Green synthesis of multifunctional silver and gold nanoparticles from the oriental herbal adaptogen: Siberian ginseng

Abstract: Pharmacologically active stem of the oriental herbal adaptogen, Siberian ginseng, was employed for the ecofriendly synthesis of Siberian ginseng silver nanoparticles (Sg-AgNPs) and Siberian ginseng gold nanoparticles (Sg-AuNPs). First, for metabolic characterization of the sample, liquid chromatography-tandem mass spectrometry analysis (indicated the presence of eleutherosides A and E), total phenol content, and total reducing sugar were analyzed. Second, the water extract of the sample mediated the biological synthesis of both Sg-AgNPs and Sg-AuNPs that were crystalline face-centered cubical structures with a Z-average hydrodynamic diameter of 126 and 189 nm, respectively. Moreover, Fourier transform infrared analysis indicated that proteins and aromatic hydrocarbons play a key role in the formation and stabilization of Sg-AgNPs, whereas phenolic compounds accounted for the synthesis and stability of Sg-AuNPs. 3-(4,5-Dimethyl-2-thiazolyl)-2,5-diphenyl-2H tetrazolium bromide (MTT) assay determined that Sg-AgNPs conferred strong cytotoxicity against MCF7 (human breast cancer cell line) and was only slightly toxic to HaCaT (human keratinocyte cell line) at 10 µg/mL. However, Sg-AuNPs did not display cytotoxic effects against both of the cell lines. The disc diffusion assay indicated a dose-dependent increase in the zone of inhibition of Staphylococcus aureus (ATCC 6538), Bacillus anthracis (NCTC 10340), Vibrio parahaemolyticus (ATCC 33844), and Escherichia coli (BL21) treated with Sg-AgNPs, whereas Sg-AuNPs did not show inhibitory activity. In addition, the 2,2-diphenyl-1-picrylhydrazyl assay demonstrated that both Sg-AgNPs and Sg-AuNPs possess strong antioxidant activity. To the best of our knowledge, this is the first report unraveling the potential of Eleutherococcus senticosus for silver and gold nanoparticle synthesis along with its biological applications, which in turn would promote widespread usage of the endemic Siberian ginseng.

Keywords: Siberian ginseng, eleutheroside E, eleutheroside A, green synthesis, cytotoxicity, antibacterial activity, antioxidant efficacy

Introduction

Nanobiotechnology is a blend of nanotechnology and biotechnology that chiefly involves the application of nanoparticles to shed light on the development of novel strategies used to address biological issues. Nanoparticles play a pivotal role in cancer therapy, drug delivery, and also in other biomedical applications. Among them, metal and polymer nanoparticles are commonly analyzed for application in the medicinal field. In addition, metal nanoparticles have inherent biological activities and are compatible for therapeutic applications. Therefore, there is an imperative need to establish a methodology for their large-scale synthesis. Usually, their mass production is performed through various physical and chemical methods, which...
often results in the accumulation of toxic chemicals in the environment, thereby posing a threat to human, animal, and plant health.\(^7\) Green synthesis is one of the best alternatives owing to its ecofriendly nature. In this regard, plant and microbe-mediated synthesis has been attempted in the past, and the plant system was found to be much faster than using a microbial system. Moreover, the green synthesized nanoparticles also exhibit strong cytotoxic, antimicrobial, and antioxidant activities.\(^2,8,9\)

Among medicinal plant sources, Siberian ginseng (Eleutherococcus senticosus) is widely used in oriental medicine. It belongs to the Araliaceae family and is predominantly found in Russia, People’s Republic of China, Korea, and Japan. It is considered to be an adaptogen and is chiefly exploited for strengthening the spleen and kidney.\(^10,11\) Eleutherosides, the major bioactive compounds found in E. senticosus, are phenylpropanoids, lignin glycosides that occur abundantly in the roots and stems.\(^12\) E. senticosus has been proven to possess anticancer,\(^13\) antioxidant, and antimicrobial activities.\(^13–15\)

