Regulation of osteoblast development by Bcl-2-associated athanogene-1 (BAG-1)

Joanna Greenhough1, Emmanouil S. Papadakis2, Ramsey I. Cutress2, Paul A. Townsend3, Richard O. C. Oreffo1 & Rahul S. Tare1

BCL-2-associated athanogene-1 (BAG-1) is expressed by osteoblast-lineage cells; early embryonic lethality in Bag-1 null mice, however, has limited the investigation of BAG-1 function in osteoblast development. In the present study, bone morphogenetic protein-2/BMP-2-directed osteogenic differentiation of bone marrow stromal cells (BMSCs) of Bag-1+/− (heterozygous) female mice was decreased significantly. Genes crucial for osteogenic differentiation, bone matrix formation and mineralisation were expressed at significantly lower levels in cultures of Bag-1+/− BMSCs supplemented with BMP-2, while genes with roles in inhibition of BMP-2-directed osteoblastogenesis were significantly upregulated. 17-β-estradiol (E2) enhanced responsiveness of BMSCs of wild-type and Bag-1+/− mice to BMP-2, and promoted robust BMP-2-stimulated osteogenic differentiation of BMSCs. BAG-1 can modulate cellular responses to E2 by regulating the establishment of functional estrogen receptors (ERs), crucially, via its interaction with heat shock proteins (HSC70/HSP70). Inhibition of BAG-1 binding to HSC70 by the small-molecule chemical inhibitor, Thioflavin-S, and a short peptide derived from the C-terminal BAG domain, which mediates binding with the ATPase domain of HSC70, resulted in significant downregulation of E2/ER-facilitated BMP-2-directed osteogenic differentiation of BMSCs. These studies demonstrate for the first time the significance of BAG-1-mediated protein-protein interactions, specifically, BAG-1-regulated activation of ER by HSC70, in modulation of E2-facilitated BMP-2-directed osteoblast development.

Endochondral ossification, the process responsible for formation of majority of the bones that make up the skeleton, involves deposition of bone matrix by osteoblasts on intermediary cartilaginous primordia, which serve as scaffolds on which bones are subsequently built. Postnatally, endochondral ossification contributes to the longitudinal growth of bones and healing of bone fractures. Disruption of endochondral bone development results in a heterogeneous group of genetic diseases known as skeletal dysplasias that are characterised predominantly by short-limb dwarfism and, in certain chondrodysplasias, prenatal death1. Furthermore, dysregulation of early skeletal development is directly linked to diseases of the adult skeleton such as osteoporosis2,3. Thus, improved appreciation of skeletal development will enhance our understanding of musculoskeletal diseases and inform the development of novel strategies for replacement/regeneration of skeletal tissues.

The role of molecular chaperones and their co-chaperones in health and disease has attracted significant attention in recent years. Bcl-2-associated athanogene-1 (BAG-1), the founding member of the BAG-family of co-chaperones, is a multifunctional protein, capable of regulating cell proliferation, motility, differentiation and apoptosis4,5. Murine cells express two BAG-1 isoforms, BAG-1L (50 kDa) and BAG-1S (32 kDa), which are generated using alternate translation initiation sites in a single Bag-1 mRNA transcript6. During murine development, expression of Bag-1 mRNA is detected in several organs, with highest expression observed in cartilaginous tissues of the developing mouse embryo7. In long bones of postnatal mice, expression of BAG-1 is detected in articular and growth plate chondrocytes, in addition to osteoblast-lineage cells, namely bone marrow stromal cells (BMSCs), osteoblasts and osteocytes8,9. Remarkably, expression of

BAG-1 is upregulated in human osteoarthritic cartilage compared to normal articular cartilage, most likely in response to the disruption of chondrocyte homeostasis in osteoarthritis10. BAG-1 has been demonstrated to play important roles in the protection of mammalian chondrocytes against apoptosis induced by endoplasmic reticulum stress and heat shock, and in the regulation of expression of chondrogenic markers9,11. In contrast, to date, no studies have investigated the role of Bag-1 in osteoblast development. Gene knockout mouse models have proved pivotal in the analyses of bone development. Significant apoptosis in the embryonic liver and brain, along with defective haematopoiesis and neuronal cell differentiation have been identified as the major causes of death in Bag-1 null mice between E (embryonic day) 12.5 and E13.5 of gestation12. Early embryonic lethality in Bag-1 null mice has limited the investigation of the role of BAG-1 in bone development. This is primarily because vascular invasion of the calcified hypertrophic cartilage, resulting in the recruitment of osteoclasts and osteoblasts for the gradual replacement of the cartilaginous matrix with bone, occurs between E14.5 and E15.513. Mice heterozygous for the Bag-1 gene (i.e. containing one functional Bag-1 allele) are not embryonic lethal and survive into adulthood14, thereby allowing investigation of the effect of Bag-1 haploinsufficiency on osteoblast differentiation and bone development.

BAG-1 interacts with a diverse array of molecular targets, namely the 70-kDa heat shock chaperone proteins (HSC70/HSP70), RAF-1 kinase, components of the ubiquitylation/proteasome machinery and nuclear hormone receptors (NHRs), to regulate gene transcription and molecular signalling crucial for cell proliferation, differentiation and apoptosis15. Binding of BAG-1 to HSC70/HSP70 has now been acknowledged to be vital for most functions of BAG-1, including the effects of BAG-1 on NHRs16,17. The carboxy terminus BAG domain is composed of three alpha helices, which facilitate binding between BAG-1 and the amino terminal ATPase domain of HSC70/HSP7018. Helices 2 and 3 are involved in electrostatic interactions with the ATPase domain of HSC70/HSP70; helix 1 is not directly involved in the binding process and crucial for the molecular interactions that stabilise the overall structure of the BAG domain19. A very small region comprising of 8 amino acid residues in helix 2 of the BAG domain has been shown to be vital for binding of BAG-1 to HSC7020.

