**Diffusion tensor regularization with metric double integrals**

https://doi.org/10.1515/jiip-2021-0041
Received June 28, 2021; accepted October 22, 2021

**Abstract:** In this paper, we propose a variational regularization method for denoising and inpainting of diffusion tensor magnetic resonance images. We consider these images as manifold-valued Sobolev functions, i.e. in an infinite dimensional setting, which are defined appropriately. The regularization functionals are defined as double integrals, which are equivalent to Sobolev semi-norms in the Euclidean setting. We extend the analysis of [14] concerning stability and convergence of the variational regularization methods by a uniqueness result, apply them to diffusion tensor processing, and validate our model in numerical examples with synthetic and real data.

**Keywords:** Regularization, diffusion tensor, metric double integrals

**MSC 2010:** 47A52, 65J20

**1 Introduction**

In this paper, we investigate denoising and inpainting of diffusion tensor (magnetic resonance) images (DTMRI) with a derivative-free, non-local variational regularization technique proposed, implemented and analyzed first in [14].

The proposed regularization functionals generalize equivalent definitions of the Sobolev semi-norms, which have been derived in the fundamental work of [11] and follow-up work [16, 40]. These papers provide a derivative-free representation of Sobolev semi-norms for intensity and vector-valued functions. The beauty of this representation is that it allows for a straightforward definition of Sobolev energies of manifold-valued data (see [14]), without requiring difficult differential geometric concepts (as for instance in [15, 21]).

Diffusion tensor images are considered to be re-presentable as functions from an image domain $\Omega \subset \mathbb{R}^n$, with $n = 2, 3$, respectively, into the manifold of symmetric, positive definite matrices in $\mathbb{R}^{m \times m}$, denoted by $K$ in the following – for DTMRI images $m = 3$. Therefore, they are ideal objects to check the efficiency of the proposed regularization techniques. A measured diffusion tensor is often very noisy, and post-processing steps for noise removal are important. Even more, due to the noise, it is possible that a measured tensor has negative eigenvalues, which is not physical, and thus often the whole tensor at this point is omitted, leading to incomplete data. Then the missing information has to be inpainted before visualization.

Variational regularization of vector and matrix manifold-valued functions has been considered before, for instance in [5, 8, 30, 36, 44, 46, 49, 50] and [9, 12, 34, 37]. Non-local regularization formulations were studied for example in [10, 28] for filtering tensor-valued functions, and also [22, 29] for filtering intensity images. An overview of diffusion and regularization techniques for vector- and matrix-valued data is given in [49].

Variational methods for denoising and inpainting attempt to find a good compromise between matching some given noisy, tensor-valued data \( w^\delta : \Omega \to K \) and prior information on the desired solution \( w^0 : \Omega \to K \), also called noise-free or ideal solution. The choice of prior knowledge on \( w^0 \) is

- (i) that it is an element of the set \( W^{s,p}(\Omega; K) \), with a metric \( d \) on \( K \), the set of positive definite matrices, which is a subset of the fractional Sobolev space \( W^{s,p}(\Omega; \mathbb{R}^{m \times m}) \), with \( s \in (0, 1) \) and \( p \in (1, \infty) \),
- (ii) and that

\[
\Phi^l_{d}(w) := \iint_{\Omega \times \Omega} \frac{d^p(w(x), w(y))}{|x-y|^{mp+s}} \rho^l(x-y) \, d(x,y)
\]  

is relatively small. The function \( \rho \) is a non-negative and radially symmetric mollifier with an on-off indicator \( l \in \{0, 1\} \) denoting whether the mollifier is used or not. Note that, in case that \( d = d_{\mathbb{R}^{m \times m}} \) is the Euclidean metric and if we choose in addition \( l = 0 \), then \( \Phi^0_{d_{\mathbb{R}^{m \times m}}} \) becomes the fractional Sobolev semi-norm.

The compromise of approximating \( w^\delta \) with a function in \( W^{s,p}(\Omega; K) \) with a small energy term \( \Phi^l_{d}(w) \) is achieved by minimization of the functional

\[
\mathcal{J}^{\alpha, w^\delta}_{d}(w) := \iint_{\Omega \setminus D} \chi_{\Omega \setminus D}(x) d^p(w(x), w^\delta(x)) \, dx + \alpha \Phi^l_{d}(w),
\]  

where the parameter \( \alpha > 0 \) determines the preference of staying close to the given function \( w^\delta \) in \( \Omega \setminus D \) and a small energy \( \Phi^l_{d}(w) \). One should not confuse the energy term with double integral representations approximating semi-norms on manifolds (see for instance [19, 24, 27]).

The indicator function of \( \Omega \setminus D \),

\[
\chi_{\Omega \setminus D}(x) = \begin{cases} 
1 & \text{if } x \in \Omega \setminus D, \\
0 & \text{otherwise},
\end{cases}
\]

used in (1.2) allows us to consider the two tasks of denoising \((D = \emptyset)\) and inpainting \((D \neq \emptyset)\) within one analysis.

The paper is organized as follows. In Section 2, we constitute our notation and setting used to analyze variational methods for DTMRI data processing. We review regularization results from [14] in Section 3. In Section 4, we verify that these results from Section 3 are applicable in the context of diffusion tensor imaging, meaning that we show that the functional \( \mathcal{J}^{\alpha, w^\delta}_{d} \) defined in (1.2) attains a minimizer and fulfills a stability as well as a convergence result. Furthermore, we extend the analysis and give a uniqueness result using differential geometric properties of symmetric, positive definite matrices, where it is of particular importance that these matrices endowed with the log-Euclidean metric form a flat Hadamard manifold. In Section 5, we give more details on the numerical minimization of the regularized functional, and discuss different variants. In the last section, Section 6, we show numerical results for denoising and inpainting problems of synthetic and real DTMRI data.

## 2 Notation and setting

In the beginning, we summarize basic notation and assumptions used throughout the paper. In the theoretical part, we work with general dimensions \( n, m \in \mathbb{N} \), while we consider the particular case \( n = 2, m = 3 \), that is two-dimensional slices of a three-dimensional DTMRI image, in the numerical examples in Section 6.
Assumption 2.1. We assume the following.

(i) $\Omega \subset \mathbb{R}^n$ is a nonempty, bounded and connected open set with Lipschitz boundary, and $D \subset \Omega$ is measurable.

(ii) $p \in (1, \infty), s \in (0, 1)$ and $l \in \{0, 1\}$.

(iii) $K \subseteq \mathbb{R}^{m \times m}$ is a nonempty and closed subset of $\mathbb{R}^{m \times m}$.

(iv) $d_{\mathbb{R}^{m \times m}} : \mathbb{R}^{m \times m} \times \mathbb{R}^{m \times m} \to [0, \infty)$ denotes the Euclidean distance induced by the (Frobenius norm) on $\mathbb{R}^{m \times m}$.

(v) $d := d_K : K \times K \to [0, \infty)$ denotes an arbitrary metric on $K$ which is equivalent to $d_{\mathbb{R}^{m \times m}}$.

Moreover, we need the definition of a mollifier which appears in the regularizer of the functional in (1.2).

Definition 2.2 (Mollifier). We call $\rho \in C^\infty_c (\mathbb{R}^n; \mathbb{R})$ a mollifier if

- $\rho$ is a non-negative, radially symmetric function,
- $\int_{\mathbb{R}^n} \rho(x) \, dx = 1$ and
- there exists some $0 < \tau < \| \rho \|_{L^\infty(\mathbb{R}^n; \mathbb{R})}$ and $\eta := \eta_\tau > 0$ such that $\{ z \in \mathbb{R}^n : \rho(z) \geq \tau \} = \{ z \in \mathbb{R}^n : |z| \leq \eta \}$.

The last condition holds for instance if $\rho$ is radially decreasing satisfying $\rho(0) > 0$.

2.1 Diffusion tensors

It is commonly assumed that the recorded diffusion tensor images are functions with values which are symmetric, positive definite matrices. Hence we make the assumption that

$$w, w^\delta : \Omega \to \text{SPD}(m),$$

where $\text{SPD}(m)$ is the set of symmetric, positive definite, real $m \times m$ matrices defined below in (2.1). When working with data from MRI measurements, $m = 3$.

In the following definition, we summarize sets of matrices and associated norms on the sets.

Definition 2.3. The vector space of symmetric matrices is

$$\text{SYM}(m) := \{ M \in \mathbb{R}^{m \times m} : M^T = M \}.$$  

Additionally, we define the set of symmetric, positive definite $m \times m$ matrices

$$\text{SPD}(m) := \{ M \in \text{SYM}(m) : x^T M x > 0 \text{ for } x \in \mathbb{R}^m \setminus \{0\} \}. \tag{2.1}$$

The set of symmetric, positive definite matrices with bounded spectrum is

$$\text{SPD}^{\text{spec}}_{[\varepsilon, \overline{\varepsilon}]} (m) := \{ M \in \text{SPD}(m) : \text{spec}(M) \subseteq [\varepsilon, \overline{\varepsilon}] \}, \tag{2.2}$$

where spec denotes the spectrum of a given matrix. For diffusion tensors, the spectrum is real.

The set of symmetric, positive definite matrices with bounded logarithm is

$$\text{SPD}^{\text{log}}_{z}(m) := \{ M \in \text{SPD}(m) : \| \text{Log}(M) \|_F \leq z \}, \tag{2.3}$$

where $\text{Log}$ is the matrix logarithm defined later in Definition 4.2 (ii) and $\| \cdot \|_F$ denotes the Frobenius norm defined as

$$\| M \|_F = \sqrt{\sum_{i,j=1}^{m} |m_{ij}|^2}. \tag{2.4}$$

When working with DT-MRI data, in particular in Section 6, we will chose $K = \text{SPD}^{\text{log}}_{3}(3)$. In the general theory stated in Section 3, any nonempty and bounded set can be taken.

From now on and whenever possible, we omit the space dimension and write $\text{SYM}(m), \text{SPD}(m), \text{SPD}^{\text{spec}}_{[\varepsilon, \overline{\varepsilon}]} (m)$ and $\text{SPD}^{\text{log}}_{z}(m)$ instead of $\text{SYM}(m), \text{SPD}(m), \text{SPD}^{\text{spec}}_{[\varepsilon, \overline{\varepsilon}]} (m)$ and $\text{SPD}^{\text{log}}_{z}(m)$. 

2.2 Fractional Sobolev spaces

Moreover, we need the definition of fractional Sobolev spaces and associated subsets.

**Definition 2.4 (Sobolev spaces of fractional order).** Let Assumption 2.1 hold.

- We denote by \( L^p(\Omega; \mathbb{R}^{m \times m}) \) the Lebesgue space of matrix-valued functions.
- The Sobolev space \( W^{1,p}(\Omega; \mathbb{R}^{m \times m}) \) consists of all weakly differentiable functions in \( L^p(\Omega; \mathbb{R}^{m \times m}) \) for which
  \[
  \|w\|_{W^{1,p}(\Omega; \mathbb{R}^{m \times m})} := \left( \|w\|_{L^p(\Omega; \mathbb{R}^{m \times m})}^p + \int_{\Omega} |\nabla w(x)|^p \, dx \right)^{1/p} < \infty,
  \]
  where \( \nabla w \) is the Jacobian of \( w \) and \( |w|_{W^{1,p}(\Omega; \mathbb{R}^{m \times m})} := \left( \int_{\Omega} |\nabla w(x)|^p \, dx \right)^{1/p} \) is the Sobolev semi-norm.