We hypothesize that silver and gold nanoparticles from E. senticosus would exhibit strong biological activities, similar to that of the precursors. In addition, E. senticosus is a perennial plant and is endemic to certain geographical locations. Therefore, the option of utilizing the nanoparticles synthesized from Siberian ginseng would enable its widespread usage in the medicinal field. Initially, liquid chromatography-tandem mass spectrometry (LC-MS/MS) analysis of the ethanolic extract indicated the presence of eleutherosides A and E. Folin–Ciocalteu (F-C) analysis and a 3,5-dinitrosalicylic acid (DNS) assay were performed to determine the quantity of total phenolics and the total reducing sugars. Following that, the water extract of the sample was used for the synthesis of Siberian ginseng silver nanoparticles (Sg-AgNPs) and Siberian ginseng gold nanoparticles (Sg-AuNPs). Physicochemical techniques, namely ultraviolet-visible (UV-Vis) spectrophotometry, field emission transmission electron microscopy (FE-TEM), energy dispersive X-ray spectroscopy (EDX), selected area electron diffraction pattern, dynamic light scattering particle size analysis, X-ray diffraction analysis, and Fourier transform infrared analysis (FTIR), aided in the elucidation of their morphological and chemical nature. Finally, the synthesized nanoparticles were investigated for their cytotoxic potential (against MCF7, a breast cancer cell line, and HaCaT, a human keratinocyte cell line), antibacterial (against Staphylococcus aureus, Bacillus anthracis, Vibrio parahaemolyticus, and Escherichia coli), and antioxidant potentials (2,2-diphenyl-1-picrylhydrazyl [DPPH] analysis).

### Materials and methods

#### Materials

The dried stem portion of E. senticosus (after removing thorns) was obtained from the Ginseng bank, Kyung Hee University, South Korea. Silver nitrate (AgNO\(_3\)) and Gold (III) chloride trihydrate (HAuCl\(_4\)·3H\(_2\)O) were purchased from Sigma-Aldrich Co. (St Louis, MO, USA). The rest of the chemicals used in this study were of analytical grade and used as received.

#### Metabolic analyses of E. senticosus

**Sample preparation**

A 50% ethanol solution was reported to be the best solvent for eleutheroside detection.\(^16\) Hence, 3 g of coarsely ground dried stem of E. senticosus was extracted with 30 mL of 50% ethanol under reflux for 1 hour. The extract was then filtered and evaporated in a rotary evaporator. After complete evaporation, 1 mL of high-performance liquid chromatography grade methanol was added, and the extract was used for LC-MS profiling. In a similar fashion, the extract was prepared for the total phenolic assay and total reducing sugar analysis.

#### LC-MS/MS for the detection of eleutherosides

LC-MS/MS analysis was performed as previously described with minor modifications.\(^16\) The experimental conditions are as follows: a negative mode of electrospray ionization (ESI) was employed with gas temperature of 350°C, nebulizer gas flow rate of 5 L min\(^{-1}\), at 60 psi, with capillary voltage of 2,500 V. Approximately 0.1% ammonium hydroxide was used as the solvent.

#### Total phenolic assay

The total phenolic content in the 50% ethanolic extract of E. senticosus was determined by the F-C method with minor modifications.\(^17\) Approximately 1 mL of the methanol extract was added to 1 mL of 10% sodium bicarbonate and incubated at room temperature for 5 minutes after vortexing. Following this, 1 mL of 2N F-C reagent was added to the mixture, it was then vortexed, and incubated in the dark for 30 minutes. The absorbance was then recorded at 765 nm. The total phenolic content was calculated by using gallic acid as the standard. The analysis was performed in triplicate to ensure accuracy of the results.

