Evidence for the baryonic decay $B^0 \rightarrow D^0 \Lambda\Lambda$
Evidence is presented for the baryonic \( B \) meson decay \( B^0 \to D^0 \Lambda \bar{\Lambda} \) based on a data sample of \( 471 \times 10^6 \) \( B \bar{B} \) pairs collected with the \textit{BABAR} detector at the PEP-II asymmetric e\(^{+}\)e\(^{-}\) collider located at the SLAC National Accelerator Laboratory. The branching fraction is determined to be \( \mathcal{B}(B^0 \to D^0 \Lambda \bar{\Lambda}) = (9.8^{+2.9}_{-2.4} \pm 1.9) \times 10^{-6} \), corresponding to a significance of 3.4 standard deviations including additive systematic uncertainties. A search for the related baryonic \( B \) meson decay \( B^0 \to D^0 \Sigma^0 \Lambda \) with \( \Sigma^0 \to \Lambda \gamma \) is performed and an upper limit \( \mathcal{B}(B^0 \to D^0 \Sigma^0 \Lambda + B^0 \to D^0 \Lambda \Sigma^0) < 3.1 \times 10^{-5} \) is determined at 90\% confidence level.

DOI: 10.1103/PhysRevD.89.112002 PACS numbers: 13.25.Hw, 13.60.Rj, 14.20.Lq

1. INTRODUCTION

Little is known about the mechanism of baryon production in weak decays or in the hadronization process. Baryons are produced in (6.8 ± 0.6)% of all \( B \) meson decays [1]. Due to this large rate, \( B \) meson decays can provide important information about baryon production. Due to the low energy scale, perturbative quantum chromodynamics (QCD) cannot be applied to this process. Furthermore, lattice QCD calculations are not available. The description of baryonic \( B \) decays thus relies on phenomenological models.

Pole models [2] are a common tool used in theoretical studies of hadronic decays. Meson pole models predict an enhancement at low baryon-antibaryon masses. In many three-body decays into a baryon, an antibaryon and a meson, the baryon-antibaryon pair, can be described by a meson pole, i.e., the decay of a virtual meson with a mass below threshold. This leads to a steeply falling amplitude at the threshold of the baryon-antibaryon mass and explains the enhancement observed in decays such as \( B^- \to \Lambda p \pi^- [3,4], B^- \to p \bar{p} K^- [5–7], \) and \( B^0 \to D^0 p \bar{p} [8,9] \).
In addition to the meson pole models described above, there are baryon pole models in which the initial state decays through the strong interaction into a pair of baryons. Then, one of these baryons decays via the weak interaction into a baryon and a meson. For such baryon pole models, no enhancement at threshold in the dibaryon invariant mass is expected.

The decay of a $B$ meson into a $D^0$ meson and a pair of baryons has been the subject of several theoretical investigations [10,11]. Reference [11] predicts the branching fractions for these four modes and that the spin-$\bar{B}$ expected for $\Sigma$-meson production is suppressed by about a factor of three compared to only one for a $\Lambda$-meson [12]. Furthermore, there are no previous results corresponding to $\Lambda$-baryons. The decay of a $\Lambda$ baryon through the decay mode $\Lambda \rightarrow p\pi^-$ and $D^0$ mesons through the modes $D^0 \rightarrow K^-\pi^+$, $D^0 \rightarrow K^-\pi^+\pi^-$, and $D^0 \rightarrow K^-\pi^+\pi^0$ [19]. Charged kaon and proton candidates are required to satisfy particle identification criteria. Charged pions are selected as charged tracks that are not identified as a kaon or proton. Candidate $n^0$ mesons are reconstructed from two separated energy deposits in the electromagnetic calorimeter not associated with charged tracks. To discriminate against neutral hadrons, the shower shape of each deposit is required to be consistent with that of a photon [20]. Furthermore, we require $E(\gamma_1) > 0.125$ GeV and $E(\gamma_2) > 0.04$ GeV, where $E(\gamma_1)$ and $E(\gamma_2)$ are the energies of the photon candidates, with $E(\gamma_1) > E(\gamma_2)$. The photon-photon invariant mass is required to lie in the range $m(\gamma\gamma) \in [0.116, 0.145]$ GeV/c$^2$.

