High order cut discontinuous Galerkin methods for hyperbolic conservation laws in one space dimension

Pei Fu,* Gunilla Kreiss *

Abstract

In this paper, we develop a family of high order cut discontinuous Galerkin (DG) methods for hyperbolic conservation laws in one space dimension. The ghost penalty stabilization is used to stabilize the scheme for small cut elements. The analysis shows that our proposed methods have similar stability and accuracy properties as the standard DG methods on a regular mesh. We also prove that the cut DG method with piecewise constants in space is total variation diminishing (TVD). We use the strong stability preserving Runge-Kutta method for time discretization and the time step is independent of the size of cut element. Numerical examples demonstrate that the cut DG methods are high order accurate for smooth problems and perform well for discontinuous problems.

Keywords: Hyperbolic conservation laws; Discontinuous Galerkin method; Cut element method; Stabilization; Condition number.

1 Introduction

In this paper, we will develop a high order cut discontinuous Galerkin (DG) method to solve one dimensional scalar hyperbolic conservation laws,

\[
\begin{aligned}
u_t + (f(u))_x &= 0, \quad x \in \Omega = (x_l, x_r), \quad t > 0, \\
u(x, 0) &= u_0(x),
\end{aligned}
\]

with inflow or periodic boundary condition. The DG method was first introduced in 1973 by Reed and Hill [26]. A breakthrough was made by Cockburn et al. in

*Division of Scientific Computing, Department of Information Technology, Uppsala University, 75237 Uppsala, Sweden. Email: pei.fu@it.uu.se, gunilla.kreiss@it.uu.se.
to solve hyperbolic conservation laws, coupled with Runge-Kutta method for time discretization and total variation bounded (TVB) nonlinear limiters to achieve non-oscillatory properties in the presence of strong shocks. DG methods have low dispersion and dissipation errors for hyperbolic problems and have broad applications in many areas. We refer to \cite{20, 16, 27} for more details.

Most applications based on DG methods are defined on fitted meshes. To achieve the full potential accuracy of a DG method the mesh quality needs to be high. This requirement can be problematic for problems posed on complicated domains and implies remeshing for problems on moving domains or moving interfaces. Typically the resulting mesh will contain small elements, which for time-dependent problems may lead to very severe time-step restrictions. Small elements or cells cause severe problems also for continuous element methods and finite volume methods. Examples of efforts to overcome these difficulties are the finite volume based h-box method, Helzel et al \cite{2, 1} and the recent stabilized DG method by Engwer et. al \cite{10}, where transport along the characteristics is explicitly taken into account. Many unfitted methods have also been developed, as for example the extended finite element method \cite{11}, immersed boundary methods \cite{22}, and unfitted finite element methods \cite{3}.

In unfitted finite element methods, the physical domain is immersed in a background mesh. A possible approach is to solve for all degrees of freedom corresponding to the smallest set of elements covering the physical domain. The weak forms defining the numerical scheme are defined on the physical domain. Thus, for each element integration will only be done over the part that intersects the physical domain. If the intersection is very small, this will result in ill-conditioning of the mass and stiffness matrices, and a very severe time-step restriction. There are two common approaches to overcome these problems. One is the cell merging (or agglomeration) \cite{18, 19, 23, 24, 25, 28}, where the small cut part is absorbed into a neighbour element by extending the basis functions of the neighbour element. The other common approach is to add ghost penalty stabilization terms to the weak form \cite{5, 15, 21, 32, 33}. Some efforts have been made to develop DG methods with ghost stabilization. Gürkan and Massing consider elliptic problems \cite{14} and stationary hyperbolic equations \cite{13}.

In this paper, we develop a family of cut DG methods with ghost penalty stabilization for first order hyperbolic problems. We consider linear and nonlinear scalar equations in one space dimension. Our scheme is based on the standard DG methods, which saves considerable implementational effort. We add stabilization terms on the interior interfaces between cut elements and their neighbours. We will analyse the stability and accuracy of the resulting cut DG method, and discuss how the stabilization terms effect the condition numbers and eigenvalues of the involved ma-
trices. For the linear advection equation we prove an accuracy result, which is a half order lower compared to the accuracy of the standard DG method. However, we will report numerical observations showing optimal accuracy, both for linear and nonlinear problems. We also prove the total variation diminishing (TVD) property of the cut DG scheme with piecewise constants in space and explicit forward Euler time discretization. We can not prove the TVD property for the mean value (TVDM) for the proposed method based on high order polynomial spaces. However, we have observed numerically that the total variation is bounded for high order polynomials and explicit time stepping for problems with smooth solutions, and for discontinuous solutions when we apply the TVD minmod limiter. On coarse meshes with one small cut element and meshes with more small cut elements, some oscillations are triggered when a discontinuity passes a cut element and its neighbours. By applying a more robust limiting near cut elements, which explicitly lowers the polynomial degree when non-smoothness is detected, these oscillations can be avoided.

This paper is organized as follows. We will introduce notation and definitions of spaces and projections in Section 2. The proposed cut DG method is given in Section 3 and we discuss how the stabilization terms effect the condition number of the mass matrix and the eigenvalues of spatial discretization matrices. The stability and a priori error estimate will be analysed in Section 4. Section 5 contains some numerical results. The paper is concluded with a summary and a brief discussion of how the proposed ideas can be extended to hyperbolic systems and higher dimensions.