### Estimation of total reducing sugars

The DNS method was employed to determine the content of total reducing sugars in the E. senticosus extract. DNS reagent was prepared in line with the previously established
method. For the analysis, 1 mL of the DNS reagent was added to 1 mL of extract, which was then boiled at 90°C for 10 minutes. The absorbance was then measured at 540 nm after the reaction mixture was cooled to room temperature. The total reducing sugar content was estimated using glucose as the standard. Three replicates were carried out to prove the reproducibility of the experiment.

**Preparation of crude extract for nanoparticle synthesis**

The dried stem portion of *E. senticosus* was powdered using a commercial blender. Approximately 10 g of the coarse powder was boiled (100°C) in 150 mL of sterile water for 30 minutes. The collected extract was filtered and then centrifuged at 10,000 rpm for 10 minutes to remove the suspended materials. The collected supernatant was stored at −20°C and was used as a stock solution for the synthesis of silver and gold nanoparticles.

**Synthesis of silver and gold nanoparticles**

Approximately 1 mM silver nitrate (AgNO₃) and gold (III) chloride trihydrate (HAuCl₄·3H₂O) were used for *E. senticosus*-mediated nanoparticle synthesis. The syntheses of silver and gold nanoparticles were carried out using various concentrations of the plant extract (1:1, 1:2, and 1:3 dilutions of the extract). The concentration that gave the best results was further tested across different temperatures (−23°C, 40°C, and 80°C) and various time intervals. The reaction mixture was centrifuged at 17,000 rpm for 20 minutes for the extraction of Sg-AgNPs and Sg-AuNPs. The pelleted particles were further purified by recrystallizing the dispersed particles in sterile water three times to remove the water soluble biomolecules that were present. From this experiment, the best synthesis conditions were established, and these conditions were employed for the mass production of nanoparticles for further characterization and evaluation of their biological activities.

**Characterization of synthesized nanoparticles**

To confirm the reduction of the silver salt, the appropriate reaction mixture was scanned between 300 and 800 nm in a UV-Vis spectrophotometer (2100 Pro; Amersham Biosciences Corp., Piscataway, NJ, USA). The morphology and elemental distribution of the nanoparticles were evaluated using Ultrospec (FE-TEM), EDX, and elemental mapping with a JEM-2100F (JEOL, Tokyo, Japan) operated at 200 kV. The nanoparticle samples were loaded on a carbon-coated copper grid and oven dried at 60°C before microscopic analysis.

Dynamic light scattering analysis was carried out with a particle size analyzer (Photocal; Otsuka Electronics Co., Osaka, Japan) at 25°C to determine the hydrodynamic diameter and polydispersity index of the Sg-AgNPs and Sg-AuNPs. Pure water (refractive index of 1.3328; viscosity of 0.8878; dielectric constant of 78.3) was used as the reference dispersive medium. Nanoparticle samples that were washed with water three times and air dried were used for the X-ray diffraction and FTIR analyses. An X-ray diffractometer, D8 Advance (Bruker, Billerica, MA, USA), with a set of defined configurations (40 kV; 40 mA; CuKα radiation 1.54 Å; a scanning rate of 6°/min; step size 0.02; over the 2θ range of 20°–80°) was used to confirm the three dimensional configuration and crystallinity of the nanoparticles. FTIR was performed using a FTIR spectrophotometer (PerkinElmer Inc., Waltham, MA, USA) in the range of 450–4,000 cm⁻¹ at a resolution of 4 cm⁻¹. The stability of Sg-AgNPs and Sg-AuNPs was analyzed after incubating them at room temperature for a period of 1 month. The absorbance was then measured by UV-Vis spectrophotometer to check the stability.

