Abstract

Background: Tension-type headache is a common neurological problem among general population of Bangladesh. Objective: This study was undertaken to ascertain the frequency of subclinical and overt hypothyroidism in patients with infrequent TTH. Methodology: This study was conducted in a tertiary care hospital Dhaka medical college in Bangladesh. The study subjects consisted of 200 patients primary headache disorders. Thyroid function test were performed. All four sub-types of tension type headache were considered to include in the study, namely: Infrequent episodic (or infrequent), frequent episodic (or frequent), chronic sub-type and probable sub-type. Result: Forty percent (40%) patients in this study had infrequent TTH, 30% had frequent episodic TTH, 21% had chronic sub-type of TTH and 9% patients had probable sub-type of TTH. overt hypothyroidism. Among 46 patients with frequent episodic TTH 10 patients had subclinical hypothyroidism and 4 patients had overt hypothyroidism. Out of 18 patients with probable TTH 3 patients had subclinical hypothyroidism but no patient was overt hypothyroid. Out of 42 chronic TTH patients 12 had subclinical and another 12 had overt hypothyroidism. Statistically significant difference was seen among different sub-types of headache in relation to thyroid status. Conclusion: Hypothyroidism is found to be a co morbidity or precipitating factors to be development of infrequent type of tension-type headache. Keywords: : Hypothyroidism; Tension-Type Headache; TTH; neurological disorder

Introduction

Tension-type headache is a neurological disorder characterized by recurrent episodes of headache lasting 30 minutes to 7 days1. The pain is typically pressing or tightening in quality, of mild to moderate intensity, and bilateral in location, and does not worsen with routine physical activity. Nausea and vomiting is usually absent, but photophobia or phonophobia may be present2. These headaches were previously known by many terms such as psychogenic headache, stress headache, psychomyogenic headache, muscle contraction headache etc. However, the term “tension type headache” (TTH)
has been chosen by the International Classification
Headache Diagnosis I (ICHD I) and have been retained
by ICHD II1.

Tension-type headache (TTH) is the most prevalent form
of headache in all age groups across the globe 2. TTH
leads to considerable disability with up to 60.0% of
individuals reporting decreased work effectiveness,
increased absenteeism and reduced social engagement3.
The underlying cause of tension-type headache is
uncertain. Activation of Hyper excitable peripheral
afferenent neurons from head and neck muscles might be
the likely explanation for tension-type headache4. Muscle
tenderness and psychological tension may aggravate
tension-type headache but are not clearly its cause.
Abnormalities in central pain processing and generalized
increased pain sensitivity are present in some patients
with tension-type headache5.

There are several consistent studies have shown that
patients with TTH had significantly higher proportion of
subclinical hypothyroidism and overt hypothyroidism as
compared to the control subjects6. It has been observed
that improvement in headache occurs in 30% of
hypothyroid patients after initiation of thyroid hormone
replacement7. There have been few recent advances in
treatment options for TTH. Non pharmacologic approach
like avoidance of associated factors and reassurance has
been proved useful in several studies8. As far the
knowledge goes this will be the first study in Bangladesh
to find out the relationship between hypothyroidism and
tension-type headache. The overall response to treatment
of TTH is often not satisfactory. For a majority of
individuals with TTH, the mainstay in pharmacotherapy
is simple analgesics and non-steroidal anti-inflammatory
drugs9. This study was undertaken to ascertain the
frequency of subclinical and over hypothyroidism in
patients with infrequent TTH.

Methodology

It was a cross sectional observational study. Data were
collected from the department of Neurology (Headache
Clinic), Dhaka Medical College Hospital, Dhaka,
Bangladesh. Patient with tension-type headache
attending in headache clinic in DMCH with the age
group 18 to 55 years of age of both male and female
with the diagnosis of tension type headache on the basis
of ICHD-2 criteria were selected as study population.
Patients with any form of thyroid disease prior to the
enrolment in the study as revealed by clinical
examination or past medical records or patients with
abnormal neurological examination, pregnancy, any
chronic illness known to affect thyroid hormone levels,
chronic kidney disease or other systemic illness or
chronic drug intake known to affect thyroid status of the
patient like lithium carbonate, amiodarone and
anti-thyroid drugs were excluded from this study.