2 Discrete spaces and projections

Let the computational domain be $\mathcal{T} = [x_L, x_R]$ partitioned by $x_L = x_{\frac{1}{2}} < x_{\frac{3}{2}} < \cdots < x_{N+\frac{1}{2}} = x_R$, which defines the background mesh in which the physical domain $\Omega = [x_l, x_r]$ is immersed. Let $I_j = [x_{j-\frac{1}{2}}, x_{j+\frac{1}{2}}]$ denote an element and $\mathcal{E}$ denote the set containing the edges in the background mesh. For simplicity, we assume all $I_j$'s have length $h$. Define the cut mesh as

$$\mathcal{T}_h = \{I_j \cap \Omega \neq \emptyset : j = 1, \cdots, N\}, \mathcal{T}_\Gamma = \{I_j \in \mathcal{T}_h | I_j \cap \Gamma \neq \emptyset\};$$

$$\mathcal{F}_h = \{F \in \mathcal{E} \cap \Omega\}, \mathcal{F}_\Gamma = \{F \in \mathcal{T}_h = I_j \cap I_k | I_j \in \mathcal{T}_\Gamma, d(I_j, \Gamma) < 0.5h, j \neq k\}.$$  \hspace{1cm} (2.1)

Here, $\Gamma$ is the boundary point $x_l$ or one or more interface points $x_p$, each of which cuts one background element into two cut elements and $d(I_j, \Gamma)$ denotes the cut size of the element $I_j$ cut by $\Gamma$. We will consider two settings. In the first, the boundary is immersed in the background mesh and the physical boundary point $x_l$ cuts the left
most element $I_1$ with the cut size $\alpha h$, $\alpha \in [0,1]$. We assume $\alpha \ll 1$, since this will be the difficult case. We have $\mathcal{T}_\Gamma = I_1$, $\mathcal{F}_\Gamma = x_{\frac{1}{2}}$.

![Figure 1: Discretization of the physical domain $\Omega$ and the computational domain $\mathcal{T}$](image)

In the second setting we consider problems with one or more interior interfaces, resulting in cut elements located in the interior part of the domain, see Figure 2. For each interface $x_p$ there are two cut elements with cut size $\alpha h$ and $(1-\alpha)h$, respectively, and the computational domain $\mathcal{T}$ is equal to $\Omega$. In this setting, $\mathcal{T}_\Gamma = I_j$, $\mathcal{F}_\Gamma = \{x_{\frac{1}{2}}\}$. The background element $I_J$ includes $[x_{\frac{1}{2}}, x_p]$ and $[x_p, x_{\frac{1}{2}}]$. Thus, $I_J$ will be used twice in the weak formulation as background element for both cut elements. Note that for the periodic problem, a boundary point can equivalently be taken as an interior point, and analyzing the mesh setting in Figure 1 suffices.

As for the standard DG method, we use the piecewise polynomial space

$$\mathcal{V}_h^r = \{v_h : v_h|_{I_j} \in P^r(I_j), \forall I_j \in \mathcal{T}_h\},$$

where $P^r(I_j)$ is the space of polynomials with degree at most $r$ in $I_j$. We note that the space $\mathcal{V}_h^r$ and basis functions of space $\mathcal{V}_h^r$ are defined on the background mesh. As usual, we define the average and the jump of a function $v$ at $x$ as

$$\{v\} = \frac{1}{2}(v^+ + v^-), \quad [v] = (v^+ - v^-).$$

For any $v \in \mathcal{V}_h^r$, $v^+ = \lim_{\epsilon \to 0^+} v(x + \epsilon)$ and $v^- = \lim_{\epsilon \to 0^+} v(x - \epsilon)$ denote the limit values of $v$ at $x$ from right and left. For square integrable functions on a given domain $K$, the
inner product and the $L^2$ norm are denoted

$$(v, w)_K := \int_K vwdx, \quad \|v\|_K := \sqrt{(v, v)_K}, \quad \forall v, w \in L^2(K). \quad (2.5)$$

3 The DG scheme

In this section, we will present the cut DG method for the scalar equation (1.1) with periodic boundary condition, on the mesh with one cut element on the left boundary, as in Figure 1. We will show how we stabilize and investigate how this affects the condition number and the eigenvalues of the matrices from the space discretization for the linear advection equation.

3.1 The cut DG scheme without stabilization

In this subsection, we use a methods of lines approach. We will discretize in space and give the semi-discrete DG method for the scalar hyperbolic equation (1.1). We multiply the equation (1.1) by the test function $v_h$ and integrate it by parts. Then we get the semi-discrete DG method which is to look for $u_h(\cdot, t) \in V_h^r$ such that for any $v_h \in V_h^r$ and for all $I_j \in \mathcal{T}_h$,

$$(u_h, v_h)_{I_j \cap \Omega} + \int_{I_j \cap \Omega} \frac{\hat{f}_j}{2} (v_{h, l}^-, v_{h, r}^+) - \int_{I_j \cap \Omega} (f(u_h), v_{x})_{I_j \cap \Omega} = 0. \quad (3.1)$$