**Evaluating the biological activities of Sg-AgNPs and Sg-AuNPs**

**Anticancer activity**

The cytotoxicity of Sg-AgNPs and Sg-AuNPs against the HaCaT and MCF7 cell lines was analyzed by MTT assay. These cells were seeded onto 96-well plates at a density of 1×10⁴ per well (Corning Costar, Lowell, NY, USA) and were then treated with different concentrations of Sg-AgNPs and Sg-AuNPs (1, 10, and 100 µg·mL⁻¹) for 72 hours. Approximately 10 µL of MTT solution (5 µg·mL⁻¹) was then added to each well and incubated for another 4 hours. Following this, all of the solutions were removed by aspiration, and the resulting formazan product was dissolved in 100 µL of dimethyl sulfoxide (DMSO) and incubated in the dark for 30 minutes. The absorbance of each well was recorded at 570 nm on a microplate reader (Bio-Tek Instruments, Inc., Vinooski, VT, USA). Untreated cells were used as the control.

**Antibacterial activity**

The antibacterial activity of Sg-AgNPs and Sg-AuNPs were evaluated against *S. aureus* (ATCC 6538), *B. anthracis* (NCTC 10340), *V. parahaemolyticus* (ATCC 33844), and *E. coli* (BL21) by the disc diffusion assay. An overnight log culture (100 µL of 0.2 optical density [OD] at 600 nm) of these microbes was evenly spread on Luria-Bertani agar plates. Following this, autoclaved paper discs were placed in the plates. Three different concentrations of Sg-AgNPs
and Sg-AuNPs namely 10, 20, and 30 µg·mL⁻¹ were added to these paper discs. Subsequently, the plates were incubated at 37°C, and after 24 hours they were analyzed for antimicrobial effects. This experiment was performed in triplicate to confirm the accuracy and precision.

**Antioxidant activity (DPPH analysis)**

The antioxidant activity of Sg-AgNPs and Sg-AuNPs was determined through DPPH analysis with minor modifications. Four different concentrations of nanoparticles (50, 100, 250, and 500 µg·mL⁻¹) were mixed with 1 mL of 0.1 mM DPPH and then incubated in the dark for 30 minutes. Subsequently, the absorbance was measured at 517 nm with ascorbic acid as the positive control. The free radical scavenging activity was determined by the formula, % inhibition = ((control OD - sample OD)/control OD)×100. Three replications were performed to enhance the reliability of the analysis.

**Results and discussion**

A schematic overview of the Siberian ginseng-mediated synthesis of silver and gold nanoparticles is depicted in Figure 1.

**Metabolic analyses of E. senticosus**

LC-MS profiling, total phenolic analysis, and total reducing sugar assay were performed in order to metabolically characterize the sample. In the present study, LC-MS analysis of the ethanolic extract revealed the presence of eleutheroside A corresponding to m/z 396, which could be correlated to the loss of O-glucose, while eleutheroside E was observed at m/z 401, owing to the loss of O-glucose and glucose (Figure 2), as reported in an earlier study.¹⁶

The F-C method was utilized to profile the total phenolics. This method relies on the movement of electrons from phenolic compounds to the phosphomolybdic/phosphotungstic acid complexes under alkaline conditions, resulting in a color change, which is determined spectrometrically at 765 nm.²⁰ The total phenolic content was estimated to be around 241 µg·mL⁻¹ of the extract. DNS analysis was used to detect the total reducing sugars present in the sample. DNS (yellow color) is reduced to 3-amino-5-nitro salicylic acid (orange-red color) by the reducing sugars in the presence of a strong base, which can be detected by the change in absorbance.²¹,²² The total amount of reducing sugars was found to be 4.5 mg·mL⁻¹ of the extract.

**Optimization of conditions for synthesis of Sg-AgNPs and Sg-AuNPs**

The standardization of reaction conditions was performed to determine optimal concentration of plant extract, temperature, and time. For the synthesis of silver nanoparticles, the addition of 1 mM AgNO₃ to 1:1 diluted plant extract incubated at 80°C for 1.5 hours showed the best results. Whereas, in the case of synthesis of gold nanoparticle, addition of 1 mM HAuCl₄·3H₂O to 1:1 diluted plant extract incubated at
room temperature for 9 minutes was preferred. Based on the UV-Vis data, it was inferred that temperature did not play a major role in the synthesis of gold nanoparticles (Figure 3). These optimized conditions were used for mass production of nanoparticles for further analyses.

