Effect of Salinity and Potassium Enrichment on Some Growth Attributes in Sugar Beet (*Beta vulgaris* L.)

Fadi Abbas¹ and Entessar Al-Jbawi²

1. Homs Agricultural Research Center, General Commission for Scientific Agricultural Research (GCSAR), Damascus, Syria
2. Sugar Beet Research Department, Crops Research Administration, GCSAR, Damascus, Syria

**Abstract:** A pot experiment was conducted during winter growing season of 2014 at Homs Agriculture Research Center, General Commission for Scientific Researches (GCSAR), Syria. A factorial experiment arranged according to complete randomized block design with six replications was used. A combination of four levels of saline irrigation water (tap water, 2,000, 4,000 and 6,000 ppm), with three K levels (180, 360 and 540 ppm), was used to evaluate the effects of saline irrigation water and K enrichment on some growth attributes of two sugar beet varieties (Semper and Alligator). Results showed that all studied growth attributes, i.e., leaf area (LA), leaf number (LN), total dry matter (TDM) and net assimilation rate (NAR) were decreased under salinity stress conditions compared to the control, while K enrichment significantly increased some of the studied characters such as LA, TDM and NAR, but the differences in LN were apparent according to increase in K levels. The variety Semper surpassed significantly the variety Alligator in LA, TDM and NAR. Results also indicated a significant interaction between salinity × potassium enrichment, varieties × potassium enrichment and salinity × varieties.

**Key words:** Salinity, potassium enrichment, growth traits, sugar beet (*Beta vulgaris* L.).

1. Introduction

Sugar beet (*Beta vulgaris* L., family: Chenopodiaceae) is the second largest crop for sugar production in world after sugar cane; it is generally better adapted to less favorable ecological conditions than sugar cane [1]. Sugar beet is considered an important crop in Syrian crop rotation, which is grown in three dates, i.e., autumn (mid. of Oct.), winter (mid. of Feb.) and summer (mid. of Jul.), in both poor and fertile soils. The cultivation area of sugar beet in Syria was 6,000 ha in 2013, with an average yield of 49.5 t/ha [2]. Salinity of soil is a major abiotic stress that has adverse effects on physiological and metabolic processes of plants leading to decreased growth and yield of plants [3, 4].

Accumulation of excessive amounts of soluble salts in soil is a characteristic in arid and sub-arid regions, although not entirely limited to such areas. The ability of plants to tolerate excess salts in the rhizosphere is of considerable importance in arid and semi-arid regions where salinization of soil usually prevails [5]. Members of Chenopodiaceae family including sugar beet, which has halophyte ancestors, can combat salinity by having osmotic regulating mechanisms due to accumulation of Na⁺ and Cl⁻ in their vacuoles and cytoplasm [6, 7]. The tolerance threshold of sugar beet to salinity is high (7 dS/m) [8]. It is salt sensitive during seed germination and seedling emergence, but in the next stages it is salt tolerant and there are variations in sugar beet genotypes [9].

Abbas et al. [10] evaluated the response of 10 sugar beet genotypes irrigated with saline water, the electrical conductivity (ECw) of the water ranged from 8.4 dS/m to 10.4 dS/m during two years and the results revealed a significant variation in the response of the genotypes when irrigated with saline water. Root, top and sugar yields were decreased under saline conditions, but an increase in sugar content and brix occurred under the same conditions. They
concluded the possibility of growing some genotypes, i.e., Kawemira, Waed, Montebaldo, Brigitta and progress successfully if saline water is the major source of irrigation, as in the eastern area of Syria, in summer time (mid. of Jul.).

Abbas and Al-Jbawi [11] showed that there was significant genotype × NaCl × temperature × osmotic potentials interaction on germination percentage, germination speed, radicle length, hypocotyl length and fresh weight, indicating that sugar beet seeds responded differently to salt and temperature changes. Also, Abbas et al. [12] found that the growth attributes such as relative growth rate and net assimilation rate (NAR) of some sugar beet genotypes decreased significantly under salt condition, and the decrease in biomass under saline conditions was correlated with the reduction in leaf area (LA), which resulted in decreases of photosynthetic area.

Sugar beet plants grown under salinity stress showed imbalanced nutrient contents in their tissues. The effect of salt stress on the nutrient concentration in the plant varies among elements. Increasing salt concentration in growth media resulted in reducing K+ uptake by sugar beet plants and in turn, K+ content in shoots [13]. One approach to minimize effects of salinity is use of nutrient foliar application or nutrient enrichment to increase tolerance of plant to salinity by alleviating Na+ and Cl− injury [14]. The beneficial effect of K fertilization on growth, yield and quality of sugar beet was shown by some previous studies. Abdel-Mawly and Zanouny [5] found that total soluble solids, refinable sugar, purity percentages of root juice, total root yield and top yield of sugar beet plants increased as K fertilizer increased. Also, Mehrandish et al. [15] showed that K application increased root yield, shoot yield, impure sugar percent, pure sugar percent and sugar yield.