Here $\hat{f}_j = \hat{f} (u_{h}^-(x, t), u_{h}^+(x, t))$ is numerical flux function to approximate flux $f(u)$ at the point $x$, and $x_l$ and $x_r$ denote the end points of $I_j \cap \Omega$ representing $x_l$ or $x_r \pm \frac{1}{2}$. As in the standard DG method [30], we use monotone fluxes which satisfies consistency: $\hat{f}(u, u) = f(u)$, continuity: $\hat{f}(u^-, u^+)$ is at least Lipschitz continuous with respect to both arguments, and monotonicity $\hat{f}(\uparrow, \downarrow)$: $\hat{f}(u^-, u^+)$ is a non-decreasing function of its first argument and a non-increasing function of its second argument. We sum the cut DG scheme (3.1) over $j$ and write it as

$$(u_h, v_h)_\Omega + a(u_h, v_h) = 0, \quad \forall v_h \in V_h^r, \quad (3.2)$$

$$a(u, v) = \sum_{j=1}^{N} (f(u), v_{x})_{I_j \cap \Omega}. \quad (3.3)$$

Next, we will consider the matrix form of the cut DG scheme (3.2) for the periodic linear advection equation with $f(u) = \beta u$ and $\beta > 0$ in (1.1)

$$u_t + (\beta u)_x = 0, \quad x \in (x_l, x_r), \quad t > 0. \quad (3.4)$$
Let \( \{ \phi_j^k \}^r_{k=0} \) be the basis of \( P^r \) on the element \( I_j \), and express \( u_h(\cdot, t) \in V_h^r \) as

\[
u_h \big|_{I_j} = \sum_{k=0}^r u_j^k(t) \phi_j^k(x), \quad (3.5)
\]

with \( u_j^k(t) \) being the unknown time-dependent coefficients of numerical solution \( u_h \).

Our implementation uses the orthogonal Legendre polynomials \( 1, \xi_j, \xi_j^2 - 1/3, \cdots \), with \( \xi_j = \frac{x - x_j}{h/2} \) as the basis functions in each element \( I_j \) and \( x_j \) denotes the centre point of \( I_j \). Thus, the local mass matrices on regular elements are diagonal, while they will be full on the cut elements because of the integration over only a part of the element. Introduce \( u_h \) (3.5) into the cut DG scheme (3.2) with the upwind flux \( \hat{f}(u_h^-, u_h^+) = \beta u_h^- \) for equation (3.4) with periodic boundary condition leads to the matrix form of the semi-discrete problem,

\[
\mathcal{M} U_t = S U, \text{ or } U_t = \mathcal{M}^{-1} S U. \quad (3.6)
\]

Here \( \mathcal{M} \) is the block-diagonal mass matrix, \( S \) is the stiffness matrix, and \( U \) is the coefficients vector of \( u_h \), which will be a smooth function of \( t \). The temporal stability of the semi-discrete scheme (3.2) depends on the eigenvalues of \( \mathcal{M}^{-1} S \). For (3.6) to be stable the eigenvalues of \( \mathcal{M}^{-1} S \) need to be in the negative half-plane. If this is satisfied, eigenvalues with large absolute values will set the time-step limit for explicit time-stepping methods. Also interesting is the mass matrix condition number, since ill-conditioning here may cause difficulties in time-stepping.

In Table 1, we show results for the domain \([0, 2]\) with a background mesh of 8 elements, where one cut element is located on the left boundary. We use \( \beta = 1 \) and consider \( \alpha = 10^{-2}, 10^{-10} \). Note that for the higher polynomial orders eigenvalues with positive real part appear as alpha goes to zero, which indicates instability. For lower orders eigenvalues of large magnitude appear, which cause severe explicit time-stepping limits. The results also indicate a sharply increasing condition number of the mass matrix, with the degree of the polynomials space, and as the size of the cut goes to zero. To overcome these problems, we will include stabilization.

### 3.2 The cut DG method with ghost penalty stabilization

In this subsection the starting point is a scaled version of the ghost penalty suggested in [21],

\[
j_1(u, v) = \sum_{F \in \mathcal{T}_1} \sum_{k=1}^r w_k h^{2k+1} \left[ \partial^k u \right]_F \left[ \partial^k v \right]_F. \quad (3.7)
\]
Table 1: Condition number of the mass matrix $M$ and the maximal absolute value and maximal real part of the eigenvalue $v_i$ of the spacial operator $(M^{-1}S)$ in the cut DG scheme without stabilization.

| degree | $\alpha = 10^{-2}$ | $\alpha = 10^{-10}$ |
|--------|-------------------|---------------------|
|        | $\mathcal{X}(M)$  | max(|$v_i$|) | $\mathcal{X}(M)$  | max(|$v_i$|) |
| $P^0$  | 1.00E+02 3.51E+02 | -3.51E+00 | 1.00E+10 3.50E+10 | -3.50E+00 |
| $P^1$  | 5.94E+06 8.59E+02 | -6.97E+00 | 1.31E+26 3.50E+10 | -6.96E+00 |
| $P^2$  | 7.48E+11 1.42E+03 | -9.25E+00 | 2.65E+26 5.72E+10 | 1.24E+10  |
| $P^3$  | 1.15E+17 2.05E+03 | -1.10E+01 | 2.34E+27 5.40E+12 | 5.40E+12  |

This stabilization is also suggested for a wave propagation problem in [33]. In this work we propose to use

$$J_s(u, v) = \sum_{F \in \mathcal{F}} \sum_{k=0}^r w_k h^{2k+s} \left[ \partial^k u \right]_F \left[ \partial^k v \right]_F.$$  (3.8)

to stabilize both mass and stiffness matrices. Compared to $j_1(u, v)$ (3.7) we have included the jump of $u$ to ensure that all terms are stabilized. With the stabilization $J_1(u_t, v)$ and $J_0(u, v)$, the semi-discrete cut DG scheme has the following form: look for $u_h(\cdot, t) \in \mathcal{V}_h$ such that for $v_h \in \mathcal{V}_h$,

$$(u_{h,t}, v_h) + \gamma_M J_1(u_{h,t}, v_h) + a(u_h, v_h) + \gamma_A J_0(u_h, v_h) = 0.$$  (3.9)

Here, $a(u, v)$ are defined in [33] and $\gamma_M, \gamma_A$ are positive constants. With $v_h = 1$ in (3.9), we get

$$\frac{d}{dt} \int_\Omega u_h dx + \hat{f}_{N+\frac{1}{2}} - \hat{f}_t = 0.$$  (3.10)

Thus, the cut DG scheme with stabilization $J_1(u_{h,t}, v_h)$ and $J_0(u_h, v_h)$ is globally conservative. We note that it is locally conservative for all elements which do not have a cut element as a neighbour, and for on all patches of elements that are connected by faces where the stabilization is applied.