- The fractional Sobolev space of order \( s \) is defined (cf. [1]) as the set
  \[
  W^{s,p}(\Omega; \mathbb{R}^{m \times m}) := \left\{ w \in L^p(\Omega; \mathbb{R}^{m \times m}) : \frac{|w(x) - w(y)|_F}{|x - y|^{n + sp}} \in L^p(\Omega \times \Omega; \mathbb{R}) \right\}
  \]
  equipped with the norm
  \[
  \|w\|_{W^{s,p}(\Omega; \mathbb{R}^{m \times m})} := \left( \|w\|_{L^p(\Omega; \mathbb{R}^{m \times m})}^p + |w|_{W^{s,p}(\Omega; \mathbb{R}^{m \times m})}^p \right)^{1/p},
  \]
  where \( |w|_{W^{s,p}(\Omega; \mathbb{R}^{m \times m})} \) is the semi-norm on \( W^{s,p}(\Omega; \mathbb{R}^{m \times m}) \), defined by
  \[
  |w|_{W^{s,p}(\Omega; \mathbb{R}^{m \times m})} := \left( \int_{\Omega \times \Omega} \frac{|w(x) - w(y)|_F^p}{|x - y|^{n + ps}} \, d(x, y) \right)^{1/p} \quad \text{for all } w \in W^{s,p}(\Omega; \mathbb{R}^{m \times m}).
  \]

- We define the fractional Sobolev set of order \( s \) with data in \( K \) as
  \[
  W^{s,p}(\Omega; K) := \{ w \in W^{s,p}(\Omega; \mathbb{R}^{m \times m}) : w(x) \in K \text{ for a.e. } x \in \Omega \}.
  \]

The Lebesgue set with data in \( K \) is defined as
\[
L^p(\Omega; K) := \{ w \in L^p(\Omega; \mathbb{R}^{m \times m}) : w(x) \in K \text{ for a.e. } x \in \Omega \}.
\]
Note that \( L^p(\Omega; K) \) and \( W^{s,p}(\Omega; K) \) are sets and not linear spaces because summation of elements in \( K \) is typically not closed in \( K \).

3 Metric double integral regularization on closed subsets

We start this section by stating conditions under which the regularization functional in (1.2) attains a minimizer and fulfills a stability as well as a convergence result. Therefore, we recall results established in [14].

There the authors define a regularization functional inspired by the work of Bourgain, Brézis and Mironescu [11, 16, 40]. The analysis in turn is based on [41]. We apply these results to diffusion tensor image denoising and inpainting in the next section.

We start by stating general conditions on the exact data \( w^0 \), the noisy data \( w^\delta \) and the functional \( \mathcal{J}_{\mathbb{R}^{m \times m}}^{t, \delta} \), defined in (1.2).

**Assumption 3.1.** Let Assumption 2.1 hold. Moreover, let \( w^0, w^\delta \in L^p(\Omega; K) \), and let \( \rho \) be a mollifier as defined in Definition 2.2. We assume that

(i) for every \( t > 0 \) and \( \alpha > 0 \), the level sets

\[
\text{level}(\mathcal{J}_{\mathbb{R}^{m \times m}}^{t, \delta}; t) := \{ w \in W^{s,p}(\Omega; K) : \mathcal{J}_{\mathbb{R}^{m \times m}}^{t, \delta}(w) \leq t \}
\]

are weakly sequentially pre-compact in \( W^{s,p}(\Omega; \mathbb{R}^{m \times m}) \).

(ii) There exists \( \ell > 0 \) such that \( \text{level}(\mathcal{J}_{\mathbb{R}^{m \times m}}^{\ell, \delta}; \ell) \) is nonempty.
Remark 3.2. If Assumption 2.1 is fulfilled and in particular when performing image denoising (\(D = 0\)) or inpainting (\(D \neq 0\)) of functions with values in \(K\), then the functional (1.2) with \(\Phi^f_{[d]}\) as in (1.1) defined on \(W^{s,p}(\Omega; K)\) satisfies Assumption 3.1 (cf. [14]).

According to [14], we now have the following result giving existence of a minimizer of the functional in (1.2) as well as a stability and convergence result.

**Theorem 3.3.** Let Assumption 3.1 hold (which is guaranteed by Remark 3.2). For the functional defined in (1.2) over \(W^{s,p}(\Omega; K)\) with \(\Phi^f_{[d]}\) defined in (1.1), the following results hold.

- **Existence:** For every \(v \in L^p(\Omega; K)\) and \(\alpha > 0\), the functional \(\mathcal{F}^{\alpha,f}_{[d]} : W^{s,p}(\Omega; K) \to [0, \infty)\) attains a minimizer in \(W^{s,p}(\Omega; K)\).
- **Stability:** Let \(\alpha > 0\) be fixed, \(w^\delta \in L^p(\Omega; K)\), and let \((v_k)_{k \in \mathbb{N}}\) be a sequence in \(L^p(\Omega; K)\) such that
  \[
  \|w^\delta - v_k\|_{L^p(\Omega; K)} \to 0.
  \]
  Then every sequence \((w_k)_{k \in \mathbb{N}}\) satisfying
  \[
  w_k = \arg\min \{ \mathcal{F}^{\alpha,f}_{[d]}(w) : w \in W^{s,p}(\Omega; K) \}
  \]
  has a converging subsequence with respect to the weak topology of \(W^{s,p}(\Omega; \mathbb{R}^{m \times m})\). The limit \(\tilde{w}\) of every such converging subsequence \((w_k)_{k \in \mathbb{N}}\) is a minimizer of \(\mathcal{F}^{\alpha,f}_{[d]}\). Moreover, \((\Phi^f_{[d]}(w_k))_{k \in \mathbb{N}}\) converges to \(\Phi^f_{[d]}(\tilde{w})\).
- **Convergence:** Let \(\alpha : (0, \infty) \to (0, \infty)\) be a function satisfying \(\alpha(\delta) \to 0\) and \(\frac{\delta p}{\alpha(\delta)} \to 0\) for \(\delta \to 0\). Let \((\delta_k)_{k \in \mathbb{N}}\) be a sequence of positive real numbers converging to 0. Moreover, let \((v_k)_{k \in \mathbb{N}}\) be a sequence in \(L^p(\Omega; K)\) with \(\|w^0 - v_k\|_{L^p(\Omega; K)} \leq \delta_k\), and set \(\alpha_k := \alpha(\delta_k)\). Then every sequence \((w_k)_{k \in \mathbb{N}}\) defined as
  \[
  w_k = \arg\min \{ \mathcal{F}^{\alpha,f}_{[d]}(w) : w \in W^{s,p}(\Omega; K) \}
  \]
  has a weakly converging subsequence \(w_{k_j} \to w^0\) as \(j \to \infty\) (with respect to the topology of \(W^{s,p}(\Omega; \mathbb{R}^{m \times m})\)). In addition, \(\Phi^f_{[d]}(w_k) \to \Phi^f_{[d]}(w^0)\). Moreover, it follows that even \(w_k \to w^0\) weakly (with respect to the topology of \(W^{s,p}(\Omega; \mathbb{R}^{m \times m})\) and \(\Phi^f_{[d]}(w_k) \to \Phi^f_{[d]}(w^0)\).

In the theorem above, stability (with respect to the \(L^p\)-norm) ensures that the minimizers of \(\mathcal{F}^{\alpha,f}_{[d]}\) depend continuously on the given data \(w^\delta\). We emphasize that, in an Euclidean setting (that is on \(W^{s,p}(\Omega; \mathbb{R}^{m \times m})\), for \(s > 0\) and \(p > 1\), one could expect convergence in even stronger norms. However, here, we have to make sure that the traces into \(K \subseteq \mathbb{R}^{m \times m}\) are well-defined in appropriate Sobolev spaces, which requires additional compactness assumptions, or in other words, stronger regularization.

In the next section, we apply Theorem 3.3 to diffusion tensor images, i.e. when choosing \(K\) as a closed subset of the symmetric, positive definite matrices.

### 4 Diffusion tensor regularization

The goal of this section is to define appropriate fractional order Sobolev sets as defined in (2.5) of functions which can represent diffusion tensor images. To this end, we use the set of symmetric, positive definite \(m \times m\) matrices with bounded logarithm (defined in (2.3))

\[
K = \text{SPD}_d^{\text{log}}
\]

and associate it with the log-Euclidean metric, defined below in (4.6). This metric was shown to be an adequate distance measure for DTMRI, see e.g. [2, 20].

Below, we show that Theorem 3.3 applies to the regularization functional in (1.2) with the particular choice \(K = \text{SPD}_d^{\text{log}}\). In addition to what follows from the general theory from [14] in a straightforward manner, we present a uniqueness result for the minimizer of the regularization functional.

We begin by defining needed concepts from matrix calculus. When working with symmetric, positive definite matrices, many of the operations below reduce to their scalar counterpart applied to the eigenvalues.
4.1 Matrix calculus

We start this section by repeating basic definitions known from matrix calculus (see for instance [35]). Especially the matrix logarithm is needed to define the log-Euclidean metric on the symmetric, positive definite matrices.

**Lemma 4.1** (Matrix properties). The following statements hold.
(i) Eigendecomposition: Let $A \in \text{SYM}$ with eigenvalues $(\lambda_i)_{i=1}^m$. Then we can write

$$A = U \Lambda U^T,$$

where $U \in \mathbb{R}^{m \times m}$ is the orthonormal matrix whose $i$-th column consists of the $i$-th normalized eigenvector of $A$. Hence we have that $UU^T = I_m$, where $I_m$ denotes the identity matrix in $\mathbb{R}^{m \times m}$. Further, $\Lambda$ is the diagonal matrix whose diagonal entries are the corresponding eigenvalues, $\Lambda = \text{diag}(\lambda_1, \ldots, \lambda_m)$.

(ii) If $U, V \in \mathbb{R}^{m \times m}$ are both unitary, then so are $U^T, U, VU^T$ and $V^T U$.

Next we state the definitions of the matrix exponential and logarithm, see in particular [3, 38].

**Definition 4.2.** Let $A, B \in \text{SYM}$ with corresponding eigendecompositions $A = U \Lambda_A U^T$ and $B = V \Lambda_B V^T$, where $U, V \in \mathbb{R}^{m \times m}$ unitary and $\Lambda_A = \text{diag}(\lambda_1, \ldots, \lambda_m)$, $\Lambda_B = \text{diag}(\mu_1, \ldots, \mu_m) \in \mathbb{R}^{m \times m}$ diagonal.

(i) **Exponential map:** The exponential map is defined as

$$\text{Exp}(A) = \text{Exp}(U \Lambda_A U^T) = U \text{Exp}(\Lambda_A) U^T.$$

It holds that

$$\text{Exp}(\Lambda_A) = \text{diag}(e^{\lambda_1}, \ldots, e^{\lambda_m}),$$

where $e : \mathbb{R} \to \mathbb{R}_{>0}$ denotes the (scalar) exponential function, and $\text{Exp} : \text{SYM} \to \text{SPD}$ is a diffeomorphism [3, Theorem 2.8].