The $\Lambda$ daughters are fit to a common vertex and the reconstructed mass is required to lie within three standard deviations.

**III. RECONSTRUCTION OF A BARYON, $D^0$ MESON, AND $\bar{B}^0$ MESON CANDIDATES**

We reconstruct $\Lambda$ baryons through the decay mode $\Lambda \rightarrow p\pi^-$. The $D^0$ mesons are reconstructed using the $B^0 \rightarrow D^0\bar{D}^0$ final state and the $D^0\bar{D}^0$ pairs, collected with the $\Lambda$-meson pole models described above, $B^0 \rightarrow D^0\Lambda\bar{\Lambda}$, $B^0 \rightarrow D^0\Sigma^0\bar{\Lambda}$, and $B^0 \rightarrow D^0\Sigma^0\bar{\Lambda}$ final states.

**II. THE BABAR EXPERIMENT**

This analysis is based on a data sample of 429 fb$^{-1}$ [14], corresponding to $471 \times 10^6$ $BB$ pairs, collected with the BABAR detector at the PEP-II asymmetric-energy $e^+e^-$ collider at the SLAC National Accelerator Laboratory at center-of-mass energies near and equal to the $Y(4S)$ mass. The reconstruction efficiency is determined through use of Monte Carlo (MC) simulation, based on the EvtGen [15] program for the event generation and the GEANT4 [16] package for modeling of the detector response. The MC events are generated uniformly in the $B^0 \rightarrow D^0\Lambda\bar{\Lambda}$ and $B^0 \rightarrow D^0\Sigma^0\bar{\Lambda}$ phase space.

The BABAR detector is described in detail elsewhere [17,18]. Charged particle trajectories are measured with a five-layer double-sided silicon vertex tracker and a 40-layer drift chamber immersed in a 1.5 T axial magnetic field. Charged particle identification is provided by ionization energy measurements in the tracking chambers and by Cherenkov-radiation photons recorded with an internally reflecting ring-imaging detector. Electrons and photons are reconstructed with an electromagnetic calorimeter.
EVIDENCE FOR THE BARYONIC DECAY

deviations of the nominal value [1], where the standard deviation is the mass resolution. We select \( \Lambda \) candidates by requiring the flight significance \( L_f/\sigma_L \) to exceed 4, where \( L_f \) is the \( \Lambda \) flight length in the transverse plane and \( \sigma_L \) its uncertainty. The \( \Sigma^0 \) baryons are produced in the decay \( \Sigma^0 \rightarrow \Lambda \gamma \), and the photon is not reconstructed.

The \( D^0 \) candidates daughter candidates are fit to a common vertex, and the reconstructed mass is required to lie within three times the mass resolution from their nominal values [1]. The signal-to-background ratio for \( D^0 \rightarrow K^-\pi^+\pi^0 \) is improved by making use of the resonant substructure of this decay, which is well known. Using results from the E691 Collaboration [21], we calculate the probability \( w_{\text{Dalitz}} \) for a \( D^0 \) candidate to be located at a certain position in the Dalitz plane. We require \( w_{\text{Dalitz}} > 0.02 \). Figure 2 shows the Dalitz plot distributions, based on simulation, for candidates selected with and without the \( w_{\text{Dalitz}} \) requirement.

The \( D^0 \) and \( \Lambda \) candidates are constrained to their nominal masses in the reconstruction of the \( \bar{B}^0 \) candidates. We apply a fit to the entire decay chain and require the probability for the vertex fit to be larger than 0.001.