Non-probability purposive consecutive sampling
method was used to select sample population. Data was
collected from the respondents through interview. At
first study subjects were screened according to
inclusion and exclusion criteria who complaint
headache. Then physical examination was done
accordingly. Diagnosis of the TTH was made on the
basis of ICHD-2 and verified by a consultant
neurologist. Following confirmation demographic
profile was collected by face-to-face interview by using
a semi-structured questionnaire. In all cases informed
written consent was taken after explaining the aims,
objectives of the study in each patient. Researcher filled
up whole of the questionnaire and patients were
requested to perform thyroid function test from Institute
of Nuclear Medicine and Allied Science (INMAS). All
the study subjects were tested for serum free T4 and
TSH by radio immune assay (RIA) and immune radio
metric assay (IRMA) using radioisotope 1-125 as tracer.

Personal contact numbers were collected during
interview and patients were followed up in prefixed
scheduled date. During follow up visit, hormonal level
were included in their personal data sheet and
researcher himself ascertained subtypes of
hypothyroidism. Moreover, following primary
screening endocrine abnormality were also confirmed
by an endocrinologist. Subjects with incomplete data
were excluded before final analysis. Also in case of
hyperthyroidism the patients were excluded from the
study and inclusion of another patient was done until it
matched 200 samples. Based on TTH and serum T4 and
TSH level, study population were divided into two
groups designated as group I representing the patients
with euthyroid and group II consisted with the patients
with hypothyroidism either overt or subclinical. After
collecting the data, it was checked and rechecked for
omission, inconsistencies and improbabilities. After
cleaning the data it was edited, coded and entered into
the computer. Statistical analysis of the study was done
by computer software device as the Statistical Package
for Social Science (SPSS) version 22.0. Confidence
interval was considered at 95% level. The qualitative
variables were expressed as frequency and percentage
and the quantitative variables were expressed as mean
with standard deviation. During analysis chi-square test
was done to estimate the relationship or association
between TTH and hypothyroidism. P value less than
0.05 was considered statistically significant.

Results
This study was conducted on 200 patients who met the ICHD-2 diagnostic criteria of Tension Type Headache. Mean age of the patients studied was 35.4 years (±9.9). Among the respondents, minimum age was 18 years and maximum age was 55 years. Majority of the patients (31.0%) were in between 36 to 45 years (Table 1).

Table 1: Age Group of the Respondents (n=200)

| Age Group     | Frequency | Percent |
|---------------|-----------|---------|
| 18 to 25 Years| 48        | 24.0    |
| 26 to 35 Years| 50        | 25.0    |
| 36 to 45 Years| 62        | 31.0    |
| 46 to 55 Years| 40        | 20.0    |
| Total         | 200       | 100.0   |

Among 200 patients majority (80 patients, 40%) had infrequent episodic tension type headache (TTH). Next to infrequent episodic TTH was frequent episodic TTH with number of 60(30%). 42(21%) patients had chronic sub-type of TTH and remaining 18(9.0%) patients had probable sub-type of TTH (Figure I).

This study focused on patients of TTH who had hypothyroidism or normal thyroid status. As a result, patients who were found hyperthyroid were excluded from the study. Out of 200 patients with TTH total 61 patients (30.5%) had hypothyroidism and rest of them (139 patients, 69.5%) had normal thyroid status. Among the 61 hypothyroid patients subclinical hypothyroidism was found in 41 patients and 20 patients had overt hypothyroidism (Figure II).