**Synthesis and physiochemical characterization of silver and gold nanoparticles**

The crude extract of *E. senticosus* exhibited the capacity to reduce AgNO$_3$ and HAuCl$_4$·3H$_2$O to result in the formation of silver and gold nanoparticles, respectively, which was indicated by the color change in the reaction mixture. Approximately 1 mM of AgNO$_3$ was completely reduced to Sg-AgNPs upon incubation at 80°C for 1.5 hours, which was indicated by the change in color of the reaction mixture from light yellow to dark brown. In addition, time-dependent UV spectroscopy over the range of 300–800 nm resulted in a strong peak at approximately 440 nm, which could be attributed to the surface plasmon resonance band of the silver nanoparticles (Figure 3A). Upon the addition of 1 mM HAuCl$_4$·3H$_2$O in the reaction mixture at room temperature, its color changed from light yellow to deep purple. Time-dependent UV spectroscopy over the range of 300–800 nm revealed the peak at 575 nm, corresponding to the surface plasmon resonance band of gold nanoparticles (Figure 3D). For the spectrometric analysis, the absorption spectrum of the extract was used as the control.

TEM analysis exhibits 1,000-fold more resolution than SEM and hence is most commonly used for analyzing the shape of the nanoparticles. FE-TEM analysis indicated that both the silver and gold nanoparticles were predominantly spherical (Figure 4). Their purity and elemental composition were analyzed through EDX and elemental mapping (Figure 4). In the EDX spectrum, the silver and gold nanoparticles exhibited an optical absorption band peak at ~3 and 2.3 keV, respectively. These results are in line with the previous reports. The dynamic light scattering particle size analysis revealed that the Z-average hydrodynamic diameters of Sg-AgNPs and Sg-AuNPs were approximately 126 and 189 nm, respectively (Figure 5). The polydispersity index of Sg-AgNPs was found to be 0.25, while that of Sg-AuNPs was 0.10. The X-ray diffraction pattern of both the silver and gold nanoparticles displayed five diffraction peaks at 2θ = 38.62°, 44.72°, 65.02°, 77.84°, and 81.90°, which could be attributed to the (111), (200), (220), (311), and (222) planes of face-centered cubic-shaped crystalline silver and gold nanoparticles (Figure 6A and B). Similar results were documented in other studies. In addition, selected area electron diffraction pattern also reconfirmed the crystalline nature (Figure 4). The average crystallite size was determined from X-ray diffraction analysis data using the Scherrer equation. It was found to be 14.63 nm and 8.01 nm for Sg-AgNPs and Sg-AuNPs, respectively. The contradiction in the average crystallite diameter obtained from the Scherrer equation and Z-average hydrodynamic diameter from the dynamic light scattering analysis particle size analysis could be attributed to the fact that the hydrodynamic diameter is inclusive of plant biomolecule coatings.
The fundamental parameters for the synthesis of nanoparticles, namely, time, concentration of the plant extract, and temperature were optimized.

Notes: For the synthesis of Sg-AgNPs, a time period of 1.5 hours (A), 1:1 diluted plant extract (B), and a temperature of 80°C (C) gave the best results. Similar results were obtained for Sg-AuNPs in regard to the concentration of the plant extract (D); however, the optimal synthesis time was only 9 minutes (E). The temperature was not found to play a significant role in the synthesis of Sg-AuNPs (F). The square boxes beside each figure indicate the color of the appropriate nanoparticles upon the described conditions.

Abbreviations: OD, optical density; Sg-AgNPs, Siberian ginseng silver nanoparticles; Sg-AuNPs, Siberian ginseng gold nanoparticles; h, hours; min, minutes.
Figure 4 Physicochemical characterization of Sg-AgNPs (A) and Sg-AuNPs (B).