To reduce background from \( e^+e^- \rightarrow q\bar{q} \) events with \( q = u, d, s, c \), we apply a selection on a Fisher discriminant \( F \) that combines the values of \( |\cos \theta_{\text{Thrust}}| \), where \( \theta_{\text{Thrust}} \) is the angle between the thrust axis of the \( B \) candidate and the thrust axis formed from the remaining tracks and clusters in the event; \( |\cos \theta_z| \), where \( \theta_z \) is the angle between the \( B \) thrust axis and the beam axis; and \( |\cos \phi| \), where \( \phi \) is the angle between the \( B \) momentum and the beam axis; and the normalized second Fox-Wolfram moment [22]. All these quantities are defined in the center-of-mass frame. All selection criteria are summarized in Table I.

### IV. FIT STRATEGY

We determine the number of signal candidates with a two-dimensional unbinned extended maximum likelihood fit to the invariant mass \( m(D^0\Lambda \bar{\Lambda}) \) and the energy-substituted mass \( m_{ES} \). The latter is defined as

\[
m_{ES} = \sqrt{(s/2 + p_B \cdot p_B)^2/E_{ES}^2 - |p_B|^2},
\]

where \( \sqrt{s} \) is the center-of-mass energy, \( p_B \) the \( B \) candidate’s momentum, and \( (E_{ES}, p_0) \) the four-momentum vector of the \( e^+e^- \) system, each given in the laboratory frame. Both \( m(D^0\Lambda \bar{\Lambda}) \) and \( m_{ES} \) are centered at the \( B \) mass for well-reconstructed \( B \) decays.

Due to the small mass difference of 76.9 MeV/c\(^2\) [1] between the \( \Lambda \) and \( \Sigma^0 \) baryons, \( \bar{B}^0 \rightarrow D^0\Sigma^0 \bar{\Lambda} \) decays, where the \( \Sigma^0 \) decays radiatively as \( \Sigma^0 \rightarrow \Lambda \gamma \), are a source of background. Such events peak at the \( B \) mass in \( m_{ES} \) and are slightly shifted in \( m(D^0\Lambda \bar{\Lambda}) \) with respect to \( \bar{B}^0 \rightarrow D^0\Lambda \bar{\Lambda} \) (Fig. 3). We account for this decay by including an explicit term in the likelihood function (see below), whose yield is determined in the fit.

We divide the data sample into three subsamples corresponding to the \( D^0 \) decay modes. Given their different signal-to-background ratios, we determine the number of signal candidates in a simultaneous fit to the three independent subsamples. We study simulated samples of signal and background events and find no significant correlation between \( m_{ES} \) and \( m(D^0\Lambda \bar{\Lambda}) \). Therefore, we describe each \( B^0 \rightarrow D^0\Lambda \bar{\Lambda} \) signal sample with the product of a Novosibirsk function in \( m_{ES} \) and a sum of two Gaussian functions \( f^G \) in \( m(D^0\Lambda \bar{\Lambda}) \). The Novosibirsk function is defined as

\[
f^{\text{Novo}}(m_{ES}) = \exp \left[ -\frac{1}{2} \left( \frac{\ln^2 [1 + 2\alpha m_{ES} - \mu]}{\alpha^2} + \alpha^2 \right) \right],
\]

\[
\lambda = \sinh(\alpha \sqrt{\ln 4})/(\sigma \alpha \sqrt{\ln 4}),
\]

with \( \mu \) the mean value, \( \sigma \) the width, and \( \alpha \) the tail parameter. The decay \( \bar{B}^0 \rightarrow D^0\Sigma^0 \bar{\Lambda} \) is described by the product of a Novosibirsk \( f^{\text{Novo},1} \) function in \( m_{ES} \) and a sum of another Novosibirsk function \( f^{\text{Novo},2} \) and a Gaussian \( G \) in

![Dalitz plot for simulated \( D^0 \rightarrow K^-\pi^+\pi^0 \) events before (gray stars) and after (black crosses) the \( w_{\text{Dalitz}} > 0.02 \) requirement. Resonant decays are indicated.](image-url)

FIG. 2 (color online). Dalitz plot for simulated \( D^0 \rightarrow K^-\pi^+\pi^0 \) events before (gray stars) and after (black crosses) the \( w_{\text{Dalitz}} > 0.02 \) requirement. Resonant decays are indicated.
All parameters are determined using Monte Carlo simulated events and are fixed in the final fit. Background from \( e^+ e^- \rightarrow q\bar{q} \) events and other \( B \) meson decays is modeled by the product of an ARGUS function [23] in \( m_{\text{ES}} \) and a first order polynomial in \( m(D^0\Lambda\bar{\Lambda}) \).