Table 2: Thyroid status in relation of different sub-types of TTH (n=200)

| TTH Sub-types | Subclinical Hypothyroidism | Overt Hypothyroidism | Normal Status | Total | P Value |
|---------------|---------------------------|----------------------|---------------|-------|---------|
| Infrequent    | 16                        | 4                    | 60            | 80    | 0.0001  |
| Frequent      | 10                        | 4                    | 46            | 60    |         |
| Chronic       | 12                        | 12                   | 18            | 42    |         |
| Probable      | 3                         | 0                    | 15            | 18    |         |
| Total         | 41                        | 20                   | 139           | 200   |         |

*p value was measured by Pearson’s Chi-square Test
as having tension type headache (TTH). However, the underlying cause of TTH is uncertain in most of the cases. There are several studies that tried to find any link between hypothyroidism and TTH\(^5\)\(^6\). Two of them were undertaken on small sample population and found no link\(^11\)\(^\text{12}\). Rest of them had found a variable number of hypothyroid cases among TTH patients\(^8\). This study included 200 patients of different subtypes of TTH and tested for evidence of hypothyroidism.

All four sub-types of tension type headache were considered to include in the study, namely: Infrequent episodic or infrequent, frequent episodic or frequent, chronic sub-type and probable sub-type. Forty percent (40%) patients in this study had infrequent TTH, 30% had frequent episodic TTH, 21% had chronic sub-type of TTH and 9% patients had probable sub-type of TTH. In a study done by Khan et al\(^8\) in a tertiary care hospital of Kashmir, India they found among patients with TTH, 78 (47.6%), 52(31.7%) and 34(20.7%) had infrequent episodic TTH, frequent episodic TTH and chronic TTH respectively\(^4\). Their study used the ICHD-2 criteria for TTH but did not include any patients with probable TTH. In this aspect this present study was a unique one as it had included probable sub-type of TTH along with other subtypes. However, when proportions of other sub-types of headache are compared with the study conducted by Khan et al\(^8\) nearly equal results can be observed.

Prevalence of hypothyroidism in general population varies from country to country. Overall prevalence of subclinical hypothyroidism in general population is 4.0 to 10.0% cases\(^13\). In India prevalence of hypothyroidism is 10.9% cases\(^14\). In one study done in a community of Khulna district of Bangladesh prevalence of subclinical and overt hypothyroidism was found to be 6.59% and 4.97% respectively\(^15\). On the other hand, proportion of both subclinical (22%) and overt hypothyroidism (7.2%) was found high in TTH patients in the study done by Khan and colleagues\(^8\). In concordance with the later study, incidence of subclinical and overt hypothyroidism was found 20.5% (41) and 10% (20) respectively in this study. Jonathan R. Amy and Andrew J. Larner in their research did not find any patients of hypothyroidism in the sample population of headache\(^6\). This was either because of small sample size (only 20 in the earlier study) or because small proportion of sample was tested for thyroid status only 13 among 119 patients in the later study. From above studies it can be inferred that incidence of hypothyroidism is more in TTH than normal people.

Among 80 infrequent TTH patients 20 had hypothyroidism and among 42 chronic TTH patients 24 had hypothyroidism. The difference is statistically highly significant (p=0.0001). The difference in between frequent TTH and chronic TTH in relation to thyroid status (14 and 24 hypothyroid patients respectively) is also statistically significant (p=0.001). These findings again go along with the findings of Khan et al\(^8\) who compared difference between chronic and infrequent sub-type and in between chronic and frequent sub-type. This implies that chronic TTH patients are statistically more likely to be found hypothyroid than both frequent episodic and infrequent episodic patients.

There were a number of limitations of the study which includes small sample size. Considering the limitation of the time, logistic supports, availability of patients and lack of sufficient fund, sample size was considered 200. Further case-control study is needed to confirm the consistency of the findings.

### Conclusion

Headache particularly tension-type headache and hypothyroidism both affect the quality of life significantly. The study reveals positive correlation between two of them. However, without case-control study significant association between infrequent TTH and hypothyroidism cannot be established. However, from this study it is recommended that thyroid hormone level should be tested in each case of infrequent tension-type headache and hypothyroidism should be considered as a risk factor for primary headache disorder. More study is necessary for a more conclusive statement.