(ii) **Logarithm:** If $\text{Exp}(A) = B$, then $A$ is the matrix logarithm of $B$. It is defined as

$$\text{Log}(B) = \text{Log}(V \Lambda_B V^T) = V \text{Log}(\Lambda_B) V^T.$$

Moreover,

$$\text{Log}(\Lambda_B) = \text{diag}(\log(\mu_1), \ldots, \log(\mu_m)),$$

where $\log : \mathbb{R}_{>0} \to \mathbb{R}$ is the (scalar) natural logarithm, i.e. $\log := \log_e$.

When restricting to symmetric, positive definite matrices, $\text{Log} : \text{SPD} \to \text{SYM}$ is a diffeomorphism [3, Theorem 2.8].

The previous definition, Definition 4.2, shows that the exponential and logarithm of a symmetric (positive definite) matrix can be computed easily due to the eigendecomposition (see Remark 4.1) by calculating the scalar exponential map and logarithm of the eigenvalues.

**Remark 4.3** (Matrix logarithm). For a general matrix in $\mathbb{R}^{m \times m}$, the matrix logarithm is not unique. Matrices with positive eigenvalues have a unique, symmetric logarithm, called the principal logarithm [3].

The next lemma states properties of the Frobenius norm (recall (2.4)).

**Lemma 4.4** (Properties of Frobenius norm). We have the following properties.

(i) Let $A, B \in \mathbb{R}^{m \times m}$ be symmetric and skew-symmetric, respectively, i.e. $A = A^T$, $B = -B^T$. Then

$$\|A + B\|_F^2 = \|A\|_F^2 + \|B\|_F^2. \quad (4.2)$$

(ii) The Frobenius norm is unitary invariant, i.e.

$$\|A\|_F = \|UAV\|_F \quad (4.3)$$

for $A \in \mathbb{R}^{m \times m}$ and $U, V \in \mathbb{R}^{m \times m}$ unitary.
(iii) If $A \in \text{SPD}$ with (positive) eigenvalues $(\lambda_i)_{i=1}^m$, then

$$\| \log(A) \|_F = \left( \sum_{i=1}^m \log^2(\lambda_i) \right)^{1/2}.$$  

(4.4)

Proof. The proof of the first item is straightforward by using the definition of $\| \cdot \|_F$ in (2.4). The second item follows directly by considering the trace representation of the Frobenius norm [51]:

$$\| UAV \|_F^2 = \text{trace}((UAV)^T UAV) = \text{trace}(V^T A^T AV) = \text{trace}(AVV^T A^T) = \| A \|_F^2.$$  

The third item is a direct consequence of Remark 4.1 (i), Definition 4.2 (ii) and (4.3). □

The last lemma of this subsection deals with the set $\text{SPD}^{\text{spec}}_{[\varepsilon, \overline{\varepsilon}]}$, the set of symmetric, positive definite matrices with bounded spectrum in the interval $[\varepsilon, \overline{\varepsilon}]$, defined in (2.2). We need this result later in the numerical implementation for defining a suitable projection. Given an arbitrary matrix $A \in \mathbb{R}^{m \times m}$, there always exists a unique matrix $M \in \text{SPD}^{\text{spec}}_{[\varepsilon, \overline{\varepsilon}]}$ which is closest in the Frobenius norm, i.e.

$$M = \arg \min_{X \in \text{SPD}^{\text{spec}}_{[\varepsilon, \overline{\varepsilon}]} \setminus \{I\}} \| A - X \|_F^2.$$  

The minimizing matrix $M$ can be computed explicitly as stated in the following lemma. The proof is done in a way similar to [25, Theorem 2.1] and is included here for completeness.

Lemma 4.5. Let $A \in \mathbb{R}^{m \times m}$. Define $B := \frac{1}{2}(A + A^T)$ and $C := \frac{1}{2}(A - A^T)$ as the symmetric and skew-symmetric parts of $A$, respectively. Let $(\lambda_i)_{i=1}^m$ be the eigenvalues of $B$ which can be decomposed into $B = Z \Lambda Z^T$, where $Z$ is a unitary matrix, i.e. $ZZ^T = Z^T Z = \mathbb{I}_m$, and $\Lambda = \text{diag}(\lambda_1, \ldots, \lambda_m)$. Then the unique minimizer of

$$\min_{X \in \text{SPD}^{\text{spec}}_{[\varepsilon, \overline{\varepsilon}]} \setminus \{I\}} \| A - X \|_F^2,$$  

where $\text{SPD}^{\text{spec}}_{[\varepsilon, \overline{\varepsilon}]}$ is defined in (2.2), is $Z \Lambda Z^T$ with $Y = \text{diag}(d_1, \ldots, d_m)$, where

$$d_i := \begin{cases} \lambda_i & \text{if } \lambda_i \in [\varepsilon, \overline{\varepsilon}], \\ \overline{\varepsilon} & \text{if } \lambda_i > \overline{\varepsilon}, \\ \varepsilon & \text{if } \lambda_i < \varepsilon. \end{cases}$$

Proof. By definition of $B$ and $C$, we can write $A = B + C$ and thus

$$\| A - X \|_F^2 = \| B + C - X \|_F^2 = \| B - X \|_F^2 + \| C \|_F^2,$$  

where we used (4.2) in the second equality. The problem in (4.5) thus reduces to finding

$$\arg \min_{X \in \text{SPD}^{\text{spec}}_{[\varepsilon, \overline{\varepsilon]} \setminus \{I\}}} \| B - X \|_F^2.$$  

The matrix $B$ is symmetric, and thus we can write $B = Z \Lambda Z^T$, where $Z \in \mathbb{R}^{m \times m}$ is a unitary matrix whose columns are the eigenvectors of $B$ and $\Lambda \in \mathbb{R}^{m \times m}$ is a diagonal matrix whose entries are the eigenvalues of $B$, i.e. $\Lambda = \text{diag}(\lambda_1, \ldots, \lambda_m)$. Let $Y = Z^T X Z$ be similar to $X$ so that $\text{spec}(Y) \subset [\varepsilon, \overline{\varepsilon}]$. Then we obtain, by using (4.3),

$$\| B - X \|_F^2 = \| \Lambda - Y \|_F^2 = \sum_{(i,j) \in \bar{I}} y_{ij}^2 + \sum_{i=1}^m (\lambda_i - y_{ii})^2$$

$$= \sum_{(i,j) \in \bar{I}} y_{ij}^2 + \sum_{i : \lambda_i \in [\varepsilon, \overline{\varepsilon}]} (\lambda_i - y_{ii})^2 + \sum_{i : \lambda_i > \overline{\varepsilon}} (\lambda_i - y_{ii})^2 + \sum_{i : \lambda_i < \varepsilon} (\lambda_i - y_{ii})^2$$

$$\geq \sum_{i : \lambda_i > \overline{\varepsilon}} (\lambda_i - \overline{\varepsilon})^2 + \sum_{i : \lambda_i < \varepsilon} (\lambda_i - \varepsilon)^2.$$  

Thus the lower bound is uniquely attained for $Y := \text{diag}(d_i)$ with

$$d_i := \begin{cases} \lambda_i & \text{if } \lambda_i \in [\varepsilon, \overline{\varepsilon}], \\ \overline{\varepsilon} & \text{if } \lambda_i > \overline{\varepsilon}, \\ \varepsilon & \text{if } \lambda_i < \varepsilon. \end{cases}$$  

□

4.2 Existence

After giving the needed definitions from matrix calculus, the goal of this subsection is now to apply Theorem 3.3 to the regularization functional defined in (1.2) with the set $K = \text{SPD}^\otimes_d$ defined in (4.1) and associated log-Euclidean metric defined below in (4.6). Therefore, we need to prove the equivalence of the log-Euclidean and Euclidean metric to guarantee in particular that Assumption 2.1(v) is fulfilled. Then Assumption 3.1 holds true as stated in Remark 3.2, and therefore Theorem 3.3 is applicable.

We start by defining and reviewing some properties of the log-Euclidean metric.

Definition 4.6 (Log-Euclidean metric). Let $A, B \in \text{SPD}$. The log-Euclidean metric is defined as

$$d_{\text{SPD}}(A, B) := d(A, B) := \|\log(A) - \log(B)\|_F, \quad A, B \in \text{SPD}. \quad (4.6)$$

Lemma 4.7. The log-Euclidean metric satisfies the metric axioms on $\text{SPD}$.

Proof. This follows directly because $\|\cdot\|_F$ is a norm and Log restricted to $\text{SPD}$ is a diffeomorphism. \hfill $\Box$

The reasons for choosing this measure of distance are stated in the following remark.

Remark 4.8. The log-Euclidean metric arises when considering $\text{SPD}$ not just as convex cone in the vector space of matrices but as a Riemannian manifold. Thus it can be endowed with a Riemannian metric defined by an inner product on the tangent space, see for example [3, 18, 38]. Two widely used geodesic distances are the affine-invariant metric

$$d_{\text{AI}}(A, B) = \|\log(A^{-1/2}BA^{-1/2})\|_F, \quad A, B \in \text{SPD}, \quad (4.7)$$

and the log-Euclidean metric as stated above. These measures of dissimilarity are more adequate in DTMRI as pointed out in [3] because zero or negative eigenvalues induce an infinite distance.

The affine-invariant distance measure is computationally much more demanding, which is a major drawback. This is not the case for the log-Euclidean distance, which leads to Euclidean distance computations in the matrix logarithmic domain.

The following statement can be found in [33, Sections 2.4 & 2.5].

Lemma 4.9. Let $d = d_{\text{SPD}}$ denote the log-Euclidean metric (as defined in (4.6)), $d_{\text{AI}}$ the affine-invariant metric (as defined in (4.7)) and $d_{\text{R}^{m \times m}}$ the standard Euclidean distance. Then $(\text{SPD}, d)$ as well as $(\text{SPD}, d_{\text{AI}})$ form a complete metric space. This is not the case for $(\text{SPD}, d_{\text{R}^{m \times m}})$.

Different metrics induce different properties on the corresponding regularizer. We compare $\Phi^l_{[d_{\text{R}^{m \times m}}]}$, $\Phi^l_{[d_{\text{SPD}}]}$ and additionally a Sobolev semi-norm regularizer in the following.

Remark 4.10 (Invariances). For the log-Euclidean metric $d = d_{\text{SPD}}$ as defined in (4.6), the following holds true.

