The method of coagulation test about the removal of humic acid and turbidity from water using PZFSIS

Coagulation tests were carried out using a ZR4-6 six-paddle gang stirrer (Shenzhen Zhongrun Water Industry Technology and Development Co., Ltd, China). A certain dosage of PZFSiS (In Fe mass, mg/L) was added into the water samples which was prepared by the stock solution of HA and the stock suspension of kaolin. Then the water was mixed at a high speed of 300 rpm for 1 min and then at a low speed of 40 rpm for 10 min. After that, the water was settled for 30 min. Turbidity and UV$_{254}$ of treated water were measured using a 2100P turbidity meter (HACH, USA) and a TU-1900 ultraviolet/visible (UV/VIS) spectrophotometer. The removal rates of turbidity and HA are calculated using Eq. (1):

$$R = (1 - T_f/T_i) \times 100\%$$  \hspace{1cm} (1)

where R are the removal rate of turbidity and HA, respectively. Correspondingly, $T_i$ and $T_f$ are the initial and the final turbidity and UV$_{254}$. The results has been only represented in the Fig. S1 and Fig. S2.