The full fit function is defined as

\[
 f^\text{Fit}_j = f^\Lambda_j + f^{\Sigma^0}_j + f^{Bkg}_j \\
 = f^{\text{Novo},\Lambda}_j(m_{\text{ES}}) \times f^{GG}_j(m(D^0\Lambda\bar{\Lambda})) + f^{\text{Novo},\Sigma^0}_j(m_{\text{ES}}) \\
 \times [f^{\text{Novo},\Sigma^0}_j(m(D^0\Lambda\bar{\Lambda})) + G^{\Sigma^0}_j(m(D^0\Lambda\bar{\Lambda}))] \\
 + f^{\text{ARGUS},\Lambda}_j(m_{\text{ES}}) \times f^{\text{Poly},\Lambda}_j(m(D^0\Lambda\bar{\Lambda})),
\]

where the index \( j \) corresponds to the three \( D^0 \) decay modes.

The branching fraction is determined from

\[
 B(B^0 \rightarrow D^0\Lambda\bar{\Lambda}) = \frac{N(B^0 \rightarrow D^0\Lambda\bar{\Lambda})}{2 N_{\text{BG}}^0 \times \bar{e}} \times \frac{1}{B(\Lambda \rightarrow p\pi^0)^2 B(D^0 \rightarrow X)},
\]

where \( N(B^0 \rightarrow D^0\Lambda\bar{\Lambda}) \) is the fitted signal yield, \( N_{\text{BG}}^0 \) the number of the \( B^0\bar{B}^0 \) pairs assuming \( B(\Upsilon(4S)\rightarrow B^0\bar{B}^0) = 0.5 \), \( \bar{e} \) the average reconstruction efficiency, and \( B(\Lambda \rightarrow p\pi^0) \) and \( B(D^0 \rightarrow X) \) the branching fractions for the daughter decays of \( \Lambda \) and \( D^0 \), respectively. An analogous expression holds for \( B(\bar{B}^0 \rightarrow D^0\Sigma^0\Lambda) \). The average efficiency \( \bar{e} \) is defined as \( N_{\text{rec}} / N_{\text{gen}} \) using signal MC events, where \( N_{\text{rec}} \) is the number of reconstructed signal events after all cuts and \( N_{\text{gen}} \) the number of all generated events assuming a phase space distribution.

We perform a simultaneous fit of the three \( D^0 \) decay channels to obtain

\[
 N_\Lambda = \frac{N(B^0 \rightarrow D^0\Lambda\bar{\Lambda})}{e^1 B(D^0 \rightarrow X)}, \\
 N_{\Sigma^0} = \frac{N(\bar{B}^0 \rightarrow D^0\Sigma^0\Lambda)}{e^{20} B(D^0 \rightarrow X)}.
\]

The likelihood function is given by

\[
 L = \prod_j e^{-\bar{e} N_j B_j N_{\text{ES},j} f_j^\Lambda(m_{\text{ES},k}, m(D^0\Lambda\bar{\Lambda}))} \\
 \times \prod_k [\bar{e}_j B_j N_{\Lambda} f_j^\Lambda(m_{\text{ES},k}, m(D^0\Lambda\bar{\Lambda}))_k] \\
 + e_j^{\Sigma^0} B_j N_{\Sigma^0} f_j^{\Sigma^0}(m_{\text{ES},k}, m(D^0\Lambda\bar{\Lambda}))_k],
\]

where \( B_j \) is the branching fraction for the \( j \)th \( D^0 \) decay, \( N_{\text{BG},j} \) the number of combinatorial background events in the \( j \)th subsample, \( N_\Lambda \) and \( N_{\Sigma^0} \) the yields of \( B^0 \rightarrow D^0\Lambda\bar{\Lambda} \) and \( \bar{B}^0 \rightarrow D^0\Sigma^0\Lambda \), and \( \bar{e}_j^\Lambda \) and \( \bar{e}_j^{\Sigma^0} \) the average efficiencies for the \( j \)th \( D^0 \) decay.