- **Scale invariance:** Let $c > 0$ and $A, B \in \text{SPD}$, and denote by $\mathbb{1}_m$ the identity matrix in $\mathbb{R}^{m \times m}$. Then
  $$d(cA, cB) = d(c\mathbb{1}_mA, c\mathbb{1}_mB) = \|\log(c\mathbb{1}_m) + \log(A) - \log(c\mathbb{1}_m) - \log(B)\|_F = d(A, B).$$

- **Invariance under inversion:** Let $A, B \in \text{SPD}$. Because $\log(A^{-1}) = -\log(A)$, we directly get that
  $$d(A^{-1}, B^{-1}) = d(A, B).$$

- **Unitary invariance:** Let $A, B \in \text{SPD}$ and $U$ unitary. Because of the unitary invariance of the Frobenius norm, then
  $$d(UAU^T, UBU^T) = d(A, B).$$

These properties transfer to our regularizer $\Phi^l_{[d]}$ over $W^{s,p}(\Omega; \text{SPD})$. Clearly, when considering $\Phi^l_{[d_{\text{R}^{m \times m}}]}$, where $d_{\text{R}^{m \times m}}(A, B) = \|A - B\|_F$ is the standard Euclidean distance, the first two properties do not hold true in contrast to the unitary invariance which is also valid.
Note that the reverse embedding in the previous lemma does not hold (or is not even well-defined) for our regularizer $\Phi^f_{d_{g_{mn}}}$ and the regularization term $\Theta$. Although we only work with fractional derivatives of order $s \in (0, 1)$, we consider for comparison purposes the regularization functional (see also (6.1))

$$w \in W^{1,p}(\Omega, \mathbb{R}^{m \times m}) \mapsto \Theta(w) := \int_{\Omega} \|\nabla w(x)\|_F^p \, dx.$$  

None of the invariances above, i.e. scale invariance, inversion under inversion and unitary invariance, is valid for $\Theta$. Instead,

$$\Theta(w + C) = \Theta(w), \quad \Theta(w) = \Theta(-w)$$

for some constant matrix $C \in \mathbb{R}^{m \times m}$, i.e. it is translation and reflection invariant. This, in turn, does not hold (or is not even well-defined) for our regularizer $\Phi^f_{d_{g}}$ with the log-Euclidean metric but as well when considering the standard Euclidean distance, i.e. it does hold for $\Phi^f_{d_{g_{mn}}}$.

A comparison is shown in Table 1.

### Table 1: Comparison of invariance properties of our regularizer $\Phi^f_{d_{g}}$, $\Phi^f_{d_{g_{mn}}}$ and the regularization term $\Theta$.

| Invariance Type        | $\Phi^f_{d_{g}}$ | $\Phi^f_{d_{g_{mn}}}$ | $\Theta$ |
|------------------------|------------------|------------------------|---------|
| Scale invariant        | ✓                | ✓                      | ✗       |
| Inversion invariant    | ✓                | ✓                      | ✗       |
| Unitary invariant      | ✓                | ✓                      | ✓       |
| Translation invariant  | ✗                | ✓                      | ✓       |
| Reflection invariant   | ✗                | ✓                      | ✓       |

In order to show that Theorem 3.3 is applicable for $\mathcal{F}^*_{\ell^w, d}$ defined in (1.2) with $K = \text{SPD}^\log_2$ and associated log-Euclidean metric $d = d_{\text{SPD}}$ defined in (4.6), we have to show that Assumption 3.1 and therefore Assumption 2.1, in particular the equivalence stated in (v), is valid. In order to prove that, we need the following corollary.

**Corollary 4.11.** Let $A \in \text{SPD}^\log_2$ (defined in (2.3)) with eigenvalues $(\lambda_i)_{i=1}^m$. Then, for each $i = 1, \ldots, m$,

$$\lambda_i \in [e^{-2}, e^2],$$

i.e. $\text{SPD}^\log_2 \subset \text{SPD}^\text{spec}_{[e^{-2}, e^2]}$ (for the definition of the latter set, see (2.2)).

**Proof.** If $A \in \text{SPD}^\log_2$, it holds that $\|\operatorname{Log}(A)\|_F \leq z$. Using (4.4), this is equivalent to $\sum_{i=1}^m \log^2(\lambda_i) \leq z^2$, so the claim follows.

Note that the reverse embedding in the previous lemma does not hold true. If $A \in \text{SPD}^\text{spec}_{[e^{-2}, e^2]}$, such that, for each eigenvalue $\lambda_i, i = 1, \ldots, m$, we have that $\lambda_i \in [e^{-2}, e^2]$, then $A \in \text{SPD}^\log_{e^{-2}, e^2} \notin \text{SPD}^\log_2$.

Now we can prove that the Euclidean and the log-Euclidean metric are equivalent on $\text{SPD}^\log_2$. In particular, we show that $\operatorname{Log}$ is bi-Lipschitz on $\text{SPD}^\log_2$ and calculate the constant explicitly. Without explicit computation, this would follow from the fact that $\operatorname{Log}$ is a diffeomorphism on symmetric, positive definite matrices and that $\text{SPD}^\log_2$ is a compact subset.

**Lemma 4.12.** Let $A, B \in \text{SPD}^\log_2$ be defined in (2.3). Then

$$\frac{1}{e^2} \|A - B\|_F^2 \leq \|\operatorname{Log}(A) - \operatorname{Log}(B)\|_F^2 \leq \frac{1}{e^{-2}} \|A - B\|_F^2.$$  

**Proof.** Since $A$ and $B$ are symmetric and positive definite, they can be factorized using their eigendecomposition, see Remark 4.1 (i). Hence we can write

$$A = U\Lambda_A U^T, \quad B = V\Lambda_B V^T,$$

where $U, V \in \mathbb{R}^{m \times m}$ are unitary matrices and $\Lambda_A, \Lambda_B$ are diagonal matrices whose entries are the corresponding positive eigenvalues $(\lambda_1, \ldots, \lambda_m)$ of $A$ and $(\mu_1, \ldots, \mu_m)$ of $B$, respectively. By Corollary 4.11, it holds that $\lambda_i, \mu_i \in [e^{-2}, e^2]$ for all $i = 1, \ldots, m$. We consider two cases.
Case 1. We assume that all eigenvalues of A and B are equal, i.e. they have the same one-dimensional spectrum \( \text{spec}(A) = \text{spec}(B) = \{ \lambda \} \), meaning that \( \Lambda = \lambda \mathbb{1}_m := \Lambda_A = \Lambda_B \). This in turn gives that
\[
\|A - B\|_F^2 = \|U\Lambda U^T - V\Lambda V^T\|_F^2 = \|V^T U\Lambda - \Lambda V^T U\|_F^2 = 0,
\]
\[
\|\text{Log}(A) - \text{Log}(B)\|_F^2 = \|V^T U\log(\Lambda) - \log(\Lambda) V^T U\|_F^2 = \|V^T U\log(\lambda) - \log(\lambda) V^T U\|_F^2 = 0,
\]
using the unitary invariance of the Frobenius norm as stated in (4.3) and the properties of the matrix logarithm in Definition 4.2(ii) in the second equation. Thus (4.8) is trivially fulfilled.

Case 2. We now assume that there exist at least two different eigenvalues \( \lambda_i \neq \mu_j, i, j \in \{1, \ldots, m\} \) of A and B.

We show the lower inequality \( \frac{1}{e^2}\|A - B\|_F^2 \leq \|\text{Log}(A) - \text{Log}(B)\|_F^2 \) in (4.8). The upper inequality can be done analogously.

By (4.3) and the properties of the matrix logarithm in Definition 4.2(ii), it follows that
\[
\|\text{Log}(A) - \text{Log}(B)\|_F^2 = \|V^T U\log(\Lambda) - \log(\Lambda) V^T U\|_F^2 = \|C(\text{diag}(\log(\lambda_1), \ldots, \log(\lambda_m))) - \text{diag}(\log(\mu_1), \ldots, \log(\mu_m))\|_F^2,
\]
where \( C := V^T U \). Using the definition of the Frobenius norm in (2.4), we obtain further that
\[
\|C(\text{diag}(\log(\lambda_1), \ldots, \log(\lambda_m))) - \text{diag}(\log(\mu_1), \ldots, \log(\mu_m))\|_F^2 = \sum_{i,j=1}^m |c_{ij}(\log(\lambda_i) - \log(\mu_j))|^2.
\]
Indices \( (i, j) \in \{1, \ldots, m\} \) for which \( \lambda_i = \mu_j \) do not contribute to the sum in (4.10) (and do not change the following calculation), so we define \( J := \{(i, j) \in \{1, \ldots, m\} : \lambda_i \neq \mu_j \} \) as the set of such indices \( (i, j) \in \{1, \ldots, m\} \) for which we have \( \lambda_i \neq \mu_j \).

From the mean value theorem, it follows that, for every \( (i, j) \in J \), there exists some
\[
\xi_{ij} \in \begin{cases} (\lambda_i, \mu_i) & \text{if } \lambda_i < \mu_i, \\ (\mu_i, \lambda_i) & \text{if } \mu_i < \lambda_i, \end{cases}
\]
such that
\[
\sum_{(i,j) \in J} |c_{ij}(\log(\lambda_i) - \log(\mu_i))|^2 = \sum_{(i,j) \in J} |c_{ij}\frac{1}{\xi_{ij}}(\lambda_i - \mu_i)|^2 \geq \frac{1}{e^2} \sum_{(i,j) \in J} |c_{ij}(\lambda_i - \mu_i)|^2.
\]
Further, we can write
\[
\frac{1}{e^2} \sum_{(i,j) \in J} |c_{ij}(\lambda_i - \mu_i)|^2 = \|C(\text{diag}(\lambda_1, \ldots, \lambda_m)) - \text{diag}(\mu_1, \ldots, \mu_m)\|_F^2 = \frac{1}{e^2} \|C\Lambda - A\|_F^2.
\]
Combining (4.9), (4.10), (4.11), (4.12), the definition of \( C = V^T U \) and (4.3), we obtain that
\[
\|\text{Log}(A) - \text{Log}(B)\|_F^2 \geq \frac{1}{e^2} \|C\Lambda - A\|_F^2 = \frac{1}{e^2} \|UA\Lambda U^T - VA\Lambda V^T\|_F^2 = \frac{1}{e^2} \|A - B\|_F^2,
\]
which finishes the proof.

The previous lemma, Lemma 4.12, proves that Assumption 2.1(v) is valid. This together with Remark 3.2 proves the following theorem.

**Theorem 4.13.** Let \( K = \text{SPD}^{Log} \) and \( d = d_{\text{SPD}} \) as in (4.6). Then the functional \( \mathcal{F}_{\Omega}^{\alpha,w} \) as defined in (1.2) over \( W^{s,p}(\Omega; \text{SPD}^{Log}) \) satisfies the assertions of Theorem 3.3. In particular, it attains a minimizer and fulfills a stability and convergence result.

### 4.3 Uniqueness

So far we showed that the functional \( \mathcal{F}_{\Omega}^{\alpha,w} \) as defined in (1.2) over \( W^{s,p}(\Omega; \text{SPD}^{Log}) \) using the log-Euclidean metric \( d = d_{\text{SPD}} \) as in (4.6) attains a minimizer. In this subsection, we prove that the minimum is unique. To this end, we consider the symmetric, positive definite matrices from a differential geometric point of view.

The following lemma can be found in [3] and also [39].
Lemma 4.14. The space \((\text{SPD}, d)\), where \(d = d_{\text{SPD}}\) denotes the log-Euclidean metric as defined in (4.6), is a complete, connected Riemannian manifold with zero sectional curvature.

In other words, \((\text{SPD}, d)\) is a flat Hadamard manifold and therefore in particular a Hadamard space. The last property guarantees that the metric \(d\) is geodesically convex [48, Corollary 2.5], i.e. let \(y, \eta : [0, 1] \to \text{SPD}\) be two geodesics; then

\[
d(y_t, \eta_t) \leq td(y_0, \eta_0) + (1 - t)d(y_1, \eta_1).
\]

Moreover, \(d^p\) is strictly convex in one argument for \(p > 1\) ([48, Proposition 2.3] & [4, Example 2.2.4]), i.e. for \(M \in \text{SPD}\) fixed and \(y_0 \neq y_1\),

\[
d^p(y_t, M) < td^p(y_0, M) + (1 - t)d^p(y_1, M).
\]

The following result states that connecting geodesics between two points in \(\text{SPD}^2_{\log}\) stay in this set.