Notes: Field emission transmission electron micrographs showed that both Sg-AgNPs and Sg-AuNPs are predominantly spherical in shape (Ai, Aiii, Bi, and Biii) and the selected area electron diffraction pattern revealed the crystalline nature of the biosynthesized nanoparticles (Aii and Bii). Elemental mapping (Aiv and Biv) and energy dispersive X-ray spectroscopy (Av and Bv) confirmed the purity of the nanoparticles.

Abbreviations: Sg-AgNPs, Siberian ginseng silver nanoparticles; Sg-AuNPs, Siberian ginseng gold nanoparticles.
upon the nanoparticle, whereas the crystallite diameter is solely its core diameter.

FTIR analysis revealed intense bands at 3,420.77, 2,915.90, 2,848.28, 1,627.08, 1,505.59, and 1,017.87 cm\(^{-1}\) for silver nanoparticles, and at 1,644.84, 1,324.15, and 780.38 cm\(^{-1}\) for gold nanoparticles (Figure 6C and D). Bands in the range of 3,500–3,000 cm\(^{-1}\) represent –N–H and OH–O stretching. The peaks at 2,915.90 and 2,848.16 cm\(^{-1}\) could be attributed to –CH\(_2\) asymmetric stretching. The band at 1,633.85 cm\(^{-1}\) could be equated to an amide 1 bond of the polypeptides.\(^{25}\) Peaks ranging from 1,650 to 1,450 cm\(^{-1}\) indicate the presence of an aromatic ring and elongation of the aromatic C=\(\text{C}\) bonds. The bands between 1,100 and 1,010 cm\(^{-1}\) in the spectrum were assigned to C–O and C–H chemical bonds. Peaks ranging from 910–740 cm\(^{-1}\) could be due to the deformation vibration of C–H bonds in the phenolic rings.\(^{26}\) The deformation vibration of the C–C bonds in the phenolic groups creates peaks between 1,500 and 1,400 cm\(^{-1}\).\(^{27}\) In line with this, the peaks
present in the FTIR graph of Sg-AgNPs indicate that proteins and other aromatic organic molecules of *E. senticosus* could most likely play a key role in the synthesis and stabilization of the silver nanoparticles. In the case of Sg-AuNPs, the obtained data suggest that phenolic compounds of *E. senticosus* could mainly be responsible for the reduction of HAuCl$_4$·3H$_2$O to gold nanoparticles. Moreover, these phenolic compounds are predicted to form a coating around the nanoparticles, thereby contributing to their stability.

The stability of the both Sg-AgNPs and Sg-AuNPs were analyzed by incubating them at room temperature for a period of 1 month. There was no significant deviation in the UV-Vis spectrum in the range of 300–800 nm after the month-long incubation, confirming the stability of the synthesized nanoparticles.

**Effect of the silver and gold nanoparticles on the breast cancer cell line MCF7**

Breast cancer is the most predominant type of cancer in women. In 2015, approximately 231,840 of women in the US were affected with breast cancer, which accounted for 29% of the total number of cancer cases in women. Chemotherapy and radiotherapy are a few of the commonly employed treatments for breast cancer, and unfortunately, these treatments leave serious side effects. Therefore, studies using nanoparticles in the treatment of cancer have been performed by many research groups to potentially enhance cancer treatment with minimal or no side effects.

In the present study, the synthesized silver and gold nanoparticles were analyzed for cytotoxicity by the MTT assay for 72 hours on HaCaT (normal keratinocyte cell line) and MCF7 (breast cancer cell line). At 10 μg·mL$^{-1}$ concentration, the Sg-AgNPs conferred 40% cytotoxicity in the MCF7 cell line, whereas there was only 17% cytotoxicity in the HaCaT cell line (Figure 7A and B). A positive correlation between the dosage of Sg-AgNPs and cytotoxicity rate was documented. Contrastingly, the gold nanoparticles did not exhibit any cytotoxicity in both HaCaT and MCF7 cell lines (Figure 7C and D). With a concentration as high as 100 μg·mL$^{-1}$ of Sg-AuNPs, viability was ~95% in both of the cell lines.