Next, we study the eigenvalues and condition numbers of the matrices resulting from applying the stabilized cut DG scheme (3.9) to the linear advection equation (3.4) with parameter values $\gamma_M = 0.25, \gamma_A = 0.75$ and $\omega_k = \frac{1}{(2k+1)\Delta t^2}$ as in [33]. We write the scheme (3.9) with the periodic boundary condition in the matrix form as

$$\tilde{M} U_t = \tilde{S} U.$$  (3.11)

Here, $\tilde{M}$ is stabilized mass matrix with $\tilde{M} U_t = (u_{h,t}, v_h)_{\Omega} + \gamma_M J_1(u_{h,t}, v_h)$ and $\tilde{S}$ is stabilized stiffness matrix with $\tilde{S} U = -a(u_h, v_h) - \gamma_A J_0(u_h, v_h)$. In Table 2 the condition number of $\tilde{M}$, the maximal absolute value and the maximal real part of the eigenvalues of the spatial operator $(\tilde{M}^{-1}\tilde{S})$ are listed. Comparing the results in Table
and Table 1, the condition number of \( \tilde{M} \) is much smaller than for the original mass matrix. Besides, the maximal absolute eigenvalue and its real part from the stabilized scheme are almost the same as for the standard DG method on a uniform mesh in Table 3. We therefore expect similar time-step restrictions for the stabilized cut DG method as for the standard DG method. We have also tested the scheme with more small cut elements in the interior and get very similar results as in Table 2.

Table 2: Condition number of mass matrix \( \tilde{M} \) and maximal absolute value and maximal real part of the eigenvalue \( v_i \) of the spatial operator \( (\tilde{M}^{-1}\tilde{S}) \) in the cut DG scheme with stabilization.

| Degree | \( \alpha = 10^{-2} \) | \( \alpha = 10^{-10} \) |
|--------|-----------------|-----------------|
|        | \( \kappa(\tilde{M}) \) | \( \max(|v_i|) \) | \( \max(Re(v_i)) \) | \( \kappa(\tilde{M}) \) | \( \max(|v_i|) \) | \( \max(Re(v_i)) \) |
| \( P^0 \) | 6.53E+00 | 2.34E+01 | 3.47E-15 | 6.85E+00 | 2.45E+01 | -8.39E-17 |
| \( P^1 \) | 4.79E+01 | 2.22E+01 | 5.93E-16 | 5.07E+01 | 2.45E+01 | -2.56E-15 |
| \( P^2 \) | 3.77E+03 | 4.08E+01 | 1.12E-15 | 4.04E+03 | 4.11E+01 | 5.33E-16 |
| \( P^3 \) | 8.58E+05 | 6.69E+01 | 5.07E-15 | 9.39E+05 | 6.70E+01 | -2.53E-16 |
| \( P^4 \) | 1.93E+08 | 9.65E+01 | 4.34E-15 | 2.16E+08 | 9.67E+01 | -5.60E-16 |

In Figure 3, we plot the eigenvalues of \( \Delta t \tilde{M}^{-1}\tilde{S} \) from the stabilized cut DG scheme (3.9) for different polynomials and varying cut size with \( \alpha = 10^{-2}, 10^{-10} \). In our case the physical domain is \([0, 2] \), and in the cut cases the background mesh consists of 8 elements, of which two cut elements \([1, 1+\alpha h], [1+\alpha h, 1+h] \) are included as in Figure 2. The time steps are taken to be \( \Delta t = \lambda h \) with \( \lambda = 0.3, 0.2, 0.1, 0.1 \) for \( r = 1, 2, 3, 4 \in V_h^r \) polynomials, as for the standard DG method. From the results, we can observe that the eigenvalues are all located in the stable region of fourth order Runge-Kutta method. Thus, our proposed cut DG methods can use a similar time step as the standard DG method even with a very small cut cell.

Figure 3: The eigenvalue distributions \( v \) of \( \Delta t \tilde{M}^{-1}\tilde{S} \) from the cut DG scheme with different polynomial spaces \( P^r \) and \( \alpha = 10^{-2} \) (left), \( 10^{-10} \) (right) on the mesh setting in Figure 2.
3.3 Condition number of the mass matrix with stabilization

Without stabilization the mass matrix is a block diagonal matrix with $(r+1) \times (r+1)$ local stiffness matrices as diagonal blocks. For regular elements these blocks are diagonal. With the stabilization term, the mass matrix couples the degrees of freedom in cut elements with those of their neighbours. This coupling gives rise to a $2k(r+1) \times 2k(r+1)$ matrix with $k$ being the number of stabilized cut elements. Note that the global mass matrix $\tilde{M}$ is still block-diagonal but not element by element.

Following the analysis in [33], we can estimate the condition number of the mass matrix.

**Lemma 3.1.** The condition number of the modified mass matrix with stabilization $J_1(u_t, v)$ with $\gamma_M > 0$ has an upper bound

$$\kappa(\tilde{M}) \leq C_M \kappa(M). \quad (3.12)$$

Here, $M$ is the mass matrix for the standard DG scheme on a uniform mesh. For fixed $\gamma_M > 0$ and fixed weights $\omega_k$ the constant $C_M$ depends only on the polynomial order, and not on $h$ or $\alpha$. It will grow unboundedly if $\gamma_M$ approaches zero.