NHRs have been recognised as key regulators of cellular function and BAG-1 has been shown to regulate the functions of diverse NHRs, namely the glucocorticoid receptor, androgen receptor, estrogen receptors (ERs), retinoic acid receptor and vitamin D3 receptor11. NHRs (in their non-native states) interact with the central substrate/peptide-binding domain of the heat shock chaperone proteins and undergo a series of steps in the refolding/activation process to achieve correct conformations that facilitate binding of the NHRs to respective hormones22,23. The ATPase domain of HSC70/HSP70 regulates substrate binding through cycles of ATP binding and hydrolysis; substrates interact transiently with the ATP-bound form of HSC70/HSP70, while hydrolysis of ATP enables the substrates to bind the ADP-bound form of HSC70/HSP70 with high affinity24. Release of ADP and subsequent binding of ATP, referred to as nucleotide exchange, permits the release of the refolded substrates24.

BAG-1 interacts with the ATPase domain of HSC70/HSP70 and functions as a nucleotide exchange factor in the activation cycle25. Hence, by stimulating nucleotide exchange, BAG-1 regulates the dynamics of complex assembly crucial for the establishment and release of the functional NHRs prior to hormone binding. Thus, BAG-1, through its interaction with HSC70/HSP70, regulates the activation of NHRs, including ERs, and can play an important role in the modulation of cellular responses to steroid hormones, such as estrogen /-estradiol (E2). Moreover, after hormone binding, BAG-1 is able to influence receptor-mediated transcription of the nuclear hormone-responsive genes e.g. BAG-1 has been shown to interact with and stimulate the activity of both ERα and ERβ in the anti-BAG-1 antibody exhibited bands specific for BAG-1L (50 kDa) and BAG-1S (32 kDa) proteins (Fig. 1A). Immunoblotting and quantitation of the expression of BAG-1 isoforms in wild-type, heterozygous and null littermates (Supplementary Fig. 1B,C). BMSC cultures of 14-week-old wild-type and Bag-1−/− mice were harvested for the preparation of cell lysates for immunoblotting. Immunoblots probed with the anti-BAG-1 antibody exhibited bands specific for BAG-1L (50 kDa) and BAG-1S (32 kDa) proteins (Fig. 1A).
Figure 1. Proliferation and BMP-2-stimulated osteogenic differentiation of BMSCs of 14-week-old Bag-1+/+ and Bag-1+/− female mice. (A) Representative immunoblots demonstrating bands for BAG-1L, BAG-1S and β-Actin in day-28 cultures of BMSCs of Bag-1+/− and Bag-1+/+ female mice in basal medium. Densitometric quantification of the bands was performed to measure the expression of the BAG-1L and BAG-1S proteins, data was normalised to β-Actin and plotted in the form of bar graphs. (B) DNA concentrations of day-28 cultures of BMSCs of Bag-1+/+ and Bag-1+/− female mice in basal and osteogenic media. (C) Cell proliferation profiles over the course of 28-day osteogenic cultures of BMSCs of Bag-1+/+ and Bag-1+/− female mice. For statistical analyses, DNA concentrations were compared between days 1 and 14 of culture, and days 14 and 28 of culture. (D) ALPL specific activity and (E) osteocalcin concentration were measured in day-28 cultures of BMSCs of Bag-1+/+ and Bag-1+/− female mice in basal and osteogenic media. Results presented as mean ± SD; n = 3 cultures per group; ***P < 0.001, **P < 0.01, *P < 0.05.
and Supplementary Fig. 2A for female and male mice, respectively). Densitometric quantification of the bands was performed to measure the expression levels of the Bag-1L and Bag-1S proteins. Lower levels of Bag-1L and Bag-1S proteins were observed in BMSC cultures of Bag-1 heterozygous mice compared to wild-type mice (Fig. 1A and Supplementary Fig. 2A for female and male mice, respectively). The immunoblots also demonstrated intense bands for Bag-1S compared to Bag-1L in BMSC cultures of both wild-type and Bag-1 heterozygous mice, indicating higher expression of Bag-1S in comparison to Bag-1L in murine BMSCs.

Due to the direct correlation between cell number and DNA content, cell numbers in day-28 cultures of BMSCs in basal and osteogenic media were determined by measuring the cellular DNA concentration. In wild-type female mice, no differences in DNA concentration (and therefore cell number) were observed between day-28 BMSC cultures in basal and osteogenic media (Fig. 1B). In BMSC cultures of Bag-1 heterozygous female mice, DNA concentration of day-28 cultures in osteogenic medium was significantly higher than DNA concentration of day-28 cultures in basal medium (Fig. 1B). In both wild-type and Bag-1 heterozygous male mice, DNA concentrations of day-28 BMSC cultures were significantly lower in osteogenic conditions compared to basal conditions (Supplementary Fig. 2B). In osteogenic medium, BMSCs of wild-type female mice demonstrated negligible rates of proliferation over the 28-day culture period, while BMSCs of Bag-1 heterozygous female mice exhibited significantly higher rates of proliferation over 28 days (Fig. 1C). BMSCs of wild-type and heterozygous male mice proliferated at significantly higher rates during days 1 and 14 of culture, while proliferation of BMSCs in the two groups of male mice decreased significantly between days 14 and 28 of culture in osteogenic conditions (Supplementary Fig. 2C).

To examine the effect of haploinsufficiency of Bag-1 on the ability of BMSCs to differentiate into osteoblasts in response to BMP-2, 28-day cultures of BMSCs of wild-type and Bag-1 heterozygous mice were analysed for the expression of osteoblast-specific markers, namely Alkaline phosphatase, tissue non-specific isozyme (ALPL) and Osteocalcin. In wild-type female mice, specific activity of ALPL (Fig. 1D) and the concentration of osteocalcin (Fig. 1E) were significantly higher in day-28 BMSC cultures in osteogenic conditions compared to basal conditions. In Bag-1 heterozygous female mice, no significant differences in ALPL specific activity (Fig. 1D) and osteocalcin concentration (Fig. 1E) were observed between day-28 BMSC cultures in basal and osteogenic media. In contrast, in day-28 cultures of BMSCs of wild-type and Bag-1 heterozygous male mice, ALPL specific activity (Supplementary Fig. 2D) and osteocalcin concentration (Supplementary Fig. 2E) were significantly higher in osteogenic conditions compared to basal conditions. In comparison to day-28 osteogenic cultures of BMSCs of Bag-1 heterozygous female mice, day-28 osteogenic cultures of BMSCs of wild-type female mice exhibited higher number of colonies stained with Alizarin red (Supplementary Fig. 3).