Lemma 4.15. Let Assumption 3.1 hold. Let \(K = \text{SPD}^2_{\log}\), and let \(d = d_{\text{SPD}}\) be the log-Euclidean metric as defined in (4.6). Let \(w^*, w^0 \in W^{s,p}(\Omega; \text{SPD}^2_{\log}) \subset W^{s,p}(\Omega; \text{SPD})\). For \(\gamma : \Omega \times [0, 1] \to \text{SPD}\), define

\[
y^* := y(x, \cdot) : [0, 1] \to W^{s,p}(\Omega; \text{SPD}),
\]

as a connecting geodesic between \(y^*(0) = w^*(x)\), and \(y^*(1) = w^0(x)\) and

\[
y_t := y(\cdot, t) : \Omega \to W^{s,p}(\Omega; \text{SPD}),
\]

as the evaluation of the geodesic between \(w^*(x)\) and \(w^0(x)\) at time \(t\) for \(x \in \Omega\). Then \(y_t \in W^{s,p}(\Omega; \text{SPD}^2_{\log})\).

Proof. We split the proof into two parts. First we show that \(y_t\) maps indeed into \(\text{SPD}^2_{\log}\). Afterwards, we prove that it actually lies in \(W^{s,p}(\Omega; \text{SPD}^2_{\log})\).

The geodesic \(y_t\) connects \(y_0(x) = w^*(x)\) and \(y_1(x) = w^0(x)\) for \(x \in \Omega\). Therefore ([47, Chapter 3.5] and [3]), it can be written as

\[
y_t(x) = \text{Exp}(t \log(w^*(x)) + (1 - t) \log(w^0(x)))
\]

which is equivalent to

\[
\log(y_t(x)) = t \log(w^*(x)) + (1 - t) \log(w^0(x)).
\]

We denote by \(1_m\) the identity matrix of size \(m \times m\) and note that \(\|\log(y_t(x))\|_F = d(y_0(\cdot), 1_m)\), where the Log-Euclidean metric \(d\) is as defined in (4.6). Because of the geodesic convexity, see (4.13), we obtain that

\[
\|\log(y_t(x))\|_F = d(y_t(x), 1_m) \leq t d(y_0(\cdot), 1_m) + (1-t)d(y_1(\cdot), 1_m) = tz + (1-t)z = z
\]

because \(w^*, w^0 \in W^{s,p}(\Omega; \text{SPD}^2_{\log})\), i.e. \(\|\log(w^0)\|_F \leq z\|\log(w^0)\|_F \leq z\). This shows that \(y_t\) maps into \(\text{SPD}^2_{\log}\).

Next we need to prove that actually \(y_t \in W^{s,p}(\Omega; \text{SPD}^2_{\log})\), i.e. that

\[
\|y_t\|_{W^{s,p}(\Omega; \text{SPD}^2_{\log})}^p = \int_\Omega \|y_t(x)\|_F^p \, dx + \int_{\Omega \times \Omega} \frac{\|y_t(x) - y_t(y)\|_F^p}{|x - y|^{1 + ps}} \, dx \, dy < \infty.
\]

We obtain by Jensen’s inequality that

\[
\|y_t\|_{W^{s,p}(\Omega; \text{SPD}^2_{\log})}^p \leq 2^{p-1} \left( \int_\Omega \|y_t(x) - 1_m\|_F^p \, dx + \int_\Omega \|1_m\|_F^p \, dx \right) + \Phi_0^{d_{\text{diam}}} (y_t) < \infty.
\]

Using (4.8), it follows that

\[
2^{p-1} \left( \int_\Omega \|y_t(x) - 1_m\|_F^p \, dx + \int_\Omega \|1_m\|_F^p \, dx \right) + \Phi_0^{d_{\text{diam}}} (y_t) 
\]

\[
\leq 2^{p-1} (e^\varepsilon)^{p/2} \left( \int_\Omega d^p(y_t(x), 1_m) \, dx + \Phi_0^{d_{\text{diam}}} (y_t) \right) + C,
\]
where \( C := 2^{p-1} |\Omega| \). By using the geodesic convexity stated in (4.13) and (4.14) and again the equivalence of the Euclidean and the log-Euclidean metric (see Lemma 4.12), we get that

\[
2^{p-1}(e^2)^{p/2} \left( \int_\Omega d^p(y_t(x), \mathbb{I}_m) \, dx + \Phi^0_{d|}(y_t) \right) + C \\
\leq 2^{p-1}(e^2)^{p/2} \left( \int_\Omega d^p(y_0(x), \mathbb{I}_m) \, dx + (1-t) \int_\Omega d^p(y_1(x), \mathbb{I}_m) \, dx \\
+ t \Phi^0_{d|}(y_0) + (1-t) \Phi^0_{d|}(y_1) \right) + C \\
\leq 2^{p-1}e^{p/2} \left( \int_\Omega \|y_0(x) - \mathbb{I}_m\|_F^p \, dx + (1-t) \int_\Omega \|y_1(x) - \mathbb{I}_m\|_F^p \, dx \\
+ t \Phi^0_{d_{\text{asym}}} (y_0) + (1-t) \Phi^0_{d_{\text{asym}}} (y_1) \right) + C.
\]

The last expression is finite because of the assumption that \( w^*, w^\circ \in W^{s,p}(\Omega; \text{SPD}^2_{\log}) \).

Now we can state the uniqueness result.

**Theorem 4.16.** Let Assumption 3.1 hold. Let \( K = \text{SPD}^2_{\log} \) and let \( d = d_{\text{SPD}} \) be the log-Euclidean metric as defined in (4.6). Then the functional \( \mathcal{J}^\alpha_{d|} \) as defined in (1.2) on \( W^{s,p}(\Omega; \text{SPD}^2_{\log}) \) attains a unique minimizer.

**Proof.** Existence of a minimizer is guaranteed by Theorem 4.13. Now, let us assume that there exist two minimizers \( w^* \neq w^\circ \in W^{s,p}(\Omega; \text{SPD}^2_{\log}) \) of the functional \( \mathcal{J}^\alpha_{d|} \).

Analogously as in Lemma 4.15 for a geodesic path \( y : \Omega \times [0,1] \rightarrow \text{SPD} \) connecting \( w^* \) and \( w^\circ \), we denote \( y_t = y(\cdot, t) \) for \( t \in [0,1] \). Thus, in particular, \( w^* (x) = y_0(x) \) and \( w^\circ (x) = y_1(x) \) for \( x \in \Omega \). Especially, \( y_t \in W^{s,p}(\Omega; \text{SPD}^2_{\log}) \) (see Lemma 4.15).

Because \( w^\circ \) is fixed, \( d \) is strictly convex in one argument by (4.14) and convex in both arguments by (4.13), it follows that

\[
\mathcal{J}^\alpha_{d|} (y_t) = \left[ \int_{\Omega \times \mathbb{D}} d^p(y_t(x), w^\circ(x)) \, dx + \alpha \int_{\Omega \times \mathbb{D}} \frac{d^p(y_t(x), y_t(y))}{|x-y|_F^{s+p}} \rho_d(x-y) \, d(x,y) \right] \\
< t \mathcal{J}^\alpha_{d|} (y_0) + (1-t) \mathcal{J}^\alpha_{d|} (y_1). \tag{4.15}
\]

Because \( w^* \) and \( w^\circ \) are both minimizers, we have that

\[
\mathcal{J}^\alpha_{d|}(w^*) = \mathcal{J}^\alpha_{d|}(w^\circ) = \mathcal{J}^\alpha_{d|}(y_0) = \mathcal{J}^\alpha_{d|}(y_1) = \mathcal{J}^\alpha_{d|}(w^\circ).
\]

In particular, for \( t = 1/2 \), we obtain by the above equality and by (4.15) that

\[
\mathcal{J}^\alpha_{d|}(y_{1/2}) < \frac{1}{2} \mathcal{J}^\alpha_{d|}(y_0) + \frac{1}{2} \mathcal{J}^\alpha_{d|}(y_1) = \mathcal{J}^\alpha_{d|}(y_0) = \min_{w \in W^{s,p}(\Omega; \text{SPD}^2_{\log})} \mathcal{J}^\alpha_{d|}(w),
\]

which is a contradiction to the minimizing property of \( w^* (x) = y_0(x) \) and \( w^\circ (x) = y_1(x) \) for \( x \in \Omega \). Hence \( y_0 \) and \( y_1 \) must be equal forcing equality in (4.15) and thus giving that the minimum is unique. \( \square \)

**Existence and uniqueness in the case \( sp > n \)**

If \( sp > n \), then existence and uniqueness of the minimizer of the functional \( \mathcal{J}^\alpha_{d|} \) even holds on the larger set \( W^{s,p}(\Omega; \text{SPD}) \) rather than on \( W^{s,p}(\Omega; \text{SPD}^2_{\log}) \), where \( \text{SPD} \) is associated with the log-Euclidean distance \( d = d_{\text{SPD}} \) as defined in (4.6). Existence in Theorem 4.13 and uniqueness in Theorem 4.16 (with \( K = \text{SPD}^2_{\log} \)) are based on the theory provided in [14] (see Theorem 3.3), where it is a necessary assumption that the set \( K \) is closed which is not the case for the set \( \text{SPD} \).

Nevertheless, it is possible to get existence and uniqueness on this set because, for every minimizing sequence \( w_k \in W^{s,p}(\Omega; \text{SPD}) \), \( k \in \mathbb{N} \), we automatically get that \( w_k \in W^{s,p}(\Omega; \text{SPD}^2_{\log}) \) so that it takes values
on the closed subset $\text{SPD}_{\log}^2$. Then existence of a unique minimizer on $W^{s,p}(\Omega; \text{SPD})$ follows by the proofs already given, see [14, Theorem 3.6] and Theorem 4.16.

We now sketch the proof of the assertion. Throughout this sketch, $C$ denotes a finite generic constant which, however, can be different from line to line.

**Sketch of assertion.** Denote by $d = d_{\text{SPD}}$ the log-Euclidean metric (as defined in (4.6)). Let us take a minimizing sequence $w_k \in W^{s,p}(\Omega; \text{SPD})$, $k \in \mathbb{N}$, of $\mathcal{F}_{[d]}^{a,w_d}$ so that we can assume that $\mathcal{F}_{[d]}^{a,w_d}(w_k) \leq C$ for all $w_k$, $k \geq k_0 \in \mathbb{N}$.

Computing the log-Euclidean metric leads to evaluations of the Euclidean metric in the matrix logarithmic domain, cf. (4.6), meaning that

$$d(A, B) = \| \log(A) - \log(B) \|_F = d_{\text{vec}(\log(A), \log(B))}, \quad A, B \in \text{SPD}.$$ 

Because of this and the fact that $w^d \in L^p(\Omega; \text{SPD})$, we get that

$$C \geq \| \log(w_k) \|_{L^p(\Omega; \text{SYM})} + a \delta_{d_{\text{vec}(\log)}}(\log(w_k)).$$

Because of [32, Lemma 2.7], we can thus bound the $W^{s,p}$-norm of $\log(w_k)$,

$$C \geq \| \log(w_k) \|_{W^{s,p}(\Omega; \text{SYM})}.$$  \hspace{1cm} (4.16)

If $sp > n$, the space $W^{s,p}(\Omega; \mathbb{R}^{m \times m})$ is embedded into Hölder spaces $C^{0, \alpha'}(\Omega; \mathbb{R}^{m \times m})$ with $\alpha' := (sp - n)/p$ guaranteed by [17, Theorem 8.2]. Because of (4.16), this gives us that

$$C \geq \| \log(w_k) \|_{C^{0, \alpha'}(\Omega; \text{SYM})},$$

yielding in particular that $\| \log(w_k) \|_{\infty} < C := z$.