Abbas et al. [16] performed an experiment on 10 sugar beet genotypes to evaluate their salt tolerance. The results confirmed that Na+ content of the leaves and roots was increased in all of the genotypes subjected to salinity. Such an increase in Na+ was higher in leaves than in roots. On the other hand, K+ content of the leaves and roots was decreased, and was lower in roots than in leaves. Generally, inorganic solutes (Na+ and K+) were found in higher amounts in leaves than in roots. Also, the genotype Kawimera was introduced as the most salt-tolerant and Tigris was pinpointed as the most sensitive one. Due to the importance of the subject, the objective of this study was to evaluate the effects of saline irrigation water and application of K fertilizer on some growth attributes for two sugar beet varieties in pot experiment.

2. Materials and Methods

The experiment was carried out during winter season 2014, at Homs Agricultural Center, General Commission for Scientific Agriculture Researches (GCSAR), Syria. The site has a latitude of 34.7324° N, and longitude of 36.7137° E. A clay loam soil was used in order to assess some growth attributes for two sugar beet (Beta vulgaris L.) varieties (Semper and Alligator) under irrigation with saline water and application of K fertilizer.

Pots of 20 cm diameter and 30 cm in depth were used which were filled with 14 kg of soil. Table 1 shows some properties and texture of the studied soil surface layer 0-30 cm. Pots were arranged in a randomized complete block design (RCBD) including 24 treatments, which were combination of four saline water levels, three K levels and two varieties with six replicates. Three months before planting, P fertilizer was added at a level of 2.5 g/pot, as superphosphate (50% P2O5). N was added at a level of 120 kg N/ha supplied as NH4NO2 (33.5% N), which equals 1.4 g/pot immediately after thinning. Three seeds of each variety were planted on Jan. 16th, 2014. The plants were thinned once after 24 d at a stage of two real leaves appearance.

After thinning, sugar beet plants were subjected to four levels of salt concentrations (NaCl solutions) till
Effect of Salinity and Potassium Enrichment on Some Growth Attributes in Sugar Beet (Beta vulgaris L.)

The following attributes were determined:

The fresh weight of the aerial parts and roots was determined immediately after harvesting. Leaf number (LN) and LA were estimated as follows:

LN: the number of green leaves with a lamina length greater than 6 cm was considered [17].

LA: (cm²/plant) was obtained using the equation proposed by Gohari and Rouhy [18].

\[ \text{LA} = -201.2558 + 12.401L + 13.35W \quad (L > 16 \text{ cm}) \quad (1) \]

\[ \text{LA} = 6.4736 + 0.84138L \cdot W \quad (L < 16 \text{ cm}) \quad (2) \]

where \( L \) and \( W \) are the largest length and width of lamina in centimeters.

Tops and roots were dried for 48 h at 75 °C in a conventional oven (A23B7/03, Procter and Gamble Co., Europe) and weighed. Dry matter partitioning of the tops and roots was determined after drying the whole samples.

NAR (g/m²/day) [19]:

\[ \text{NAR} = \frac{(W_2 - W_1)(\log A_2 - \log A_1)}{(T_2 - T_1)(A_2 - A_1)} \quad (3) \]

where \( W_1, W_2 \) and \( A_1, A_2 \) refer to dry weight to plant and LA at time \( T_1 \) and \( T_2 \) (first and second sampling), respectively.

Statistical analysis: analysis of variance (ANOVA) appropriate for randomized complete block design (RCBD) with three factors was applied [20]. The treatment means were compared using least significant difference (LSD) procedures at 5% level using GeneStat Computer Program v.12.

3. Results

3.1 Effect of Irrigation with Salt Solutions, Foliar Spraying with K, and Varieties on LN, LA, Total Dry Matter (TDM) and NAR

Data presented in Table 1 show that LN, LA, TDM and NAR were significantly decreased by increasing irrigation water salinity levels as compared with the control treatment (tap water). The reduction in LN was noticed at 6,000 ppm level of salinity, while this character was not differed at the other levels.

The studied growth attributes reduced with increasing salt concentration of irrigation water. Such reduction might be due to lowering of the external water potential or the effect of ion toxicity on metabolic processes. At high salt levels, the availability of water becomes so critically low hence growth parameters are inhibited. These results are in agreement with those obtained by Abbas et al. [12], who found that under salinity stress, LA in 10 genotypes decreased by 8.94% as compared to control after 120 d from sowing period. In addition, NAR decreased in all genotypes by an average of 26.47% as compared to control. K enrichment significantly increased some of the studied characters such as LA, TDM and NAR, while the differences in LN were apparent according to increasing K levels, this might be due to the role of K in regulating osmotic potential, and increasing water uptake ability of sugar beet plants [21].