Overall, a very low incidence of apoptosis was observed in day-28 BMSC cultures. No differences in cell apoptosis were observed between day-28 basal and osteogenic cultures of BMSCs of wild-type and Bag-1 heterozygous female (Supplementary Fig. 4A) and male (Supplementary Fig. 4B) mice.

**Differential expression of skeletal development genes between osteogenic cultures of BMSCs of wild-type and Bag-1 heterozygous mice.** The mouse osteogenesis RT² Profiler PCR arrays were employed to examine the differences in the expression of 84 genes crucial for skeletal development between day-28 osteogenic cultures of 14-week-old wild-type and Bag-1 heterozygous female mice. From the 84 genes constituting the array, 30 genes were differentially expressed between day-28 BMSC cultures of Bag-1 and Bag-1 heterozygous female mice in response to the osteogenic stimulus provided by BMP-2. Genes that were upregulated and downregulated in day-28 osteogenic cultures of Bag-1 heterozygous BMSCs relative to day-28 osteogenic cultures of Bag-1 BMSCs, along with the values for fold up/downregulation and statistical significance have been listed (Supplementary Fig. 5A). A volcano plot, constructed by plotting the negative log of the p-value on the y-axis and the fold change between the two conditions on the x-axis, enabled rapid identification of the 30 differentially expressed genes (Supplementary Fig. 5B; red circles represent upregulated genes and green circles represent downregulated genes).

Nine genes were significantly upregulated in day-28 osteogenic cultures of Bag-1 BMSCs compared to day-28 osteogenic cultures of Bag-1 BMSCs. The upregulated genes included Ahsg, Fgf2, Fn-1, which have important roles in regulation of osteogenic differentiation, Col11a1, Col4a1, Gdf-10, Mmp-8, Tnfsf-11 and Vcam-1, which have important functions in collagen fibril organisation, remodelling of the extracellular matrix, osteocalcogenesis and cell adhesion (Fig. 2 and Supplementary Fig. 5A). Expression levels of 21 genes were downregulated in day-28 osteogenic cultures of Bag-1 BMSCs, in comparison to day-28 osteogenic cultures of Bag-1 BMSCs, along with the values for fold up/downregulation and statistical significance have been listed (Supplementary Fig. 5A). A volcano plot, constructed by plotting the negative log of the p-value on the y-axis and the fold change between the two conditions on the x-axis, enabled rapid identification of the 30 differentially expressed genes (Supplementary Fig. 5B; red circles represent upregulated genes and green circles represent downregulated genes).

**Effect of estrogen on BMP-2-directed osteogenic differentiation of BMSCs.** The expression levels of genes encoding the estrogen receptors, namely ERα and ERβ, in day-28 cultures (in basal medium) of BMSCs of 14-week-old wild-type mice were compared to murine osteoblast-like MC3T3-E1 cells, which have been shown to express both receptor subtypes. Mouse BMSCs were found to express genes encoding the two ER isoforms; in comparison to MC3T3-E1 cells, expression of ERα was significantly lower in BMSCs, while expression of ERβ was significantly higher in BMSCs (Supplementary Fig. 6A). Osteogenic culture medium was supplemented with 17β-estradiol (E2) in concentrations of 10 nM, 100 nM, 10 nM and 100 nM to determine the optimal concentration of E2 capable of promoting BMP-2-directed osteogenic differentiation of BMSCs. Following culture for 28 days in basal, osteogenic and osteogenic media supplemented with different concentrations of E2, expression of Alpl was determined as an early marker of osteogenic differentiation of BMSCs. Expression of Alpl in wild-type BMSCs was significantly upregulated in response to BMP-2 in the osteogenic medium compared to basal culture conditions (Supplementary Fig. 6B). Moreover, in comparison to BMSCs cultured in osteogenic medium, statistically significant increase in the expression of Alpl was observed in BMSCs cultured for 28 days in osteogenic...
medium supplemented with 100 nM E2 (Supplementary Fig. 6B). Furthermore, culture of BMSCs of 14-week-old wild-type and Bag-1 heterozygous female mice for 28 days in osteogenic medium supplemented with 100 nM E2 resulted in significant increases in the expression of Bmpr2 (gene encoding BMP receptor Type II), compared to BMSC cultures in osteogenic medium (Supplementary Fig. 6C).

Analysis of inhibition of the interaction between BAG-1 and HSC70 by Thioflavin-S on E2/ER-facilitated BMP-2-directed osteogenic differentiation of BMSCs. Thioflavin-S, a small-molecule chemical inhibitor of the interaction between BAG-1 and heat shock proteins, was used to investigate the functional significance of BAG-1-mediated protein-protein interactions, specifically, BAG-1-regulated activation of ER by HSC70, in E2-facilitated BMP-2-directed osteogenic differentiation of BMSCs. BMSCs of 14-week-old Bag-1+/+ and Bag-1−/− female mice were cultured for 28 days in basal medium, osteogenic medium, osteogenic medium supplemented with 100 nM E2 and osteogenic medium supplemented with 100 nM E2 and 5 μM Thioflavin-S. Day-28 BMSC cultures were harvested for the analyses of expression of osteogenic genes, namely Runx-2, Osterix, Apl and Osteocalcin, estimation of ALPL specific activity and quantitation of DNA concentration.