V. SYSTEMATIC UNCERTAINTIES

We consider the following systematic uncertainties: the uncertainties associated with the number of \( BB \) events, the particle identification (PID) algorithm, the tracking algorithm, the \( \pi^0 \) reconstruction, the \( D^0 \) and \( \Lambda \) branching fractions, the efficiency correction, and the fitting algorithm.

The uncertainty associated with the number of \( BB \) pairs is 0.6%. We determine the systematic uncertainty associated with the PID by applying different PID selections and comparing the result with the nominal selection. The difference is 0.8%, which is assigned as the PID uncertainty. The systematic uncertainty associated with the tracking algorithm depends on the number of charged particles.
tracks in the decay. We assign a systematic uncertainty of 0.9% for the $D^0 \to K^- \pi^+$ and $D^0 \to K^- \pi^+\pi^0$ decays and 1.2% for the $D^0 \to K^- \pi^+\pi^-\pi^0$ decay. A 3% uncertainty is assigned to account for the $\pi^0$ reconstruction in $D^0 \to K^-\pi^+\pi^0$ decays. A detailed description of these detector-related systematic uncertainties is given in Ref. [18].

We rely on the known $D^0$ branching fractions in our fit. To estimate the associated systematic uncertainty we vary each branching fraction by one standard deviation of its uncertainty [1] and define the systematic uncertainty to be the maximum deviation observed with respect to the nominal analysis. We divide $m(\Lambda\Lambda)$ into six bins and determine the total reconstruction efficiency $\epsilon_i$ in each bin. We determine the uncertainty due to the use of the average efficiency $\bar{\epsilon}$ by studying $|\epsilon_i - \bar{\epsilon}|/\bar{\epsilon}$ as a function of $m(\Lambda\Lambda)$. We average these values and take the result of 16.3% ($D^0 \to K^-\pi^+$), 19.6% ($D^0 \to K^-\pi^+\pi^0$), and 16.8% ($D^0 \to K^-\pi^+\pi^-\pi^0$) as our estimate of the systematic uncertainty for the efficiency. We estimate the systematic uncertainty due to the fit procedure by independently varying the fit ranges of $m_{ES}$ and $m(D^0\Lambda\Lambda)$. The largest differences in the signal yield are 3.9% for the change of the $m_{ES}$ fit range and 2.1% for the change of the $m(D^0\Lambda\Lambda)$ fit range. To check our background model, we use a second-order polynomial in $m(D^0\Lambda\Lambda)$ instead of a first-order polynomial. The signal yield changes by 1.1%. We use an ensemble of simulated data samples reflecting our fit results to verify the stability of the fit. We generate 1000 such samples with shapes and yields fixed to our results and repeat the final fit. We find no bias in the signal-yield results. All systematic uncertainties are summarized in Table II.

The total systematic uncertainty, obtained by adding all sources in quadrature, is 20.1%.