For details and proof of Lemma 3.1 we refer to the paper [33].

4 Analysis of the cut DG method with stabilization

In this section we analyze the stabilized cut DG scheme (3.9) with respect to stability and accuracy.

4.1 $L^2$ stability

We will use the entropy inequality in [17] to prove that the stabilized cut DG method (3.9) for periodic scalar hyperbolic problems is $L^2$ stable.

**Theorem 4.1.** With the parameters $\gamma_M \geq 0$, $\gamma_A \geq 0$ and flux $\hat{f}$ satisfying consistency, monotonicity and continuity, the semi-discrete cut DG scheme (3.9) for the periodic scalar hyperbolic equation (1.1) satisfies

$$||u_h(\cdot,t)||^2_\Omega + \gamma_M J_1(u_h(\cdot,t), u_h(\cdot,t)) \leq ||u_h(\cdot,0)||^2_\Omega + \gamma_M J_1(u_h(\cdot,0), u_h(\cdot,0)).$$

**Proof.** Taking $v_h = u_h(\cdot,t)$ in the scheme (3.9) we get

$$(u_{h,t}, u_h)_\Omega + \gamma_M J_1(u_{h,t}, u_h) + a(u_h, u_h) + \gamma_A J_0(u_h, u_h) = 0. \quad (4.1)$$
That is

\[ 0 = \int_{\Omega} u_{h,t} u_h dx + \gamma_M J_1(u_{h,t}, u_h) + \gamma_A J_0(u_h, u_h) + \sum_j \left( - \int_{I_j \cap \Omega} f(u_h)(u_h)_x dx + \tilde{f}_{j\delta} u_{h,j\delta}^+ - \tilde{f}_{j\delta} u_{h,j\delta}^- \right). \]  

(4.2)

We define \( G_j = - \int_{I_j \cap \Omega} f(u_h)(u_h)_x dx + \tilde{f}_{j\delta} u_{h,j\delta}^- - \tilde{f}_{j\delta} u_{h,j\delta}^+ \) and \( \tilde{F}(u) = \int^u f(u) du \).

Then, we have

\[ G_j = \left( - \tilde{F}(u_{h,j\delta}^-) + \tilde{f}_{j\delta} u_{h,j\delta}^- \right) - \left( - \tilde{F}(u_{h,j\delta}^+) + \tilde{f}_{j\delta} u_{h,j\delta}^+ \right) + \Theta_{j\delta}. \]

Here,

\[ \Theta_{j\delta} = - \tilde{F}(u_{h,j\delta}^-) + \tilde{f}_{j\delta} u_{h,j\delta}^- + \tilde{F}(u_{h,j\delta}^+) - \tilde{f}_{j\delta} u_{h,j\delta}^+. \]

By the mean value theorem it follows that

\[ \Theta = - \tilde{F}(u_{h}^-) + \tilde{f} u_{h}^- + \tilde{F}(u_{h}^+) \quad \text{and} \quad \tilde{F}(\uparrow, \downarrow) \]  

(4.3)

where \( \xi \) is a value between \( u_{h}^- \) and \( u_{h}^+ \), and the monotonicity \( \tilde{f}(\uparrow, \downarrow) \) as well as consistency \( f(\xi) = \tilde{f}(\xi, \xi) \) of flux function \( \tilde{f} \) are used. Thus, the equation (4.2) becomes

\[ 0 = \int_{\Omega} u_{h,t} u_h dx + \gamma_M J_1(u_{h,t}, u_h) + \gamma_A J_0(u_h, u_h) + \sum_j G_j \]

(4.4)

\[ = \int_{\Omega} u_{h,t} u_h dx + \gamma_M J_1(u_{h,t}, u_h) + \gamma_A J_0(u_h, u_h) + \sum_j \Theta_{j\delta}. \]

Here, \( \sum_j \left( - \tilde{F}(u_{h,j\delta}^-) + \tilde{f}_{j\delta} u_{h,j\delta}^- \right) - \left( - \tilde{F}(u_{h,j\delta}^+) + \tilde{f}_{j\delta} u_{h,j\delta}^+ \right) = 0 \) follows from the periodic boundary condition. With \( \gamma_M \geq 0 \) and \( \gamma_A \geq 0 \) in the stabilization we have

\[ \frac{1}{2} \frac{d}{dt} \left( \int_{\Omega} u_h^2 dx + \gamma_M J_1(u_h, u_h) \right) = \int_{\Omega} u_{h,t} u_h dx + \gamma_M J_1(u_{h,t}, u_h) \leq 0. \]  

(4.5)

Integrating this relation in time completes the proof.