Compared to cultures in basal medium, day-28 cultures of BMSCs of Bag-1+/+ mice exhibited significantly increased expression of osteogenic genes (Fig. 3A) and significantly higher specific activity of ALPL (Fig. 3B) in osteogenic and E2-supplemented osteogenic media. Moreover, the osteogenic response was higher in day-28 cultures of BMSCs of Bag-1+/+ mice in osteogenic medium supplemented with E2, in comparison to day-28 cultures in osteogenic medium. BMSCs of Bag-1−/− female mice did not exhibit robust osteogenic differentiation in day-28 cultures in osteogenic medium compared to cultures in basal medium (Fig. 4A,B). This observation was in keeping with our previous findings, which demonstrated decreased osteogenic response to BMP-2 by BMSCs of Bag-1−/− female mice (Fig. 1D,E). Remarkably, expression of osteogenic genes (Fig. 4A) and specific activity of ALPL (Fig. 4B) were significantly upregulated in day-28 BMSC cultures of Bag-1−/− female mice in osteogenic medium supplemented with E2, compared to day-28 cultures of Bag-1+/− BMSCs in osteogenic and basal media. In comparison to the robust osteogenic differentiation of Bag-1+/+ and Bag-1−/− BMSCs in day-28 cultures in E2-supplemented osteogenic medium, expression of osteogenic genes (Figs 3A and 4A) and specific activity of
Figure 3. Effect of Thioflavin-S (ThS), a small-molecule chemical inhibitor of the interaction between BAG-1 and HSC70, on E2/ER-facilitated BMP-2-directed osteogenic differentiation of BMSCs of 14-week-old Bag-1+/+ female mice. (A) Expression levels of osteogenic genes, namely Runx-2, Osterix, Alpl and Osteocalcin, were measured in day-28 cultures of BMSCs in basal, osteogenic, osteogenic + E2, osteogenic + E2 + Thioflavin-S media. Fold changes ($2^{-\Delta\Delta C_T}$) in relative mRNA transcript levels were normalised to the endogenous reference ($\beta$-Actin) and plotted as bar graphs. The range of gene expression was indicated by $2^{-\Delta\Delta C_T \pm SD}$ and $2^{-\Delta\Delta C_T - SD}$, where SD: standard deviation of the $\Delta\Delta C_T/\Delta C_T$ value. (B) Specific activity of ALPL (presented as mean ± SD) was measured in day-28 cultures of BMSCs in basal, osteogenic, osteogenic + E2, osteogenic + E2 + Thioflavin-S media; n = 3 cultures per group; ***P < 0.001.
Figure 4. Effect of Thioflavin-S (ThS), a small-molecule chemical inhibitor of the interaction between BAG-1 and HSC70, on E2/ER-facilitated BMP-2-directed osteogenic differentiation of BMSCs of 14-week-old Bag-1+/− female mice. (A) Expression levels of osteogenic genes, namely Runx-2, Osterix, Alpl and Osteocalcin, were measured in day-28 cultures of BMSCs in basal, osteogenic, osteogenic + E2, osteogenic + E2 + Thioflavin-S media. Fold changes (2−ΔΔCT) in relative mRNA transcript levels were normalised to the endogenous reference (β-Actin) and plotted as bar graphs. The range of gene expression was indicated by 2−(ΔΔCT+SD) and 2−(ΔΔCT−SD), where SD: standard deviation of the ΔΔCT value. (B) Specific activity of ALPL (presented as mean ± SD) was measured in day-28 cultures of BMSCs in basal, osteogenic, osteogenic + E2, osteogenic + E2 + Thioflavin-S media; n = 3 cultures per group; ***P < 0.001.
ALPL (Figs 3B and 4B) were significantly decreased in day-28 cultures of BMSCs of Bag-1+/− and Bag-1+/+ mice in E2-containing osteogenic medium supplemented with Thioflavin-S.

**Effect of inhibition of binding of BAG-1 to HSC70 by the BAG domain-derived short peptide on E2/ER-facilitated BMP-2-directed osteogenic differentiation of BMSCs.** BAG-1 binds to the ATPase domain of HSC70 via a very small region comprising of 8 amino acid residues in helix 2 of the C-terminal BAG domain. A short peptide, H2-Penetratin, containing the 8 amino acid binding core of helix 2 of the BAG domain coupled via a peptide bond to Penetratin, was synthesized to inhibit the binding of BAG-1 to HSC70. A mutant peptide, H2mutant-Penetratin, with alanine substitutions for arginine residues at positions 205 and 206 that represented the ‘hot-spot’ on the interaction surface between BAG-1 and HSC70, was also synthesized as the control peptide. BMSCs of 14-week-old Bag-1+/+ and Bag-1+/− female mice were cultured for 28 days in basal medium, osteogenic medium supplemented with 100 nM E2 and osteogenic medium supplemented with 100 nM E2 in addition to either 10 μM H2-Penetratin or 10 μM H2mutant-Penetratin. Day-28 BMSC cultures were harvested for the analyses of expression of osteogenic genes, namely Runx-2, Osterix, Alpl and Osteocalcin, and estimation of ALPL specific activity, osteocalcin and DNA concentrations.

In comparison to day-28 cultures in basal medium, significant increases in the expression of osteogenic genes (Figs 5A and 6A), specific activity of ALPL (Figs 5B and 6B) and osteocalcin concentration (Figs 5C and 6C) were observed in day-28 cultures of BMSCs of Bag-1+/+ and Bag-1+/− mice in osteogenic medium supplemented with E2. Significant decreases in the expression of osteogenic genes (Figs 5A and 6A), specific activity of ALPL (Figs 5B and 6B) and osteocalcin concentration (Figs 5C and 6C) were observed in day-28 cultures of BMSCs of Bag-1+/+ and Bag-1+/− mice in osteogenic medium supplemented with E2 and H2-Penetratin, compared to day-28 cultures in osteogenic medium supplemented with E2. In contrast, H2mutant-Penetratin had no effect on E2/ER-facilitated BMP-2-directed osteogenic responses of BMSCs of Bag-1+/+ and Bag-1+/− mice. This was demonstrated by no differences in the expression of osteogenic genes (Figs 5A and 6A), specific activity of ALPL (Figs 5B and 6B) and osteocalcin concentration (Figs 5C and 6C) between day-28 BMSC cultures in E2-supplemented osteogenic medium and osteogenic medium supplemented with E2 and H2mutant-Penetratin. Moreover, expression of osteogenic genes (Figs 5A and 6A), specific activity of ALPL (Figs 5B and 6B) and osteocalcin concentration (Figs 5C and 6C) were significantly higher in day-28 BMSC cultures in osteogenic medium supplemented with E2 and H2mutant-Penetratin, compared to day-28 cultures in osteogenic medium supplemented with E2 and H2-Penetratin.