TABLE II. Summary of the systematic uncertainties for $B^0 \to D^0 \Lambda\Lambda$.

| Source                          | Relative uncertainty |
|--------------------------------|----------------------|
| Additive uncertainty           |                      |
| Fit procedure                  | 4.6%                 |
| Multiplicative uncertainties   |                      |
| $B\bar{B}$ counting            | 0.6%                 |
| Particle identification        | 0.8%                 |
| Tracking                       |                      |
| $D^0 \to K^-\pi^+$             | 0.9%                 |
| $D^0 \to K^-\pi^+\pi^0$        | 0.9%                 |
| $D^0 \to K^-\pi^+\pi^-\pi^0$   | 1.2%                 |
| $\pi^0$ systematics            |                      |
| $D^0 \to K^-\pi^+\pi^0$        | 3.0%                 |
| $D^0$ and $\Lambda$ branching fractions | 2.9%              |
| Variation over phase space     |                      |
| $D^0 \to K^-\pi^+$             | 16.3%                |
| $D^0 \to K^-\pi^+\pi^0$        | 19.6%                |
| $D^0 \to K^-\pi^+\pi^-\pi^0$   | 16.8%                |
| Total uncertainty              | 20.1%                |

VI. RESULTS

The one-dimensional projections of the fit are shown in Fig. 4. We find

$$N_\Lambda = 1880^{+560}_{-500},$$
$$N_{\Sigma^0} = 2870^{+1680}_{-1560}. \quad (8)$$

The statistical significance is calculated as $\sqrt{-2 \log L_0/L_S}$, where $L_0$ is the likelihood value for a fit without a signal component and $L_S$ is the likelihood value for the nominal fit. The statistical significance of the combined $B^0 \to D^0\Lambda\Lambda$ and $\bar{B}^0 \to D^0\Sigma^0\Lambda$ yields is 3.9 standard deviations ($\sigma$), while those of the individual $B^0 \to D^0\Lambda\Lambda$ and $\bar{B}^0 \to D^0\Sigma^0\Lambda$ results are $3.4\sigma$ and $1.2\sigma$, respectively. Multiplicative systematic uncertainties do not affect the signal significance. Additive systematic uncertainties affecting the significance are negligible in this analysis compared to the statistical uncertainty. We therefore quote the statistical significance as the global significance.

The branching fractions are

$$B(\bar{B}^0 \to D^0\Lambda\Lambda) = (9.8^{+2.9}_{-2.6} \pm 1.9) \times 10^{-6},$$
$$B(\bar{B}^0 \to D^0\Sigma^0\Lambda + B^0 \to D^0\Lambda\Sigma^0) = (15^{+5}_{-4} \pm 3) \times 10^{-6}, \quad (9)$$

where the first uncertainties represent the statistical uncertainties and the second the systematic uncertainties. As a cross-check of the method, independent fits to the three subsamples are performed. The results of each of these fits are consistent with each other and with the nominal combined fit.

Since the statistical significance for $B(\bar{B}^0 \to D^0\Sigma^0\Lambda + B^0 \to D^0\Lambda\Sigma^0)$ is low, a Bayesian upper limit at the 90% confidence level is calculated by integrating the likelihood function,

$$B(\bar{B}^0 \to D^0\Sigma^0\Lambda + B^0 \to D^0\Lambda\Sigma^0) < 3.1 \times 10^{-5}. \quad (10)$$

To investigate the threshold dependence, we perform the fit in bins of $m(\Lambda\Lambda)$ and examine the resulting distribution after accounting for the reconstruction efficiency and $D^0$ branching fractions. The results are shown in Fig. 5. No significant enhancement in the $B^0 \to D^0\Lambda\Lambda$ event rate is observed at the baryon-antibaryon mass threshold within the uncertainties, in contrast to $B^0 \to D^0 p\bar{p}$ decays, which do exhibit such an enhancement [8].

We compare our results for the $B^0 \to D^0\Lambda\Lambda$ and $\bar{B}^0 \to D^0\Sigma^0\Lambda$ branching fractions to theoretical predictions. The result we obtain for the $B^0 \to D^0\Sigma^0\Lambda$ branching fraction is consistent with the prediction of $B(\bar{B}^0 \to D^0\Sigma^0\Lambda + B^0 \to D^0\Lambda\Sigma^0) = (18 \pm 5) \times 10^{-6}$ from Ref. [11]. However, the obtained result for the $B^0 \to D^0\Lambda\Lambda$ branching fraction is larger than the prediction of $B(\bar{B}^0 \to D^0\Lambda\Lambda) = (2 \pm 1) \times 10^{-6}$ [11] by a factor of
$$B(\bar{B}^0 \to D^0 \Lambda \bar{\Lambda})_{\text{exp}} = 4.9 \pm 3.0. \quad (11)$$