Further, with \( \gamma_M > 0 \) Theorem 4.1 can be combined with Lemma 3.1 to yield a corresponding estimate for the coefficient vector \( |U(t)| = \sqrt{U^T U} \), which is independent of the cut size \( \alpha \). We point out that the semi-discrete cut DG scheme (3.1) without stabilization also satisfies \( L^2 \) stability, and that the terms \( J_1(u_{h,t}, v) \) and \( J_0(u, v) \) do not destroy the stability. Comparing with standard DG method, we can not have the cell entropy inequality in each cell because the stabilization terms combine the cut cells and their neighbours.
4.2 \textit{a priori} error estimate

In this subsection, we will derive an \textit{a priori} error estimate for the semi-discrete stabilized cut DG scheme \eqref{eq:cutDG} applied to the linear advection equation \eqref{eq:advection}. The projection $\pi_h^e$, which are stated in \cite{13}. The projection $\pi_h^e$ satisfies the following error estimates

\begin{align}
\|v - \pi_h^e v\|_{T_h,s} &\lesssim h^{r-s} \|v\|_{\mathcal{H}}, \quad 0 \leq s \leq r, \quad (4.6) \\
\|v - \pi_h^e v\|_{T_h,s} &\lesssim h^{r-s-1/2} \|v\|_{\mathcal{H}}, \quad 0 \leq s \leq r - 1/2, \quad (4.7) \\
\|v - \pi_h^e v\|_{T_h,s} &\lesssim h^{r-s-1/2} \|v\|_{\mathcal{H}}, \quad 0 \leq s \leq r - 1/2. \quad (4.8)
\end{align}

Here, the $\lesssim$ relation denotes $a \lesssim b \iff a \leq Cb$ with $C$ being some constant that is independent of $h$ and $r$. Further, $\| \cdot \|_{m,\mathcal{H}}$ denotes the usual norm of Sobolev spaces $H^m(\Omega)$ and $\| \cdot \|^2_{T_h,s} = \sum_{K\in T_h} \| \cdot \|^2_{s,K}$.

We assume $u(\cdot, t)$ is the exact solution of problem \eqref{eq:advection} and $u_h(\cdot, t) \in V_h$ is the approximate solution satisfying the cut DG scheme \eqref{eq:cutDG}. Thus, we have

\begin{equation}
(u_t, v_h)_\Omega + \gamma M J_1(u_t, v_h) + a(u, v_h) + \gamma A J_0(u, v_h) = 0, \quad \forall v_h \in V_h. \quad (4.9)
\end{equation}

Subtracting equation \eqref{eq:cutDG} from \eqref{eq:advection} yields for $\forall v_h \in V_h$

\begin{equation}
((u - u_h)_t, v_h)_\Omega + \gamma M J_1((u - u_h)_t, v_h) + a(u - u_h, v_h) + \gamma A J_0(u - u_h, v_h) = 0. \quad (4.10)
\end{equation}

Furthermore, we assume $u \in L^\infty ((0, t); H^{r+2}(\Omega))$ and $u_t \in L^\infty ((0, t); H^{r+1}(\Omega))$. Then, we have the following error estimate.

\begin{theorem}
We assume $u$ is a sufficiently smooth exact solution of the linear advection equation \eqref{eq:advection} with periodic boundary condition, and $u_h(\cdot, t) \in V_h$ \eqref{eq:cutDG} is the approximation satisfying the stabilized cut DG scheme \eqref{eq:cutDG}. Then, we have the \textit{a priori} error estimate

\begin{equation}
\|u(\cdot, t) - u_h(\cdot, t)\|^2_{\Omega} \leq C h^{2r+1}. \quad (4.11)
\end{equation}

Here, $C$ is a constant depending on final time $t$, on $u$ and its derivatives, and on parameters $\gamma_M, \gamma_A, \omega_k$ in the stabilization terms. In particular, it is independent of the size of the cut geometries.
\end{theorem}

\textbf{Proof.} Define $\eta = u - \pi_h^e u, \theta = \pi_h^e u - u_h$ and we have $\theta \in V_h$ which is a smooth function of $t$. Then, we can rewrite the error equation \eqref{eq:4.11} as

\begin{equation}
(\theta_t, v_h)_\Omega + \gamma M J_1(\theta_t, v_h) + a(\theta, v_h) + \gamma A J_0(\theta, v_h)
\end{equation}

11
\[-(\eta_t, v_h)_\Omega + \gamma_M J_1((\pi_h^e u)_t, v_h) - a(\eta, v_h) + \gamma A J_0(\pi_h^e u, v_h), \text{ for } \forall v_h \in V^e_h. \] (4.12)

Taking the test function \(v_h = \theta(\cdot, t)\) at a particular time \(t\) in equation (4.12), we have

\[
Lhs := (\theta_t, \theta) + \gamma_M J_1(\theta_t, \theta) + a(\theta, \theta) + \gamma A J_0(\theta, \theta)
\]

\[
= \frac{1}{2} \frac{d}{dt} (||\theta||^2_\Omega + \gamma M J_1(\theta, \theta)) + \gamma A J_0(\theta, \theta) + \frac{\beta}{2} [\theta]^2 t + \frac{\beta}{2} \sum_{j=2}^N [\theta]_{j-\frac{1}{2}}^2,
\]

\[
Rhs := -(\eta_t, \theta) + \gamma_M J_1((\pi_h^e u)_t, \theta) - a(\eta, \theta) + \gamma A J_0(\pi_h^e u, \theta)
\]

\[
= -(\eta_t, \theta) + \gamma_M J_1((\pi_h^e u)_t, \theta) + \gamma A J_0(\pi_h^e u, \theta)
\]

\[
- \left(-\beta \hat{\theta}^2 \right)_t - \sum_{j=2}^N \beta \hat{\eta}^2_{j-\frac{1}{2}} [\theta]_{j-\frac{1}{2}} - \sum_{j=1}^N (\beta \eta, \theta)_{t\gamma} \right).
\]