By the definition of $\text{SPD}_{\log}^2$ in (2.3), we thus obtain that $w_k \in W^{s,p}(\Omega; \text{SPD}_{\log}^2)$ for all $k \geq k_0$. Hence every minimizing sequence $w_k \in W^{s,p}(\Omega; \text{SPD})$, $k \in \mathbb{N}$, of $\mathcal{F}_{[d]}^{a,w_d}$ is automatically a minimizing sequence in $W^{s,p}(\Omega; \text{SPD}_{\log}^2)$.

### 5 Numerics

In this section, we go into more detail on the minimization of the regularization functional $\mathcal{F}_{[d]}^{a,w_d}$ defined in (1.2) with the log-Euclidean metric $d = d_{\text{SPD}}$ as defined in (4.6) (see [3]) over the set $K = \text{SPD}_{\log}^2$, the set of symmetric, positive definite $m \times m$ matrices with bounded logarithm, as defined in (4.1) for denoising and inpainting of DTMRI images.

To optimize $\mathcal{F}_{[d]}^{a,w_d}$, we use a projected gradient descent algorithm. The implementation is done in Matlab. The gradient step is performed by using Matlab’s built-in function $\text{fminunc}$, where the gradient is approximated with a finite difference scheme (central differences in the interior and one-sided differences at the boundary). Therefore, after each step, we project the data which are elements of the larger space $\text{SYM}$ (3) back onto $K = \text{SPD}_{\log}^2(3)$ by applying the following projection. We remark that, by projection, we here refer to an idempotent mapping.

### 5.1 Projections

**Definition 5.1 (Projection operators).** We define the following projections.

- **Projection of $\text{SYM}$ onto $\text{SPD}_{\text{spec}}(\varepsilon, \infty)$:** Let $M \in \text{SYM}$ be a symmetric matrix with eigendecomposition $M = V \Lambda V^T$ with $\Lambda = \text{diag}(\Lambda_1, \ldots, \Lambda_m)$. Then the projection of $M$ onto the set $\text{SPD}_{\text{spec}}(\varepsilon, \infty)$ is given by

$$P_1 : \text{SYM} \to \text{SPD}_{\text{spec}}(\varepsilon, \infty), \quad M \mapsto V \Sigma V^T,$$  \hspace{1cm} (5.1)
Lemma 5.2. The following statements hold.

(i) Let \( w \in W^{s,p}(\Omega; \text{SYM}) \). Then \( P_1(w) \in W^{s,p}(\Omega; \text{SPD}_{(\varepsilon,\infty)}^\text{spec}) \).

(ii) Let \( w \in W^{s,p}(\Omega; \text{SPD}_{(\varepsilon,\infty)}^\text{spec}) \). Then \( P_2(w) \in W^{s,p}(\Omega; \text{SPD}_{\Sigma}^\text{Log}) \).

(iii) Let \( w \in W^{s,p}(\Omega; \text{SYM}) \). Then \( P(w) \in W^{s,p}(\Omega; \text{SPD}_{\Sigma}^\text{Log}) \).

Proof. (i) Let \( w \in W^{s,p}(\Omega; \text{SYM}(m)) \), and define \( v := P_1(w) \). By the definition of \( P_1 \), it follows directly that \( v : \Omega \to \text{SPD}_{(\varepsilon,\infty)}(m) \).

By Remark 4.1 (i) and the definition of \( P_1 \) (see (5.1) and also Lemma 4.5), we can decompose \( w(x) \) and \( v(x) \) for \( x \in \Omega \) as follows:

\[
w(x) = R(x) W(x) R^T(x), \quad v(x) = R(x) V(x) R^T(x),
\]

with orthonormal matrix \( R \in \mathbb{R}^{m \times m} \) and diagonal matrices \( W, V \in \mathbb{R}^{m \times m} \). Denote the eigenvalues of \( w(x) \) as \( (\lambda_i(x))_{i=1}^m \). The eigenvalues of \( v(x) \) are then defined as

\[
\mu_i(x) := \begin{cases} 
\lambda_i(x) & \text{if } \lambda_i(x) \in [\varepsilon, \infty), \\
\varepsilon & \text{if } \lambda_i(x) < \varepsilon,
\end{cases} \quad i = 1, \ldots, m.
\]

where \( \Sigma = \text{diag}(\mu_1, \ldots, \mu_m) \) with

\[
\mu_i := \begin{cases} 
\lambda_i & \text{if } \lambda_i \geq \varepsilon, \\
\varepsilon & \text{if } \lambda_i < \varepsilon.
\end{cases}
\]

- **Projection of SPD\(_{(\varepsilon,\infty)}^\text{spec} \)** onto SPD\(_{\Sigma}^\text{Log} \): Let \( M \in \text{SPD}_{(\varepsilon,\infty)}^\text{spec} \) with eigenvalues \( (\lambda_i)_{i=1}^m \) and eigendecomposition \( M = V \Lambda V^T \). Define

\[
C_{\text{Frob}} := \| \log(M) \|_F^2 = \sum_{i=1}^m \log^2(\lambda_i)
\]

as the squared Frobenius norm of \( \log(M) \). Then the projection of \( M \) onto SPD\(_{\Sigma}^\text{Log} \) is given by

\[
P_2 : \text{SPD}_{(\varepsilon,\infty)}^\text{spec} \to \text{SPD}_{\Sigma}^\text{Log}, \quad M \mapsto V \Sigma V^T,
\]

where \( \Sigma = \text{diag}(\mu_1, \ldots, \mu_m) \) with

\[
\mu := \begin{cases} 
\lambda & \text{if } C_{\text{Frob}} \leq z^2, \\
\lambda^{1/\sqrt{C_{\text{Frob}}}} & \text{if } C_{\text{Frob}} > z^2,
\end{cases}
\]

where \( \lambda = (\lambda_1, \ldots, \lambda_m)^T \) and \( \mu = (\mu_1, \ldots, \mu_m)^T \) are the vectors containing all eigenvalues.

- **Projection of SYM onto SPD\(_{\Sigma}^\text{Log} \)**: Let \( M \in \text{SYM} \) be a symmetric matrix. We define its projection \( P(M) \) onto SPD\(_{\Sigma}^\text{Log} \) as

\[
P : \text{SYM} \to \text{SPD}_{\Sigma}^\text{Log}, \quad M \mapsto P_2(P_1(M)).
\]

For a given matrix \( M \in \text{SYM} \), the projection \( P_1(M) \in \text{SPD}_{(\varepsilon,\infty)}^\text{spec} \) is the closest approximation in the Frobenius norm, i.e.

\[
P_1(M) = \arg \min_{X \in \text{SPD}_{(\varepsilon,\infty)}^\text{spec}} \| M - X \|_F^2,
\]

as stated in Lemma 4.5 when choosing \( \varepsilon = \varepsilon \) and \( \infty = \infty \).

If \( M \in \text{SPD}_{(\varepsilon,\infty)}^\text{spec} \), the projection \( P_2 \) scales the eigenvalues of \( M \) in such a way that it is guaranteed that

\[
\| \log(P_2(M)) \|_F \leq z, \quad \text{i.e. } P_2(M) \in \text{SPD}_{\Sigma}^\text{Log}.
\]

In fact, if \( C_{\text{Frob}} = \| \log(M) \|_F^2 > z^2 \) meaning that \( M \notin \text{SPD}_{\Sigma}^\text{Log} \), then

\[
\| \log(P_2(M)) \|_F^2 = \sum_{i=1}^m \log^2(\lambda_i/\sqrt{C_{\text{Frob}}}) = \frac{z^2}{C_{\text{Frob}}} \sum_{i=1}^m \log^2(\lambda_i) = \frac{z^2}{C_{\text{Frob}}} \| \log(M) \|_F^2 = z^2,
\]

giving that \( P_2(M) \in \text{SPD}_{\Sigma}^\text{Log} \).

The following lemma shows that the projected functions stay in the same regularity class.

**Lemma 5.2.** The following statements hold.

(i) Let \( w \in W^{s,p}(\Omega; \text{SYM}) \). Then \( P_1(w) \in W^{s,p}(\Omega; \text{SPD}_{(\varepsilon,\infty)}^\text{spec}) \).

(ii) Let \( w \in W^{s,p}(\Omega; \text{SPD}_{(\varepsilon,\infty)}^\text{spec}) \). Then \( P_2(w) \in W^{s,p}(\Omega; \text{SPD}_{\Sigma}^\text{Log}) \).

(iii) Let \( w \in W^{s,p}(\Omega; \text{SYM}) \). Then \( P(w) \in W^{s,p}(\Omega; \text{SPD}_{\Sigma}^\text{Log}) \).
It remains to show that $v \in W^{s,p}(\Omega; \text{SPD}^{\text{spec}}_{(c, \infty)}(m))$, i.e.

$$
\|v\|_{W^{s,p}(\Omega; \text{R}^{m \times m})}^p = \int_{\Omega} \|v(y)\|^p_{F} \, dx + \int_{\Omega \times \Omega} \frac{\|v(x) - v(y)\|^2_{F}}{|x-y|^{n+ps}} \, d(x,y) < \infty. \tag{5.4}
$$

We start to bound the $L^p$-norm in (5.4). For each $x \in \Omega$, it holds that

$$
\|v(x)\|_{F}^p = \|R(x) V(x) R^T(x)\|_{F}^p = \|V(x)\|_{F}^p = \left( \sum_{i=1}^{m} |\mu_i(x)|^2 \right)^{p/2}, \tag{5.5}
$$

using the unitary invariance of the Frobenius norm, see (4.3). From the definition of the $m$ eigenvalues in (5.3) and Jensen’s inequality, it follows that

$$
\left( \sum_{i=1}^{m} |\mu_i(x)|^2 \right)^{p/2} = \left( \sum_{\{i, \mu_i \neq c\}} |\mu_i(x)|^2 + \sum_{\{i, \mu_i = c\}} |\mu_i(x)|^2 \right)^{p/2} \leq 2^{p-1} (me^2)^{p/2} + 2^{p-1} \left( \sum_{i=1}^{m} |\lambda_i(x)|^2 \right)^{p/2}. \tag{5.6}
$$

We thus obtain using (5.5) and (5.6) that

$$
\|v\|_{L^p(\Omega; \text{R}^{m \times m})}^p = \int_{\Omega} \left( \sum_{i=1}^{m} |\mu_i(x)|^2 \right)^{p/2} \, dx \leq 2^{p-1} \int_{\Omega} \left( me^2 \right)^{p/2} + \left( \sum_{i=1}^{m} |\lambda_i(x)|^2 \right)^{p/2} \, dx
$$

$$
\leq 2^{p-1} (me^2)^{p/2} |\Omega| + 2^{p-1} |w|_{L^p(\Omega; \text{R}^{m \times m})}^p < \infty
$$

because $\Omega$ is bounded and $w \in W^{s,p}(\Omega; \text{SYM}(m))$, in particular $w \in L^p(\Omega; \text{SYM}(m))$. The $W^{s,p}$-semi-norm in (5.4) can be bounded in a similar way.