**Effects of Thioflavin-S and the BAG-domain-derived short peptides on BMSC viability and proliferation.** No differences in cell number/DNA content between day-28 cultures of BMSCs (of both Bag-1+/+ and Bag-1+/− mice) in E2-supplemented osteogenic medium and osteogenic medium supplemented with E2 and Thioflavin-S confirmed that Thioflavin-S was not toxic to the BMSCs (Fig. 7A). Similarly, BMSC viability and proliferation were unaffected by the short peptides, namely H2-Penetratin and H2mutant-Penetratin, as demonstrated by no differences in cell number/DNA concentrations between day-28 cultures of BMSCs of both Bag-1+/+ and Bag-1+/− mice in E2-supplemented osteogenic medium and osteogenic medium supplemented with E2 and the short peptides (Fig. 7B).

**Discussion**

The present study has highlighted the significance of BAG-1-regulated activation of ER by HSC70 in the modulation of E2-facilitated BMP-2-stimulated osteogenic differentiation of murine BMSCs. This work has therefore demonstrated for the first time the importance of BAG-1-mediated protein-protein interactions in the regulation of osteoblast development. While both BAG-1 isoforms were expressed by murine BMSCs, expression of BAG-1S was observed to be higher than BAG-1L. This finding is in keeping with observations made by previous studies that BAG-1S is the major BAG-1 isoform in rodent cells. To elucidate the causes of decreased BMP-2-directed osteogenic differentiation of BMSCs of Bag-1+/− female mice, differences in the expression of an array of genes crucial for skeletal development were analysed between osteogenic cultures of BMSCs of Bag-1+/− and Bag-1+/+ female mice. Increased expression of Ahsg (Fetuin), Fgf2 (Fibroblast growth factor-2) and Fn1 (Fibronectin) in osteogenic cultures of BMSCs of Bag-1+/− female mice contributed, in part, to the lower osteogenic response of the cells to BMP-2 and the increased rate of cell proliferation. Fetuin acts as an inhibitor of osteogenesis in rodent BMSC cultures due to its high affinity for the extracellular matrix during cell proliferation and early differentiation, while synthesis of fibronectin is dramatically reduced with cell maturation. It is therefore possible that significant upregulation of Fn1 expression in osteogenic cultures of BMSCs of Bag-1+/− female mice, in comparison to osteogenic cultures of BMSCs of Bag-1+/+ female mice, reflects the highly proliferative/early differentiation state of the cells.

The important roles of BMP-2, BMP-4 and BMP-7 in the induction of differentiation of osteoblast lineage cells have been widely recognised. Downregulation of expression of the osteoinductive BMPs could have contributed to decreased osteogenic differentiation of Bag-1+/− BMSCs in comparison to Bag-1+/+ BMSCs. Additionally, expression levels of SP7 (encoding the transcription factor Osterix), crucial for differentiation of preosteoblasts into functional osteoblasts, were significantly downregulated in osteogenic cultures of Bag-1+/+ BMSCs.
Figure 5. Effect of inhibition of BAG-1 binding to HSC70 by the C-terminal BAG domain-derived short peptide (H2-Penetratin) on E2/ER-facilitated BMP-2-directed osteogenic differentiation of BMSCs of 14-week-old Bag-1+/+ female mice. (A) Expression levels of osteogenic genes, namely *Runx-2*, *Osterix*, *Alpl* and *Osteocalcin*, were measured in day-28 cultures of BMSCs in basal, osteogenic + E2, osteogenic + E2 + H2-Penetratin, osteogenic + E2 + H2mutant-Penetratin media. Fold changes ($2^{-\Delta\Delta C_T}$) in relative mRNA transcript levels were normalised to the endogenous reference (*β*-Actin) and plotted as bar graphs. The range of gene expression was indicated by $2^{-\Delta\Delta C_T \pm SD}$ and $2^{-\Delta\Delta C_T - SD}$, where SD: standard deviation of the $\Delta\Delta C_T$ value. (B) Specific activity of ALPL and (C) concentration of osteocalcin were determined in day-28 cultures of BMSCs in basal, osteogenic + E2, osteogenic + E2 + H2-Penetratin, osteogenic + E2 + H2mutant-Penetratin media. Results for ALPL specific activity and osteocalcin concentration presented as mean ± SD; n = 3 cultures per group; ***P < 0.001.
Figure 6. Effect of inhibition of BAG-1 binding to HSC70 by the C-terminal BAG domain-derived short peptide (H2-Penetratin) on E2/ER-facilitated BMP-2-directed osteogenic differentiation of BMSCs of 14-week-old Bag-1+/− female mice. (A) Expression levels of osteogenic genes, namely Runx-2, Osterix, Alpl and Osteocalcin, were measured in day-28 cultures of BMSCs in basal, osteogenic + E2, osteogenic + E2 + H2-Penetratin, osteogenic + E2 + H2mutant-Penetratin media. Fold changes \(2^{-\Delta\Delta C_{T}}\) in relative mRNA transcript levels were normalised to the endogenous reference (β-Actin) and plotted as bar graphs. The range of gene expression was indicated by \(2^{-\Delta\Delta C_{T}}\pm SD\) and \(2^{-\Delta\Delta C_{T}}-SD\), where SD: standard deviation of the \(\Delta\Delta C_{T}\) value. (B) Specific activity of ALPL and (C) concentration of osteocalcin were determined in day-28 cultures of BMSCs in basal, osteogenic + E2, osteogenic + E2 + H2-Penetratin, osteogenic + E2 + H2mutant-Penetratin media. which has a regulatory role in bone mineral maturation45,46 and the osteoclastogenesis of the monocytic osteoclast can be established, as part of the future work, to determine whether osteoclastogenesis of the monocytic osteoclast is decreased in response to increased expression of RANKL by the BMSCs.