These results are consistent with Monreal et al. [22] who mentioned that K application prevented the depletion of the nutrient in the leaves that may cause reduction in photosynthetic rate and consequently
reduced growth characters. Moreover, K may help in maintaining a normal balance between carbohydrates and proteins and absorbing more K$^+$ cations replaced with Na$^+$, which caused the injury to cell and plant behavior. The differences in the two varieties in LN were clear after 35 d and 50 d, besides TDM and NAR. Data presented in Table 2 show that the variety Semper surpassed significantly Alligator in LA, TDM and NAR. These differences might be due to the genotypic variation existing between those two sugar beet varieties. Under salinity conditions, differences were noticed in varieties behavior. In this respect, Ahmad et al. [23] reported that sugar beet varieties differed significantly for all growth and yield characters.

### Table 2  Effect of salinity, K enrichment levels and sugar beet varieties on leaf number (LN), leaf area (LA), total dry matter (TDM) and net assimilation rate (NAR) after 35 d, 50 d of sowing.

| Salinity level (ppm) | LN (leaf/plant) | LA (cm$^2$/plant) | TDM (g/plant) | NAR (g/m$^2$/day) |
|----------------------|-----------------|-------------------|--------------|------------------|
|                      | 35 d | 50 d | 35 d | 50 d | 35 d | 50 d | 35 d | 50 d |
| 0                    | 6.2  | 12.5 | 241.4 | 647.0 | 4.38 | 12.88 | 10.32 |
| 2,000                | 6.3  | 12.3 | 208.7 | 494.8 | 4.10 | 10.34 | 9.41  |

Significant differences in LN were noticed at 6,000 ppm K$_2$O level only, and there were no differences in the interaction between K levels and the other salinity levels. On the other hand, LA and TDM decreased significantly with increasing salinity level, and increased with increasing K levels. The highest values for LA and TDM after 35 d and 50 d were recorded in the interaction (irrigation with tap water and enrichment with 540 ppm K$_2$O). The lowest values were recorded in the interaction (irrigation with 6,000 ppm and enrichment with 180 ppm K$_2$O).

Similarly, NAR; this character decreased significantly with increasing salinity levels, and increased with increasing K levels. The highest values for NAR were recorded in the interaction (irrigation with tap water and enrichment with 360 ppm and 540 ppm K$_2$O) without any significant differences between these interactions. Also, the lowest values were recorded in the interaction of (irrigation with 6,000 ppm and K enrichment with 180 ppm K$_2$O).
Table 3  Effect of interaction between salinity and K enrichment levels on LN, LA, TDM and NAR after 35 d, 50 d of sowing.

| Salinity level (ppm) | K levels (ppm) | LN (leaf/plant) | LA (cm²/plant) | TDM (g/plant) | NAR (g/m²/day) |
|----------------------|----------------|-----------------|----------------|---------------|----------------|
|                      | 180            | 35 d            | 50 d            | 35 d          | 50 d           |               |

|                      | 540            | 4.67            | 9.17            | 156.4         | 202.7          | 3.08           |
| LSD0.05              |                |                 |                |               |               | 0.595          |
| Probability          |                |                 |                |               |               | 0.145          |

Deinlein et al. [24] stated that K is considered a major osmotically active solute of plant cell, where it enhanced water uptake and root permeability and acted as a guard cell controller, besides its role in increasing water use. So, one approach to minimize the adverse effects of salinity on plant growth is K application to increase salinity tolerance by alleviating Na⁺ and Cl⁻ injury to plants [25]. In this study, K positively affected all the growth attributes and mitigates the negative impact of salinity on growth. These results are consistent with the studies done by Abdel-Mawly and Zanouny [5] and Abbas et al. [12].

3.3 Effect of Interaction between Salinity and Varieties on LN, LA, TDM and NAR

Data presented in Table 4 show the interaction between salinity and varieties on some growth attributes after 35 d and 50 d after emergence, where this interaction was not significant for LN after 35 d but ranged between 6.1 and 6.7. It was noticed that there were no differences between the two varieties, but increasing salinity levels of irrigation reduced LA and TDM. However, Semper variety recorded the highest values for these growth criteria under tap water
Effect of Salinity and Potassium Enrichment on Some Growth Attributes in Sugar Beet (*Beta vulgaris* L.)