Therefore, we calculate, for $x, y \in \Omega$,

$$
\|v(x) - v(y)\|^p_{F} = \|R(x) V(x) R^T(x) - R(y) V(y) R^T(y)\|^p_{F} = \| R^T(y) R(x) V(x) - V(y) R^T(y) R(x) \|^p_{F}
$$

$$
= : \|C(x, y) V(x) - V(y) C(x, y)\|^p_{F} = \left( \sum_{i,j=1}^{m} c_{ij}(x, y)(\mu_i(x) - \mu_i(y))^2 \right)^{p/2}, \tag{5.7}
$$

where the last equality holds true because the matrix $C$ is symmetric. The same calculation is valid for $w$ so that we obtain

$$
\|w(x) - w(y)\|^p_{F} = \left( \sum_{i,j=1}^{m} c_{ij}(x, y)(\lambda_i(x) - \lambda_i(y))^2 \right)^{p/2}. \tag{5.8}
$$

By the definition of the eigenvalues $\mu$, see (5.3), and by using a splitting of the sum as in (5.6), it can be shown that

$$
\left( \sum_{i,j=1}^{m} c_{ij}(x, y)(\mu_i(x) - \mu_i(y))^2 \right)^{p/2} \leq \left( \sum_{i,j=1}^{m} c_{ij}(x, y)(\lambda_i(x) - \lambda_i(y))^2 \right)^{p/2}. \tag{5.9}
$$

This implies that (using (5.7), (5.8), (5.9))

$$
|v|_{W^{s,p}(\Omega; \text{R}^{m \times m})} = \int_{\Omega \times \Omega} \frac{\|v(x) - v(y)\|^p_{F}}{|x-y|^{n+ps}} \, d(x,y)
$$

$$
= \int_{\Omega \times \Omega} \frac{\left( \sum_{i,j=1}^{m} c_{ij}(x, y)(\mu_i(x) - \mu_i(y))^2 \right)^{p/2}}{|x-y|^{n+ps}} \, d(x,y)
$$

$$
\leq \int_{\Omega \times \Omega} \frac{\left( \sum_{i,j=1}^{m} c_{ij}(x, y)(\lambda_i(x) - \lambda_i(y))^2 \right)^{p/2}}{|x-y|^{n+ps}} \, d(x,y)
$$

$$
= |w|_{W^{s,p}(\Omega; \text{R}^{m \times m})} < \infty
$$

because of the fact that $w \in W^{s,p}(\Omega; \text{SYM}(m))$. 
The next lemma shows that minimizing elements of \( \mathcal{J}_{\mathcal{F}^d}^{\alpha, w} \) on \( W^{s, p}(\Omega; \text{SPD}_z^{\log}) \) and minimizing elements of the projected gradient method are connected. Therefore, we define an extension of Remark 5.4. Basically, the second item of the previous lemma shows that the proof is straightforward.

Lemma 5.3. Let \( K = \text{SPD}_z^{\log} \), and let \( d = d_{\text{SPD}} \) be the log-Euclidean metric as defined in (4.6).

(i) Let \( w^* \in \arg\min_{w \in W^{s, p}(\Omega; \text{SPD}_z^{\log})} \mathcal{J}_{\mathcal{F}^d}^{\alpha, w}(w) \). Then, in particular, \( w^* \in W^{s, p}(\Omega; \text{SYM}) \), and it is a minimizer of \( \mathcal{J}_{\mathcal{F}^d}^{\alpha, w} \), i.e.

\[
\mathcal{J}_{\mathcal{F}^d}^{\alpha, w}(w^*) = \inf_{u \in W^{s, p}(\Omega; \text{SYM})} \mathcal{J}_{\mathcal{F}^d}^{\alpha, w}(u).
\]

(ii) Let \( u^* \in \arg\min_{u \in W^{s, p}(\Omega; \text{SYM})} \mathcal{J}_{\mathcal{F}^d}^{\alpha, w}(u) \). Then \( w^* = P(u^*) \in W^{s, p}(\Omega; \text{SPD}_z^{\log}) \) is a minimizer of \( \mathcal{J}_{\mathcal{F}^d}^{\alpha, w} \), i.e.

\[
\mathcal{J}_{\mathcal{F}^d}^{\alpha, w}(w^*) = \inf_{w \in W^{s, p}(\Omega; \text{SPD}_z^{\log})} \mathcal{J}_{\mathcal{F}^d}^{\alpha, w}(w).
\]

The proof is straightforward.

Remark 5.4. Basically, the second item of the previous lemma shows that

\[
\arg\min_{u \in W^{s, p}(\Omega; \text{SYM})} \mathcal{J}_{\mathcal{F}^d}^{\alpha, w}(u) = P^{-1}(\arg\min_{w \in W^{s, p}(\Omega; \text{SPD}_z^{\log})} \mathcal{J}_{\mathcal{F}^d}^{\alpha, w}(w)).
\]

6 Numerical experiments

After clarifying existence, uniqueness, stability and convergence of variational regularization methods in an infinite-dimensional function set setting, we move to the discretized optimization problems, which are finite-dimensional optimization problems on manifolds. In order to present and evaluate our numerical experiments, we need a method of comparison, which is outlined in Section 6.2, and a quality criterion, which is described in Section 6.3. We present experiments with synthetic and real data in Section 6.6. The generation of synthetic data is described in Section 6.4.

When minimizing \( \mathcal{J}_{\mathcal{F}^d}^{\alpha, w} \), we follow the concept of discretize-then-optimize. So, in the text below, when we talk about numerical implementation, the functional should always be considered as a discretized functional on a finite-dimensional subset of \( W^{s, p}(\Omega; \text{SPD}_z^{\log}) \). Nevertheless, we write the functional as it is defined in the infinite-dimensional setting. However, we recall again the fundamental difference between the infinite-dimensional setting and the discretized one: after discretization, the functional deals with mappings from a vector (with dimension of the numbers of pixel) into a product vector of manifold-valued components, that is an optimization problem on manifolds. Such a formulation is not possible for the infinite-dimensional one.

The numerical results build up on the following parameter setting.

(i) In the concrete examples in Section 6.6, we take \( m = 3 \) and \( n = 2 \). This means that we manipulate (denoise and inpaint) a two-dimensional slice of a three-dimensional DT Sa MRI image.

(ii) In the regularization term \( \Phi_{\mathcal{F}^d}^{l, \alpha} \), defined in (1.1), we choose \( l = 1 \) in order to take advantage of the locally supported mollifier, see Definition 2.2.
6.1 Optimization

As described in Section 5.1, when optimizing the functional $J^{\alpha, \psi}_{[d]}$ (defined in (1.2) and $d = d_{\text{SPD}}$ defined in (4.6)), we use a projected gradient descent algorithm by applying the projection $P = P_2 \circ P_1$ to each diffusion tensor after each step (as defined in (5.2)).

First, $P_1$ projects onto the set $\text{SPD}^{\text{spec}}_{\{\varepsilon, \infty\}} (3)$. In the implementation, we used $\varepsilon = \text{eps}$, where $\text{eps}$ is the floating-point relative accuracy in Matlab. Then $P_2$ projects onto $\text{SPD}^{\text{Log}}_z (3)$, where we used $z = 36$. This is due to the fact that if $A \in \text{SPD}^{\text{Log}}_z (3)$, then its eigenvalues lie in the interval $[e^{-36}, e^{36}] \approx [\text{eps}, e^{36}]$, see Corollary 4.11, so that we are able to compute diffusion tensors close to zero without projecting them. A summary of parameters used is shown in Table 2.

The (discrete) mollifier $\rho$ in (1.2) (we choose $l = 1$) is defined in such a way that it has non-zero support on up to nine neighboring pixels in each direction. The number of non-zero elements is denoted by $n_\rho$, and we refer to Figure 1 for an illustration. The function $\rho : \mathbb{R}^n \rightarrow \mathbb{R}$ satisfies two needs. On the one hand, it allows to combine two different concepts. The characterization theory of [11] and a classical theory of Sobolev spaces [31]. On the other hand, there is a practical aspect, which is related to computation time: the smaller the essential support of $\rho$ is, the faster the optimization algorithm can be implemented. In other words, a large support would be desired for a quasi-Sobolev norm regularization implementation, but this hinders a very efficient implementation.

![Figure 1: Support of the discrete mollifier $\rho$ with $n_\rho = 1$ (gray) and $n_\rho = 2$ (black) when centered at the unfilled point in the middle. In the examples, we have chosen $n_\rho = 9$ at most.]

---

| parameter | value |
|-----------|-------|
| $\varepsilon$ | eps |
| $z$ | 36 |
| $A_0$ | 1000 |
| $b$ | 800 |
| $l$ | 1 |
| $n$ | 2 |
| $m$ | 3 |

Table 2: Parameters and corresponding values used in the numerical examples.
6.2 Comparison functional

We compare the results with the ones obtained by optimizing the comparison functional \( \mathcal{J}_c \) defined as

\[
\mathcal{J}_c(w) := \int_{\Omega} \chi_{\Omega,D}(x) \|w(x) - w^0(x)\|_F^p \, dx + \beta \int_{\Omega} \|\nabla w(x)\|_F^p \, dx
\]

on \( W^{1,p}(\Omega; \mathbb{R}^{2}) \subset W^{1,p}(\Omega; \mathbb{R}^{m,m}) \) (see [17, Corollary 5.5]). Here, the fidelity term consists of the \( L^p \)-norm, while the regularizer is the vectorial Sobolev semi-norm to the power \( p \). In the implementation, we project the data back onto \( K = \mathbb{SPD}_{\log}^3(3) \) after each gradient step as described before.

6.3 Measure of quality

As a measure of quality, we compute the signal-to-noise ratio (SNR) which is defined as

\[
\text{SNR} = \frac{\|w^{\text{orig}}\|_F}{\|w^{\text{orig}} - w^{\text{rec}}\|_F},
\]

where \( w^{\text{orig}} \) describes the ground truth and \( w^{\text{rec}} \) the reconstructed data.

6.4 Noisy data generation

We consider a discretized version of \( \Omega \subset \mathbb{R}^2 \) as a quadratic grid of size \( N \times N, N \in \mathbb{N} \), with equally distributed pixels \( \{p^{ij}\}_{i,j=1}^N \). On each \( p^{ij} \), a symmetric, positive definite diffusion tensor \( w^{ij} \in \mathbb{R}^{3 \times 3} \) (with bounded logarithm) is located describing the underlying diffusion process in the biological tissue.

In DTMRI, the actually measured data are so-called diffusion weighted images (DWIs) \( (A_{[b,g]}(p^{ij}))_{i,j=1}^N \). They describe the diffusion in a direction \( g \in \mathbb{R}^3 \) with given \( b \)-value \( b \in \mathbb{R} \) at a pixel \( p^{ij} \). The diffusion tensor and the DWIs are related by the Stejskal–Tanner equation [6, 42, 43],

\[
A_{[b,g]}(p^{ij}) = A_0 e^{-bgw^{ij}}
\]

for all pixels \( p^{ij} \), where we assume that \( A_0 \in \mathbb{R}_{>0} \) is known. For more details and a survey on MRI, see for example [26].