Moreover, downregulation of expression of Col1a1, Col1a2, Col5a1, Serpinh1, Alpl, Spp1, Bglap and Phex in osteogenic cultures of BMSCs of Bag-1+/− female mice contributed to decreased synthesis of the bone matrix and its mineralisation. Type I collagen is the most abundant collagen in bone matrix, while Type V collagen is essential for the formation of normal Type I collagen fibrils due to the critical role of Type V collagen in early fibril initiation, determination of fibril structure and matrix organisation41. The collagen-specific molecular chaperone, Serpinh-1/HSP47, is located in the endoplasmic reticulum and plays an important role in collagen biosynthesis42. Matrix mineralisation is regulated by ALPL, an enzyme with a pivotal role in mineralisation43, Osteopontin (Spp1), which has key roles in mineral-binding and regulation of crystal growth44, Osteocalcin (Bglap), an osteoblast-specific protein characterised by the presence of γ-carboxyglutamatic acid (Gla) residues, which has a regulatory role in bone mineral maturation45,46 and Phex (Phosphate-regulating gene with homologies to endopeptidases on the X chromosome), encoding a protease responsible for the degradation and clearance of mineralisation-inhibiting ASARM (acidic serine and aspartate-rich motif) peptides that are derived from a group of extracellular matrix SIBLING (small integrin-binding ligand N-linked glycoprotein) proteins including MEPE (matrix extracellular phosphoglycoprotein) and osteopontin47.

Interestingly, expression of Tnsf11 was upregulated almost 4-fold in BMSC cultures of Bag-1+/− female mice compared to BMSC cultures of Bag-1+/+ female mice. The cytokine TNFSF11 (Tumor necrosis factor (ligand) superfamily, member 11 or RANKL: Receptor activator of nuclear factor kappa-B ligand), alongside macrophage colony stimulating factor (M-CSF), is essential for osteoclast formation48. Interaction of RANKL, expressed primarily on the surface of stromal cells and osteoblasts in the bone marrow, with RANK, expressed on the surface of blood-derived mononuclear osteoclast precursors, stimulates osteoclastogenesis49. Co-cultures of cells harvested from day-28 osteogenic cultures of BMSCs of Bag-1+/− female mice with blood-derived mononuclear cells will be established, as part of the future work, to determine whether osteoclastogenesis of the monocytic osteoclast precursors is enhanced in response to increased expression of RANKL by the BMSCs.

Bag-1 haploinsufficiency did not affect the osteogenic response of BMSCs of Bag-1 heterozygous male mice to BMP-2; this highlighted the need to understand the role of interacting factors capable of modulating gender differences in BMP-2-directed osteogenic differentiation of BMSCs of Bag-1+/− mice. Estrogen, the primary female sex hormone, binds to estrogen receptors, ligand-activated enhancer proteins that are members of the NHR superfamily, and is functionally involved in the process of BMP-directed osteoblast differentiation of osteoprogenitor cells via upregulation of Bmpr2 expression and Smad 1/5/8 phosphorylation28. The present study has demonstrated the expression of ERα and ERβ by primary murine BMSCs and significant upregulation of Bmpr2 expression in BMP-2-treated cultures of BMSCs supplemented with 100 nM E2. Co-treatment of mouse BMSCs with BMP-2 and E2 has been shown to enhance osteogenic lineage commitment of the multipotent cell population at the expense of adipogenic differentiation and the modulation of BMSC lineage shift towards the osteoblast phenotype by E2 occurred in an ER-specific manner, but without ER subtype specificity27. Thus, E2 increased the responsiveness of ER-expressing BMSCs of Bag-1+/− and Bag-1−/− female mice to BMP-2 through upregulation of the expression of Bmpr2 and facilitated robust osteogenesis by enhancing the commitment of the BMSC population to differentiate into the osteoblast lineage.

Thioflavin S functions as a small molecule chemical inhibitor of the interaction between BAG-1 and HSC70, since the binding site for the compound lies within helix 2 of the BAG domain; alternatively, it is possible that Thioflavin S may bind elsewhere within BAG-1 and elicit a conformational change in the BAG domain, leading to the loss of multiple interaction partners, including HSC7029. Through its interaction with HSC70, BAG-1 can...
regulate the activation of NHRs, including ERs, and play an important role in the modulation of cellular responses to steroid hormones, such as E2. In the present study, Thioflavin S disrupted the binding between HSC70 and Bag-1 in BMSC cultures supplemented with BMP-2 and E2, resulting in the downregulation of E2-facilitated osteogenic differentiation of BMSCs. Thioflavin S therefore served as a useful tool to elucidate the functional significance of Bag-1-regulated activation of ER by HSC70 in E2-facilitated BMP-2-directed osteogenic differentiation of BMSCs. However, Thioflavin S/NSC71948 is a mixture of components arising from the methylation and sulfonation of primulin base, the selectivity profile of which is not fully characterised and thus, the likelihood of off-target effects cannot be ruled out.

Hence, to improve selectivity/specificity, a short peptide, H2-Penetratin, containing the 8 amino acid binding core of helix 2, coupled via a peptide bond at its C-terminus to Penetratin, a fragment of the Antennapedia protein that enhances cellular uptake, was used to inhibit the binding between Bag-1 and HSC70 in BMSC cultures supplemented with BMP-2 and E2. The H2-Penetratin peptide has been demonstrated to bind the ATPase domain of HSC70 and exert its effects, such as growth inhibition, in human breast cancer cells by preventing the interaction between Bag-1 and HSC70. Similarly, in our study, inhibition of binding of Bag-1 to HSC70 by H2-Penetratin resulted in significant downregulation of E2/ER-facilitated BMP-2-directed osteogenic responses of BMSCs of both Bag-1+/− and Bag-1+/− mice. The mutant peptide, with alanine substitutions for arginine residues at positions 205 and 206 representing the ‘hot-spot’ on the interaction surface between Bag-1 and HSC70, was significantly less effective in downregulating the osteogenic responses of the BMSCs, thereby confirming the specificity of the H2-Penetratin peptide to disrupt the interaction between Bag-1 and HSC70 in BMSCs and cause downregulation of E2/ER-facilitated BMP-2-directed osteogenic differentiation.