![Figure 7](https://example.com/figure7.png)

**Figure 7** The MTT assay was used to examine the effect of various concentrations of Sg-AgNPs on the viability of the human keratinocyte cell line, HaCaT (A), the breast cancer cell line, MCF7 (B) and the effect of Sg-AuNPs on the viability of the HaCaT (C) and MCF7 cell lines (D).

**Notes:** The cells were incubated with the nanoparticles for 72 hours, and the experiment was repeated three times. Error bars represent the standard deviation (n=3). **P<0.001 versus control (untreated group). The statistical significance of differences between values was evaluated by one-way ANOVA. At 10 μg·mL$^{-1}$, the Sg-AgNPs led to 40% cytotoxicity in the MCF7 cell line, but only 17% cytotoxicity in the HaCaT cell line. Sg-AuNPs did not show any cytotoxic effects.

**Abbreviations:** ANOVA, analysis of variance; MTT, 3-(4,5-dimethyl-2-thiazolyl)-2,5-diphenyl-2H tetrazolium bromide; Sg-AgNPs, Siberian ginseng silver nanoparticles; Sg-AuNPs, Siberian ginseng gold nanoparticles.
This finding opens up the possibility of using Sg-AuNPs in drug delivery and molecular imaging techniques.

**Evaluation of antibacterial activity**

The antibacterial efficacy of the Sg-AgNPs and Sg-AuNPs were evaluated in Luria-Bertani agar against the gram-positive *S. aureus* (ATCC 6538), *B. anthracis* (NCTC 10340), and gram-negative *V. parahaemolyticus* (ATCC 33844), and *E. coli* (BL21) using the disc diffusion method (Figure S1). Neomycin was used as the positive control for *S. aureus* and *E. coli*, whereas oleandomycin and vancomycin were employed as positive controls for *B. anthracis* and *V. parahaemolyticus*, respectively. In the case of Sg-AgNPs, the minimum inhibitory concentration (MIC) was 9 µg·mL⁻¹ against all of the bacteria. The zone of inhibition increased with an increase in concentration. On the other hand, Sg-AuNPs did not show any zone of inhibition irrespective of the concentration used. These results are tabulated in Table 1. This clearly indicates that the silver nanoparticles confer toxicity against both gram-positive and gram-negative bacteria, as reported in the past. The mechanism related to the antibacterial activity of Sg-AgNPs remains to be elucidated. Silver nanoparticles have the capacity to damage the cell wall of both gram-positive and gram-negative bacteria, thereby killing them. In line with this, Sg-AgNPs might have degraded the cell wall, leading to the death of the bacteria. However, further studies are required to confirm this assumption. Sg-AgNPs have the potential to be utilized in the disinfection of surgical instruments, thereby preventing cross-contamination and enhancing safety levels in hospitals.

**Assessment of antioxidant activity**

The free radical scavenging efficacy of Sg-AgNPs and Sg-AuNPs was determined through the DPPH assay. Upon accepting hydrogen (H) from the antioxidant, DPPH reduces to DPPH₂, thus resulting in the change of color from purple to yellow which is associated with a characteristic decrease in absorbance at 515 nm. Approximately 50% DPPH inhibition was recorded at 100 and 250 µg·mL⁻¹ concentrations of Sg-AgNPs and Sg-AuNPs, respectively. In addition, Sg-AgNPs and Sg-AuNPs demonstrated significantly higher antioxidant activity than their corresponding salts (Figure 8).

During unfavorable conditions, reactive oxygen species levels are elevated in human cells, which lead to cancer, accelerated aging, and other major disorders. In the present study, MTT results indicated that Sg-AuNPs did not display any cytotoxicity to both the HaCaT and MCF7 cell lines. Therefore, Sg-AuNPs could be effectively employed to scavenge free radicals synthesized in the cell in response to multiple stresses. The antioxidant potential of gold nanoparticles has been reported earlier. Moreover, Sg-AuNPs could also be combined with cosmetics to enhance skin texture and prevent aging symptoms.