In the above two equations, we used \(\hat{\theta}_N + \frac{1}{2} = \hat{\theta}_t, \hat{\eta}_N + \frac{1}{2} = \hat{\eta}_t\) and \([\theta]_t = \theta(x_t^+, t) - \theta(x_t^-, t)\) based on the periodic boundary condition. Using Cauchy-Schwarz inequality, we obtain

\[
Rhs \leq \frac{1}{2} (||\eta||^2_\Omega + ||\theta||^2_\Omega + \gamma M J_1((\pi_h^e u)_t, (\pi_h^e u)_t) + \gamma M J_1(\theta, \theta) + \gamma A J_0(\pi_h^e u, \pi_h^e u))
\]

\[
+ \gamma A J_0(\theta, \theta) + \beta \left(\sum_{j=2}^N [\theta]_{j-\frac{1}{2}} + [\theta]_t^2 + \sum_{j=2}^N \hat{\eta}^2_{j-\frac{1}{2}} + \hat{\eta}^2_t + h^{-2}||\eta||^2_\Omega + h^2||\theta_x||^2_\Omega \right).
\]

Using the inverse inequality \(h||\theta_x||_\Omega \leq C||\theta||_\Omega\) and combining the above equations in this subsection, we can get

\[
\frac{d}{dt} (||\theta||^2_\Omega + \gamma M J_1(\theta, \theta))
\]

\[
\leq ||\eta||^2_\Omega + ||\theta||^2_\Omega + \gamma M J_1((\pi_h^e u)_t, (\pi_h^e u)_t) + \gamma M J_1(\theta, \theta) + \gamma A J_0(\pi_h^e u, \pi_h^e u)
\]

\[
+ \beta \sum_{j=2}^N \hat{\eta}^2_{j-\frac{1}{2}} + \beta \hat{\eta}^2_t + h^{-2}||\eta||^2_\Omega + h^2||\theta_x||^2_\Omega
\]

\[
\leq C_1 ||\theta||^2_\Omega + \gamma M J_1(\theta, \theta) + I + II + III + IV + V, \quad (4.13)
\]

where

\[
I = ||\eta||^2_\Omega, \quad II = \beta h^{-2}||\eta||^2_\Omega, \quad III = \gamma M J_1((\pi_h^e u)_t, (\pi_h^e u)_t),
\]

\[
IV = \gamma A J_0(\pi_h^e u, \pi_h^e u), \quad V = \beta \sum_{j=2}^N \hat{\eta}^2_{j-\frac{1}{2}} + \beta \hat{\eta}^2_t.
\]

Here, \(\eta_t = (u - \pi_h^e u)_t = u_t - \pi_h^e u_t\). Thus, based on the properties of \(\pi_h^e\) in (4.6) and assuming \(u \in L^\infty ((0, t); H^{r+2}(\Omega)), u_t \in L^\infty ((0, t); H^{r+1}(\Omega))\), we have

\[
I = ||\eta||^2_\Omega \leq ||\eta||^2_{5h} \leq Ch^{2r+2}||u_t||^2_{H^{r+1}(\Omega)}, \quad (4.14)
\]

12
\[ II = h^{-2} \beta \| \eta \|_{\Omega}^2 \leq h^{-2} \beta \| \eta \|_{\Gamma_h}^2 \leq C h^{2r+2} \| u \|_{H^{r+2}(\Omega)}^2. \] (4.15)

For the stabilization terms \( III, IV \), we use the trace property (4.7) and \( J_h(u, v_h) = 0 \) with \( u \) sufficiently smooth. Then, we can obtain

\[
\frac{1}{\gamma} IV = J_0(\pi_h^e u, \pi_h^e u) = J_0(\pi_h^e u - u, \pi_h^e u - u) = \sum_{F \in T_h} \sum_{k=0}^{r} \omega_k h^{2k} [\partial^k (u - \pi_h^e u)]^2_F
\]

\[
\leq 2 \sum_{F \in T_h} \sum_{k=0}^{r} \omega_k h^{2k} \| \partial^k (u - \pi_h^e u) \|_F^2
\]

\[
\leq C' \sum_{F \in T_h} \sum_{k=0}^{r} \omega_k h^{2k} h^{2(r+1) - 2k - 1} \| u \|_{H^{r+1}(\Omega)}^2 \leq C h^{2r+1} \| u \|_{H^{r+1}(\Omega)}^2.
\]

Similar to the analysis of the above inequality, we also have

\[
\frac{1}{\gamma} III = J_1((\pi_h^e u)_t, (\pi_h^e u)_t) \leq C h^{2r+2} \| u_t \|_{H^{r+1}(\Omega)}^2.
\] (4.16)

Using the trace inequality (4.7) and upwind flux \( \hat{\eta} = \eta^- \), we have

\[
V = \beta \sum_{j=2}^{N} \hat{\eta}_{j-\frac{1}{2}}^2 + \beta \hat{\eta}_h^2 \leq C h^{2r+1} \| u \|_{H^{r+1}(\Omega)}^2.
\] (4.17)

Combing the above inequalities (4.13)-(4.17), we can get

\[
\frac{d}{dt} (\| \theta \|_{\Omega}^2 + \gamma_M J_1(\theta, \theta)) \leq C_1 (\| \theta \|_{\Omega}^2 + \gamma M J_1(\theta, \theta)) + C_2 h^{2r+1}.
\] (4.18)

Thus,

\[
\frac{d}{dt} e^{-C_1t} (\| \theta \|_{\Omega}^2 + \gamma_M J_1(\theta, \theta)) \leq C_2 e^{-C_1t} h^{2r+1},
\] (4.19)

which can be integrated in time to yield

\[
\| \theta \|_{\Omega}^2 + \gamma_M J_1(\theta, \theta) \leq e^{C_1t} (\| \theta \|_{\Omega}^2 + \gamma_M J_1(\theta, \theta)) \big|_{t=0} + C_2 \int_0^t e^{C_1(t-\tau)} d\tau h^{2r+1}.
\] (4.20)