To generate our noisy synthetic data \( (w^\phi)^{ij} \), we computed 12 DWIs \( A_{[b,g]}^{11}(p^{ij}), \ldots, A_{[b,g]}^{12}(p^{ij}) \) from our initial (original) synthetic diffusion tensor (a symmetric, positive definite matrix with bounded logarithm) \( w^{ij} \) on each pixel \( p^{ij} \) via (6.2). Then we imposed Rician noise on them [7, 23] with different values of \( \sigma^2 \). We used a least squares fitting (as described shortly in [45]) followed by the projection \( P \) to obtain a noisy diffusion tensor image on each pixel such that \( (w^\phi)^{ij} \in \mathbb{SPD}_{\log}^3(3) \) for \( i,j \in \{1, \ldots, N\} \).

In the synthetic examples in Section 6.6.1 and Section 6.6.3, we chose \( A_0 = 1000 \) and \( b = 800 \) to generate the noisy data. The real data set in Section 6.6.4 is freely accessible [13] and provides corresponding values of \( A_0 \) and \( b \). For an overview of parameters, see Table 2.

6.5 Visualization

On each \( (p^{ij})_{i,j=1}^N \), the diffusion process is described by a symmetric, positive definite diffusion tensor \( w^{ij} \in \mathbb{R}^{3 \times 3} \) (with bounded logarithm). We visualize it by a 3D ellipsoid. Therefore, we take the (normed) eigenvectors \( \nu_1^{ij}, \nu_2^{ij}, \nu_3^{ij} \) and the corresponding eigenvalues \( \lambda_1^{ij}, \lambda_2^{ij}, \lambda_3^{ij} \) and interpret the eigenvectors as axis of an ellipsoid with length \( \lambda_1, \lambda_2 \) and \( \lambda_3 \), respectively.

We color the ellipsoids corresponding to the value of its fractional anisotropy FA defined as

\[
FA^{ij} := \sqrt{\frac{(\lambda_1^{ij} - \lambda_2^{ij})^2 + (\lambda_2^{ij} - \lambda_3^{ij})^2 + (\lambda_3^{ij} - \lambda_1^{ij})^2}{2(\lambda_1^{ij} + \lambda_2^{ij} + \lambda_3^{ij})}}, \quad i,j \in \{1, \ldots, N\}.
\]
Fractional anisotropy is an index between 0 and 1 for measuring the amount of anisotropy within a pixel. If there is no anisotropy, i.e. if the ellipsoid is sphere-shaped, then all eigenvalues are equal and the fractional anisotropy is zero, which we color black. The higher the value of FA within a pixel, the lighter blue we color the ellipsoid. A colorscale is illustrated in Figure 2.

6.6 Numerical results

Now we present concrete numerical examples for denoising and inpainting of diffusion tensor images. The diffusion tensors are represented via ellipsoids as described in Section 6.5. The parameters used are summarized in Table 2. Note that the values of $A_0$ and $b$ are only valid for the synthetic data sets; in the real data set in Figure 8, these values are provided.

6.6.1 Denoising of synthetic data

The first example is shown in Figure 3 and concerns denoising of a synthetic image in $W^{s,p}(\Omega, \text{SPD}^{\text{Log}}_{36})$. The motivation of the choice $z = 36$ was explained in Section 6.1. The noisy image is obtained by adding Rician noise to the corresponding DWIs with $\sigma^2 = 40$ as described in Section 6.4.

The original image is shown in Figure 3 (a). In a column, all ellipsoids have the same shape. In the first column, the ellipsoids shown are sphere-shaped, i.e. all eigenvalues are equal with a value of $0.5 \cdot 10^{-3}$. The fractional anisotropy (see (6.3)) is zero, and hence these ellipsoids are colored black, see Figure 2. Going from the first column to the last one, one eigenvalue is increasing from $0.5 \cdot 10^{-3}$ to $3.5 \cdot 10^{-3}$, while the other two stay constant. This leads to an increasing value of the fractional anisotropy and thus to a light blue coloring, see also Figure 2. The averaged value (over the column) of the increasing eigenvalue is plotted in black in Figure 3 (f).

The results obtained by using our metric double integral regularization (see (1.2)) can be seen in Figure 3 (c), while the results using Sobolev-semi-norm regularization (see (6.1)) are illustrated in Figure 3 (d) and (e). Our method removes the noise, while the size of the ellipsoids stays close to the size of them in the original image. This is in particular visible in Figure 3 (f), where the averaged size of the increasing eigenvalue is plotted in red. Choosing the parameter $\beta$ in the Sobolev semi-norm regularization term too small results in a quite noisy image, while a larger value of $\beta$ smooths the whole image, which can be seen particularly on the left-hand side where the ellipsoids are quite tiny. The smoothing effect is even more visible in Figure 3 (f).

The second denoising example is shown in Figure 4. It features one main direction of diffusion. The original image in $W^{s,p}(\Omega, \text{SPD}^{\text{Log}}_{36})$ is presented in Figure 4 (a), while the noisy version of it (using $\sigma^2 = 90$) can be seen in Figure 4 (b). Again, the size of the ellipsoids in each direction is as before around $10^{-3}$.

Using our regularization method, see Figure 4 (c), the noise in all areas is removed while the main direction of diffusion is recognizable. In contrast to this stands the result obtained by using the comparison functional in (6.1), see Figure 4 (d). The main direction is barely visible and noise remains, in particular in regions with tiny ellipsoids. Because the size of the ellipsoids is rather small the main contribution in the Sobolev semi-norm regularization is due to the change of size between the larger and smaller diffusion tensors. This leads to the smoothing of the whole image. Furthermore, very tiny ellipsoids barely influence the regularization term which results in the remaining noise. Compared to that our functional using the log-Euclidean metric results in a completely different behavior. In particular, in this case changes between the small ellipsoids contribute even more than the change of size.

Figure 2: Colorscale used in the numerical results. The values between 0 and 1 represent the fractional anisotropy of each ellipsoid. Here, the value zero describes a sphere.
Figure 3: Denoising of a synthetic diffusion tensor image using $p = 1.1, s = 0.5, n_{\rho} = 3$ and different values of $\alpha$ and $\beta$. 
6.6.2 Influence of parameters $p$ and $n_\rho$

In this section, we briefly go into more detail on the influence of the two parameters $p$ and $n_\rho$. We again consider the example from the previous section which features one main direction of diffusion. The original image in $W^{s,p}(\Omega, \text{SPD}_{36}^{\text{Log}}(3))$ is shown in Figure 5 (a). In all images, we use $n_\rho = 9$, i.e. a mollifier that has non-zero support on nine neighboring pixels. Moreover, we chose the same values of $\alpha = 0.3$ and $s = 0.5$ as before.

In Figure 5 (b), the parameter $p$ is set to 1.1, i.e. as in the previous example in Figure 4. As expected, an enlargement of the support of the mollifier leads to a much smoother image in total. In Figure 5 (c) and (d), we chose $p = 1.001$ and $p = 2.1$, respectively. We see that, for $p = 1.0001$, parts of the main direction of diffusion are still recognizable, i.e. the results stay closer to the original image even when using a mollifier with large support. Increasing the value of $p$ smoothes the whole image, which we also see in Figure 5 (d). By an appropriate adaption of the other parameters $s$ and $\alpha$, this effect could possibly be reduced.
6.6.3 Inpainting of synthetic data

We now come to two examples of diffusion tensor inpainting for functions in $W^{s,p}(\Omega, \text{SPD}_{\text{Log}}^3)$). We thus minimize the functional (1.2), with $D \neq 0$, which denotes the inpainting domain.

The first example, where the ground truth is represented in Figure 6 (a) has one main diffusion direction. The noisy image in Figure 6 (b) is obtained as described in Section 6.4 with variance $\sigma^2 = 90$. The area $D$ to be inpainted consists of the missing ellipsoids in the noisy data. As input data for our algorithm, we use the incomplete noisy data (as shown in Figure 6 (b)), where we replaced the missing ellipsoids (described by the null matrix $0_n$) by its projection $P(0_n)$, as defined in (5.2).

The result using our metric double integral regularization method can be seen in Figure 6 (c). The main diffusion direction is recognizable even though the size of the ellipsoids near the kink is now approximately the same. Noise, which was in particular present in the tiny ellipsoids, is removed because of the use of...
the log-Euclidean metric in our functional. Small values thus gain a high contribution. The result using the comparison functional in (6.1) is shown in Figure 6(d). The noise is removed, but it is barely possible to recognize the main diffusion direction. The whole image is smoothed. Choosing $\beta$ even smaller, the influence of the regularizer tends to zero yielding a result close to the starting image.

As second example, we consider the data shown in Figure 7. The original data is illustrated in Figure 7(a), the noisy one using $\sigma^2 = 40$ in Figure 7(b). This serves as initial data for our minimizing algorithm. The area to be inpainted, $D$, can be seen in Figure 7(c): it consists of the square of missing ellipsoids in the middle.

Using our regularization functional results in Figure 7(d). Using the Sobolev semi-norm regularization with different values of $\beta$ gives Figure 7(e) and Figure 7(f). Our result is more balanced concerning noise removal and keeping the inpainted area, in particular the size of the ellipsoids, close to the ground truth data. This is also visible in the value of the SNR. When minimizing the comparison functional in (6.1) with a small value of the regularization parameter $\beta$ the size of the ellipsoids is matched well but noise remains. Increasing of $\beta$ leads to a better noise removal with a simultaneous smoothing of the whole image.
Figure 7: Inpainting of a synthetic diffusion tensor image using $p = 1.1$, $s = 0.5$, $n_p = 2$, $\alpha = 0.5$ and $\beta = 0.5$ and $\beta = 1$, respectively.
6.6.4 Denoising of DTMRI data

In this last subsection, we present an example for denoising of a real DTMRI image. The original data are taken from [13], which is freely accessible. In this example, (parts of) the 39th slice are shown. Noise is added with $\sigma^2 = 0.05$.

In Figure 8 (c), (e) and (d), (f), respectively, parts of the whole image in Figure 8 (a) and (b), respectively, are shown. The denoised results using our regularization method can be seen in Figure 8 (g) and (h), respectively. In Figure 8 (g), we see that the structure and sizes of the ellipsoids are preserved. Nevertheless, noise is still visible in some parts. Increasing the regularization parameter $\alpha$ further leads to more noise removal accompanied by a swelling in particular of those ellipsoids in the middle of the image which have one eigenvalue close to zero. In Figure 8 (h), this effect is visible. Here, noise is removed well and the main structures are preserved, but there is a swelling of some ellipsoids.

Figure 8: Denoising of real data taken from [13] using $p = 1.1, s = 0.1, \sigma = 0.7$ and $\sigma = 0.5$, respectively, and $n_p = 1$. 
6.7 Conclusion

The contribution of this paper is the application of recently developed derivative-free, metric double integral regularization methods for denoising of diffusion tensor imaging data. The analysis is based on recent work [14] but completed by a uniqueness result for the minimizer of the regularization functional. In order to derive the analytical result, we require differential geometric results on sets of positive definite, symmetric matrices. We also demonstrate the effectiveness of the approach by some synthetic and DTMRI data.
