s_{12}, s_{23}) \right|^2 + \left| \sum_Q M_{Q;+++}^{gg}(s_{12}, s_{13}, s_{23}) \right|^2 \right) .
\]

(A.10)
The amplitudes appearing in this expression are given by

\[
M_{Q,++}^{gg}(s_{12}, s_{13}, s_{23}) = \Lambda_Q m_Q^2 \left[ -\frac{4s_{12}(s_{12}^2 - s_{13}s_{23})}{(s_{23} + s_{12})(s_{13} + s_{12})} ight. \\
\left. - \frac{1}{2} s_{12}s_{23}(4m_Q^2 s_{13} - s_{12}s_{13}) D(s_{12}, s_{23}, m_Q) \right. \\
\left. - \frac{1}{2} s_{12}s_{13}(4s_{23}m_Q^2 - s_{12}s_{23}) D(s_{13}, s_{12}, m_Q) \right. \\
\left. + \frac{1}{2} s_{23}s_{13}(-s_{12}^2 + 12s_{12}m_Q^2 + 4s_{13}s_{23}) D(s_{13}, s_{23}, m_Q) \right. \\
\left. - \frac{4s_{13}(2s_{12}s_{23} + s_{23}^2)}{(s_{23} + s_{12})^2} B(s_{13}, m_Q) - \frac{4s_{23}(2s_{12}s_{13} + s_{13}^2)}{(s_{13} + s_{12})^2} B(s_{23}, m_Q) \right. \\
\left. - \frac{2s_{13}s_{23}}{(s_{13} + s_{12})^2(s_{23} + s_{12})^2} \left( -4s_{13}^2s_{12} - 2s_{23}s_{13}^2 - 8s_{13}s_{12}s_{23} ight. \\
\left. - 10s_{13}s_{12}^2 - 2s_{23}s_{12}^2 - 10s_{13}s_{23}s_{12} - 4s_{12}s_{23}^2 - 8s_{12}^3 \right) B(m_H^2, m_Q) \right. \\
\left. + \frac{1}{s_{13}s_{23}} C(s_{13}, m_Q) - \frac{2}{s_{12}} s_{13}^2 C(s_{23}, m_Q) \right] \\
\] 

(A.11)

and

\[
M_{Q,++}^{gg}(s_{12}, s_{13}, s_{23}) = \Lambda_Q m_Q^2 \left[ -4(s_{13} + s_{23} + s_{12}) ight. \\
\left. - \frac{1}{2} s_{23}s_{12}(4m_Q^2 s_{13} - s_{13}s_{23} - s_{12}s_{13} - s_{13}^2) D(s_{12}, s_{23}, m_Q) \right. \\
\left. - \frac{1}{2} s_{12}s_{13}(4s_{23}m_Q^2 - s_{12}s_{23} - s_{13}s_{23} - s_{23}^2) D(s_{13}, s_{12}, m_Q) \right. \\
\left. - \frac{1}{2} s_{23}s_{13}(4s_{12}m_Q^2 - s_{12}s_{23} - s_{12}^2 - s_{12}s_{13}) D(s_{13}, s_{23}, m_Q) \right. \\
\left. + \frac{1}{s_{23}s_{13}} (s_{13}s_{12}s_{23} + s_{13}s_{23}^2 + s_{12}s_{23}^2 - 4s_{13}s_{23}m_Q^2)(s_{23} + s_{13}) \right. \\
\left. + \frac{1}{s_{12}s_{23}} (s_{12}s_{13}^2 + s_{12}s_{13}s_{23} - 4s_{12}s_{13}m_Q^2)(s_{23} + s_{12}) \right. \\
\left. + \frac{1}{s_{12}s_{23}} s_{13}^2 - 4s_{12}m_Q^2 s_{13} + s_{13}s_{12}s_{23} + s_{12}s_{13}^2)(s_{13} + s_{12}) \right. \\
\left. C(s_{13}, m_Q) - \frac{2}{s_{12}} s_{12}^2 C(s_{23}, m_Q) \right] \\
\]