We further determine

$$\frac{B(\bar{B}^0 \to D^0 \Sigma^0 \bar{\Lambda} + \bar{B}^0 \to D^0 \Lambda \bar{\Sigma}^0)}{B(\bar{B}^0 \to D^0 \Lambda \bar{\Lambda})} = 1.5 \pm 0.9, \quad (12)$$

which is in agreement with our assumption that all four modes $\bar{B}^0 \to D^0 \Lambda \bar{\Lambda}$, $\bar{B}^0 \to D^0 \Sigma^0 \bar{\Lambda}$, $\bar{B}^0 \to D^0 \Lambda \bar{\Sigma}^0$, and $\bar{B}^0 \to D^0 \Sigma^0 \bar{\Sigma}^0$ are produced at equal rates. For the ratio of branching fractions, we find

$$\frac{B(\bar{B}^0 \to D^0 \Lambda \bar{\Lambda})}{B(\bar{B}^0 \to D^0 \Lambda \bar{\Lambda})} = \frac{1}{10.6 \pm 3.7}, \quad (13)$$

using $B(\bar{B}^0 \to D^0 \bar{p} \bar{p}) = (1.04 \pm 0.04) \times 10^{-4}$ \cite{1}. This is in agreement with the expected suppression of 1/12 discussed in the Introduction.
VII. SUMMARY

We find evidence for the baryonic B decay $\bar{B}^0 \rightarrow D^0 \Lambda\bar{\Lambda}$. We determine the branching fraction to be $\mathcal{B}(\bar{B}^0 \rightarrow D^0 \Lambda\bar{\Lambda}) = (9.8^{+2.6}_{-2.1} \pm 1.9) \times 10^{-6}$ with a significance of 3.4$\sigma$ including additive systematic uncertainties. This is in agreement with the Belle measurement [13]. Within the statistical uncertainty, our results support either a moderate threshold enhancement or no enhancement at all. The result for the branching fraction is in agreement within 1.3 standard deviations with theoretical predictions based on measurements of $\bar{B}^0 \rightarrow D^0 p\bar{p}$ and with simple models of hadronization. We find no evidence for the decay $\bar{B}^0 \rightarrow D^0 \Sigma^0\Lambda$ and calculate a Bayesian upper limit at 90% confidence level of $\mathcal{B}(\bar{B}^0 \rightarrow D^0 \Sigma^0\Lambda + \bar{B}^0 \rightarrow D^0 \Lambda\Sigma^0) < 3.1 \times 10^{-5}$. This result is in agreement with the theoretical expectation.

ACKNOWLEDGMENTS

We are grateful for the extraordinary contributions of our PEP-II colleagues in achieving the excellent luminosity and machine conditions that have made this work possible. The success of this project also relies critically on the expertise and dedication of the computing organizations that support BABAR. The collaborating institutions wish to thank SLAC for its support and the kind hospitality extended to them. This work is supported by the U.S. Department of Energy and National Science Foundation, the Natural Sciences and Engineering Research Council (Canada), the Commissariat à l’Energie Atomique and Institut National de Physique Nucléaire et de Physique des Particules (France), the Bundesministerium für Bildung und Forschung and Deutsche Forschungsgemeinschaft (Germany), the Istituto Nazionale di Fisica Nucleare (Italy), the Foundation for Fundamental Research on Matter (The Netherlands), the Research Council of Norway, the Ministry of Education and Science of the Russian Federation, Ministerio de Ciencia e Innovación (Spain), and the Science and Technology Facilities Council (United Kingdom). Individuals have received support from the Marie-Curie IEF program (European Union), the A.P. Sloan Foundation (USA) and the Binational Science Foundation (USA-Israel).