### Table 5  Effect of interaction between K enrichment and varieties on LN, LA, TDM and NAR after 35 d, 50 d of sowing.

| K level (ppm) | Varieties | LN (leaf/plant) | LA (cm²/plant) | TDM (g/plant) | NAR (g/m²/day) |
|---------------|-----------|-----------------|----------------|---------------|----------------|
|               |           | 35 d  | 50 d  | 35 d  | 50 d  | 35 d  | 50 d  | 35 d  | 50 d  |
| 180           | Semper    | 5.7   | 11.3  | 189.1 | 398.9 | 3.33  | 7.67  | 7.49  |
|               | Alligator | 5.9   | 11.6  | 177.1 | 377.1 | 3.00  | 7.14  | 7.30  |
| 360           | Semper    | 5.9   | 11.4  | 210.2 | 441.6 | 3.94  | 9.59  | 8.55  |
|               | Alligator | 5.7   | 11.3  | 182.9 | 390.9 | 3.59  | 9.00  | 9.15  |
| 540           | Semper    | 5.8   | 11.7  | 215.4 | 450.3 | 4.37  | 10.40 | 9.17  |
|               | Alligator | 6.1   | 11.3  | 186.1 | 395.5 | 3.79  | 8.99  | 8.96  |
| LSD₀.₀₅      |           | 0.42  | 0.46  | 8.28  | 17.30 | 0.222 | 0.984 | 1.621 |
| Probability  |           | 0.161 | 0.130 | 0.008 | 0.018 | 0.212 | 0.365 | 0.715 |

The highest values for NAR were under tap water irrigation, while the lowest values were recorded with 6,000 ppm irrigation.

### 3.4 Effect of Interaction between K Enrichment and Varieties on LN, LA, TDM and NAR

Data presented in Table 5 show the interaction between K levels and varieties on some growth attributes after 35 d and 50 d after emergence. The differences in LN after 35 d and 50 d were not significant. It ranged between 5.7-6.1 leaf/plant after 35 d, and 11.3-11.7 leaf/plant after 50 d. In each variety, increasing K level increased LA and TDM with superiority to Semper. However, Semper variety recorded the highest values for these growth criteria under 540 ppm K₂O, while the lowest values were recorded in Alligator variety under 180 ppm K₂O. NAR value also increased with increasing K level, but at the same level, differences between the two varieties were not significant.

### 4. Discussion

Results showed that LN was less affected than LA by salinity. It is suggested that most of the reduction in plant LA was caused by the inhibition of leaf expansion. This is consistent with the results of previous studies, which showed that high levels of salinity decreased LA due to the combination of decrease in cell number and cell size [26]. Munns and Termaat [27] demonstrated that for a given amount of NaCl transport to the shoot, reduction in leaf expansion results in the same proportional increase in the leaf NaCl concentration.

The decreased biomass weights of plants under saline conditions are correlated with the reduced LA, which results in decreases of photosynthetic area [28]. It is thought that a decreased photosynthesis under stress could reduce shoot growth and development, leading to lower biomass production compared to control [29], because it is well known that halophytes tolerate saline conditions but with a reduction in growth rate, besides the decrease in dry matter accumulation is mainly due to increase in sodium under high salt stress causing a reduction in the activity of CO₂ fixation during photosynthesis and a decrease in the enzymatic activity of the metabolic processes. Different cultivars of the same plant had different behavior toward salt tolerance [30, 31]. The obtained results indicated that NAR of the two genotypes decreased significantly under salt condition, this might be due to the osmotic inhibition of water absorption, accumulation of certain ions in high concentration in plant tissues and alteration of the mineral balance of plants, and/or due to the reduction...
in photosynthetic activity and carbohydrates metabolism.

The positive effect of K on growth may be due to the prevalent K action in plants and its role in maintenance of the ionic balance in cell, and bounds ionically to enzyme pyruvate kinase which is essential in respiration and carbohydrate metabolism [32]. However, the salt tolerance in plants increased by increasing K uptake which leads to increasing K/Na ratio in plant cells. Moreover, K plays an important role in regulating osmotic potential, increasing water uptake ability of sugar beet plants [21]. They added that, foliar application with K could be used to avoid the depletion of this nutrient in the leaves that may cause reduction in photosynthetic rate and consequently reduce growth characters. Moreover, it is involved in activating a wide range of enzyme systems.

5. Conclusions

The foregoing discussion showed that all studied growth attributes LA, LN, TDM and NAR were decreased under salinity stress conditions compared to the control, and K enrichment significantly increased some of the studied characters such as LA, TDM and NAR, while the differences in LN were apparent according to increasing K levels. Also, the results confirm that the genotypes differed significantly in all studied attributes except in LN and NAR under salt conditions.

The results of the study recommended further studies to correlate the yield with yield components under similar conditions to determine the most tolerant genotype.