Since no differences were observed in cell number/DNA content between day-28 cultures of BMSCs in osteogenic medium supplemented with E2 and osteogenic medium supplemented with E2, Thioflavin-S or the Bag domain-derived short peptides, decreased E2/ER-facilitated BMP-2-directed osteogenic responses of BMSCs in presence of Thioflavin S and the H2-Penetratin peptide were not due to compromised cell viability. It is, however, important to note that, in addition to HSC70 binding, the Bag domain facilitates binding of Bag-1 to RAF-1 through helices 1 and 2. As the binding sites for HSC70 and RAF-1 overlap, which can result in competitive binding, more specific mutations in the Bag domain binding region of the Bag domain will need to be created as part of the future work to gain valuable information regarding the significance of the independent role of the interaction of HSC70 with Bag-1 in the regulation of E2/ER-facilitated BMP-2-directed osteogenic differentiation of BMSCs.

In summary, the present study has demonstrated that deletion of one functional Bag-1 allele decreased the potential of BMSCs of Bag-1+/− female mice to differentiate into osteoblasts in response to BMP-2. Although there are many mechanisms and targets of Bag-1 function, the ability of Bag-1 to regulate the activation of NHRs, critically, through its interaction with the HSC70/HSP70 chaperone proteins, has now been accepted as one of the key mechanisms of regulation of cellular functions by Bag-1. By highlighting the significance of the interaction between Bag-1 and HSC70 in the modulation of E2/ER-facilitated BMP-2-directed osteogenic differentiation of BMSCs, our study has provided valuable insight into the role of Bag-1-mediated protein-protein interactions in the regulation of osteoblast development. Generation of conditional knockout mice in which the Bag-1 gene is deleted from osteoblast-lineage cells would aid comprehensive investigation of the role of Bag-1 in bone development.

Materials and Methods
Chemicals and reagents were purchased from Invitrogen (Paisley, UK) and Sigma-Aldrich (Gillingham, UK) unless specified.

Bag-1+/− mice. The protocol for targeted inactivation of the mouse Bag-1 locus and the PCR strategy for genotyping Bag-1−/−, Bag-1−/+ and Bag-1+/− mice have been described previously. The Bag-1−/− mice were provided by Prof. Stefan Wiese (Ruhr University Bochum, Germany) and bred in the Biomedical Research Facility, University of Southampton. The mice were housed in appropriate environments maintained at 21 °C ± 2 °C and 55% ± 10% humidity with 15–20 room air changes per hour and 12-h/12-h light/dark cycles. The mice had free access to water and were fed ad libitum. All animal experimentation was performed under licence (Ref. No. 70/6422) granted by the Home Office (UK) in accordance with the Animals (Scientific Procedures) Act 1986.

Health and Safety risk assessments were performed for all experimental protocols and the protocols were approved by the Research Governance Office, University of Southampton.

Cultures of mouse BMSCs. Femora and tibiae were dissected from 14-week-old Bag-1+/− and Bag-1+/+ mice for isolation of BMSCs using an established protocol. For each experiment, BMSCs were pooled from the femora and tibiae of 3–4 mice. The cells were plated in 6-well plates at a seeding density of 500,000 cells/cm². After 6 days of culture in basal medium (phenol red-free αMEM containing 1% penicillin/streptomycin, 10% charcoal stripped fetal calf serum/FCS and 50 μM 3-mercaptopethanol), non-adherent red blood cells were removed by washing the cultures using sterile PBS and tissue culture plastic-adherent stromal cells were cultured for further 22 days in basal medium, osteogenic medium (basal medium supplemented with 100 ng/ml rhBMP-2, 100 μM ascorbate-2-phosphate), osteogenic medium supplemented with E2 (10 μM, 1 nM, 100 nM), osteogenic medium supplemented with E2 (100 nM) and Thioflavin-S (5 μM), osteogenic medium supplemented with E2 (100 nM) and H2-Penetratin/H2mutant-Penetratin (10 μM). As Thioflavin-S was reconstituted in dimethyl sulfoxide (DMSO) and the effective concentration of DMSO in the culture medium containing 5 μM Thioflavin-S was 0.03%, osteogenic medium containing 100 nM E2 was supplemented with 0.05% DMSO in the experiments investigating the effect of Thioflavin-S. Cultures were harvested for detection of apoptosis, biochemical and molecular biology investigations.
The peptides were ordered from ProteoGenix SAS (Schiltigheim, France) and reconstituted in ultrapure water. H2-Penetratin, CKLDRAVKATIERQIKIWQFPQRRMWWK, contained the 8 amino acid binding core of helix 2 (sequence in italics), coupled via a peptide bond at its C-terminus to Penetratin (sequence in bold), a cell permeable fragment of the Antennapedia protein that enhances delivery of cell penetrating peptides. H2mutant-Penetratin, AAIKDAAVKATIERQIKIWQFPQRRMWWK, was characterised by alanine (A) substitutions, particularly for arginine (R) residues at positions 205 and 206 (underlined) that represented the 'hot-spot' on the interaction surface between BAG-1 and HSC70.

**Alizarin red staining.** Day-28 cultures of BMSCs were fixed using 4% paraformaldehyde. Following a PBS wash, Alizarin red solution (40 mM, pH 4.1–4.3) was added to wells and the plates were incubated at room temperature for 20 minutes on the shaker. Cultures were then washed numerous times with fresh ultrapure water to remove the excess stain. Colonies stained with Alizarin red were observed using the Zeiss Axiovert 200 inverted fluorescence microscope (Carl Zeiss, Cambridge, UK) and imaged using a CCD camera with Axiosvision imaging software.