**Table 1** Determination of the antibacterial activity of Sg-AgNPs and Sg-AuNPs by the disc diffusion assay in terms of the zones of inhibition

| Microbe                  | Zone of inhibition (mm) | Sg-AgNPs | Sg-AuNPs |
|--------------------------|-------------------------|----------|----------|
|                          | Positive control | 10 µg | 20 µg | 30 µg | Positive control | 10 µg | 20 µg | 30 µg |
| *Staphylococcus aureus*  | 16.5±0.2               | 11.0±0.3 | 12.3±0.1 | 13.8±0.2 | 17.9±0.3 | 0.0 | 0.0 | 0.0 |
| *Bacillus anthracis*     | 19.0±0.1               | 10.7±0.2 | 12.0±0.3 | 13.2±0.2 | 18.0±0.3 | 0.0 | 0.0 | 0.0 |
| *Vibrio parahaemolyticus*| 10.0±0.4               | 11.5±0.3 | 12.9±0.2 | 13.7±0.1 | 10.5±0.2 | 0.0 | 0.0 | 0.0 |
| *Escherichia coli*       | 18.3±0.1               | 12.0±0.4 | 12.8±0.5 | 13.3±0.3 | 17.7±0.5 | 0.0 | 0.0 | 0.0 |

*Note:* It was interpreted that the Sg-AgNPs were efficient against both gram-positive and gram-negative bacteria.

*Abbreviations:* Sg-AgNPs, Siberian ginseng silver nanoparticles; Sg-AuNPs, Siberian ginseng gold nanoparticles.
Conclusion
This report describes a method for the biological synthesis of silver and gold nanoparticles from the herbal adaptogen *E. senticosus*, which is simple, efficient, and ecofriendly. Physicochemical characterization revealed the structural and chemical properties of the nanoparticles. MTT analysis indicated that at 10 µg·mL⁻¹, Sg-AgNPs could be effectively employed in breast cancer treatments. As Sg-AuNPs did not possess cytotoxicity across the selected concentration range, they could potentially be used as carriers in drug delivery as well as in molecular imaging techniques. Sg-AgNPs exhibited inhibitory effects against *S. aureus* (ATCC 6538), *B. anthracis* (NCTC 10340), *V. parahaemolyticus* (ATCC 33844), and *E. coli* (BL21), which sheds light on their application as a sterilizing agent for surgical instruments. In addition, both silver and gold nanoparticles were found to be efficient antioxidants. As the MTT analysis indicated that Sg-AuNPs were not cytotoxic, they can be effectively used in combination with cosmetics to prevent the symptoms of aging. We strongly believe that this study would open up doors for large-scale utilization of the multifunctional Sg-AgNPs and Sg-AuNPs, which would indirectly aid in reaping the benefits of endemic *E. senticosus*.

Supplementary material

**Figure S1** The disc diffusion method demonstrates the effects of various concentrations of biosynthesized nanoparticles.

Notes: The effects of various concentrations (10, 20, and 30 µg mL⁻¹) of biosynthesized nanoparticles on the gram-positive *Staphylococcus aureus* (Sg-AgNPs [A] and Sg-AuNPs [B]) and *Bacillus anthracis* (Sg-AgNPs [C] and Sg-AuNPs [D]). Similarly, their antibacterial effect was tested on gram-negative *Vibrio parahaemolyticus* (Sg-AgNPs [E] and Sg-AuNPs [F]) and *Escherichia coli* (Sg-AgNPs [G] and Sg-AuNPs [H]). In the case of Sg-AgNPs, the zone of inhibition increased with an increase in the concentration of nanoparticles, whereas Sg-AuNPs did not show any antibacterial activity in the selected concentration range.

Abbreviations: Sg-AgNPs, Siberian ginseng silver nanoparticles; Sg-AuNPs, Siberian ginseng gold nanoparticles.