**Detection of cell apoptosis.** Cell cultures were fixed using 4% paraformaldehyde and terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) was performed using the Apoptosis Detection System (Promega, Southampton, UK) according to the manufacturer's instructions. Positive controls for detection of DNA fragmentation were prepared by treating BMSCs with DNase-1. Nuclei were labelled with Propidium iodide, staining was observed using the Zeiss Axiovert 200 inverted fluorescence microscope and imaged using a CCD camera with Axiosvision imaging software. To quantify the results of apoptosis, Propidium iodide-stained nucleated cells and TUNEL-positive apoptotic cells were counted in five different fields of view, and the number of apoptotic cells was calculated as percentage of the total cell number.

**Biochemical investigations.** Cells harvested from the cultures were lysed in 0.05% Triton-X and the cell lysates were used for biochemical analyses, namely DNA quantification, estimation of ALPL specific activity and osteocalcin concentration.

**DNA quantification.** The fluorescent PicoGreen® double-stranded DNA quantification reagent was used for DNA quantification as described previously. The fluorescence was measured using the FLX-800 microplate fluorescence reader (excitation wavelength of 485 nm, emission wavelength of 530 nm) equipped with the BioTek KC4 KinetiCalc for Windows software (BioTek, Swindon, UK). The DNA content of the sample was quantified by comparison of the sample fluorescence to the fluorescence of a set of standards that were included in every sample run.

**Estimation of ALPL specific activity.** ALPL specific activity was measured as previously described. In brief, the method involved the conversion of p-nitrophenyl phosphate by ALP to p-nitrophenol (pNP) and inorganic phosphate under alkaline conditions. The absorbance was measured at 410 nm using ELX-800 universal microplate reader equipped with the BioTek KC4 KinetiCalc for Windows software (BioTek, Swindon, UK). The concentration of pNP was quantified by comparison of the sample absorbance to the absorbance of a set of pNP standards that were included in every sample run. ALPL specific activity was calculated and expressed as nmol pNP/ng DNA/hr.

**Quantification of osteocalcin concentration.** Concentration of osteocalcin was measured using the mouse osteocalcin ELIA kit (Bioquote Ltd., York, UK), a sandwich ELISA assay, following manufacturer's instructions. The absorbance was measured at 450 nm using the microplate reader and concentration of osteocalcin was quantified by comparison of the sample absorbance to the absorbance of a set of osteocalcin standards that were included in every sample run. The values were expressed as ng osteocalcin/ng DNA.

**Real-time quantitative PCR.** Total RNA was isolated using the RNeasy kit (Qiagen, Manchester, UK) following manufacturer's instructions. The RNA samples were treated with DNase-1 reagent and reverse-transcribed using the SuperScript® VILO™ kit. Real-time quantitative PCR assays were performed using the 7500 Real-Time PCR system (Applied Biosystems, Paisley, UK) for analysing the expression of target genes of interest. The absorbance was measured at 450 nm using the microplate reader and concentration of osteocalcin was quantified by comparison of the sample absorbance to the absorbance of a set of osteocalcin standards that were included in every sample run. The values were expressed as ng osteocalcin/ng DNA.

The range of gene expression was indicated by $2^{-\Delta\Delta C_T}$ and $2^{-(\Delta\Delta C_T - SD)}$, where SD: standard deviation of the $\Delta\Delta C_T$ value. Statistical analyses were performed at the level of $\Delta C_T$ in order to exclude potential bias due to averaging of data transformed through the $2^{-\Delta\Delta C_T}$ equation.
PCR array. The mouse osteogenesis PCR array (RT² Profiler PCR Array—Qiagen, Manchester, UK) was used according to the manufacturer's protocol to analyse the expression of 84 genes related to skeletal development. The PCR arrays were performed in triplicate using the 7500 Real-Time PCR system and results were analysed using RT² Profiler PCR array data analysis version 3.5. Five housekeeping genes, namely β-Actin, β-2-Microglobulin, Glyceraldehyde-3-phosphate dehydrogenase, β-Glucuronidase, α-Heat shock protein 90, were included in the array for normalisation of data. The threshold for the fold–change in gene expression was set at 2 and the significance of the difference in gene expression was calculated with the P-value set at 0.05.

Immunoblotting. Cell lysates were prepared using the radioimmunoprecipitation assay (RIPA) buffer and protein concentrations in the lysates were determined using the Pierce™ BCA protein assay kit (ThermoFisher Scientific, Loughborough, UK). The samples (12 μg protein per well in 15 μl loading volume) were resolved in 10% SDS bisacrylamide gels and electroblotted onto nitrocellulose membranes. The membranes were probed with rabbit anti-BAG-1/C-16 (Santa Cruz Biotechnology, Heidelberg, Germany) and rabbit anti–β-actin primary antibodies, used at 1:200 and 1:3000 dilutions, respectively, followed by the goat anti-rabbit IgG–Peroxidase conjugate secondary antibody (1:5000 dilution). Immobilon Western Chemiluminescent HRP Substrate (Merck Millipore UK Ltd, Watford, UK) was used for signal detection. For digital acquisition of the chemiluminescent signals, blots were imaged using the VersaDoc Imaging System (Bio-Rad Laboratories Ltd., Hemel Hempstead, UK) and data were analysed using Quantity One® 1-D analysis software. Expression of the BAG-1L and BAG-1S proteins were imaged using the VersaDoc Imaging System (Bio-Rad Laboratories Ltd., Hemel Hempstead, UK) and data were analysed using Quantity One® 1-D analysis software. Expression of the BAG-1L and BAG-1S proteins were normalised to β-actin.

Statistical analyses. Statistical analyses were performed using the GraphPad Prism software (GraphPad Software Inc., San Diego, USA). The data is representative of a minimum of three independent experimental repeats and the results are presented as mean ± SD. Depending upon the experimental design, differences between the groups were analysed using paired t-test, unpaired t-test (two-tailed P value) and one-way analysis of variance (ANOVA) with Tukey's post-hoc test. Results were deemed significant if the probability of occurrence by random chance alone was less than 5% (i.e. P < 0.05).