We note that the initialization of \( u_h \) is based on the stabilized \( L^2 \) projection \( \Pi_h u_0 \) [4] of the smooth initial data \( u_0(x) \). Thus, combing the property of projection \( \pi_h^e \) with the error estimation of stabilized \( L^2 \) projection \( \Pi_h \), we have

\[
\| \theta \|_{\Omega}^2 |_{t=0} \leq \| \pi_h^e u_0 - u_0 \|_{\Omega}^2 + \| u_0 - \Pi_h u_0 \|_{\Omega}^2 \leq C h^{2r+2},
\] (4.21)

\[
J_1(\theta, \theta) |_{t=0} \leq 2 (J_1(\pi_h^e u_0 - u_0, \pi_h^e u_0 - u_0) + J_1(u_0 - \Pi_h u_0, u_0 - \Pi_h u_0)) \leq C h^{2r+2}.
\]
Then, with initial error (4.21) and (4.20), we obtain

$$||\theta||^2_\Omega + \gamma_M J_1(\theta, \theta) \leq Ch^{2r+1}. $$

Finally, applying the triangle inequality and the property of projection $\pi^c_h$, we have the a priori error estimate (4.11).

Remark 4.3. Our estimate based on the projection $\pi^c_h$ yields lower accuracy than for the standard method. In Section 5, optimal accuracy is observed numerically.

4.3 TVD stability

In this subsection, we will prove that the stabilized cut DG scheme (3.9) with piecewise constants in space for the linear advection equation (3.4) with periodic boundary condition is TVD stable when the explicit Euler time discretization is applied. Let $u^n_j$ denote the solution $u_h(x, t_n)$ in the element $I_j \cap \Omega$. A DG scheme is TVD stable if it satisfies

$$TV (u^{n+1}_h) \leq TV (u^n_h), \quad \text{with } TV (u^n_h) = \sum_j |u_{j+1}^n - u_j^n|. \quad (4.22)$$

With the setting in Figure II we have the cut DG scheme (3.9) with piecewise constants in space and explicit Euler time discretization as

$$\begin{align*}
\alpha u_1^{n+1} + \gamma_M u_1^{n+1} - \gamma_M u_2^{n+1} = & \alpha u_1^n - \gamma_M u_2^n + \gamma_M u_1^n \\
+ & \lambda (u_N^n - u_1^n) + \lambda \gamma_A (u_2^n - u_1^n),
\end{align*} \quad (4.23)$$

$$\begin{align*}
u_2^{n+1} + \gamma_M u_2^{n+1} - \gamma_M u_1^{n+1} = & u_2^n - \gamma_M u_1^n + \gamma_M u_2^n \\
+ & \lambda (u_1^n - u_2^n) - \lambda \gamma_A (u_2^n - u_1^n),
\end{align*} \quad (4.24)$$

$$u_{j+1}^n = u_j^n + \lambda (u_{j-1}^n - u_j^n), \quad j = 3, \cdots, N. \quad (4.25)$$

Here, $\lambda = \Delta t/h$ is Courant number. For this scheme, we have the following theorem.

**Theorem 4.4.** The stabilized cut DG scheme (3.9) with piecewise constants in space and the explicit Euler time discretization for linear advection equation with $\beta = 1$ is TVD stable under the condition that the time step satisfies $\Delta t/h \leq \alpha + \gamma_M/\gamma_{M+1}$, and parameters satisfy $0 < \gamma_M \leq \gamma_A$ and $(1 + \alpha)\gamma_A - \gamma_M \leq 1 - \alpha$.

**Proof.** With the periodic boundary condition we define $u_0 = u_N$ and divide

$$\sum_{j=1}^N |u_j - u_{j-1}| = \sum_{j=3}^N |u_{j+1} - u_j| + |u_2 - u_1| + |u_3 - u_2| + |u_1 - u_N|. \quad (4.26)$$
We first consider $u_2^{n+1} - u_1^{n+1}$ by subtracting equation (4.23) from equation (4.24) multiplied by $\alpha$,

$$u_2^{n+1} - u_1^{n+1} = \left(1 - \frac{\alpha + \alpha \gamma_A + \gamma_A}{\alpha + \alpha \gamma_M + \gamma_M}\right) (u_2^n - u_1^n) + \frac{\lambda}{\alpha + \alpha \gamma_M + \gamma_M} (u_1^n - u_N^n).$$

Next, we compute $u_3^{n+1} - u_2^{n+1}$ by subtracting equation (4.24) from equation (4.25) with $j = 3$ and get

$$u_3^{n+1} - u_2^{n+1} = \gamma_M (u_2^{n+1} - u_1^{n+1}) + (1 - \lambda) (u_3^n - u_2^n) + (\lambda + \lambda \gamma_A - \gamma_M) (u_2^n - u_1^n).$$

Replacing $u_2^{n+1} - u_1^{n+1}$ in equation (4.27) by equation (4.26), we have

$$u_3^{n+1} - u_2^{n+1} = \lambda \frac{\alpha + \alpha \gamma_M + \gamma_A}{\alpha + \gamma_M + \gamma_M} (u_2^n - u_1^n) + (1 - \lambda) (u_3^n - u_2^n)$$

$$+ \frac{\lambda \gamma_M}{\alpha + \alpha \gamma_M + \gamma_M} (u_1^n - u_N^n).$$

Then, we consider $u_1^{n+1} - u_N^{n+1}$. By subtracting $\alpha$ times equation (4.25) with $j = N$ from equation (4.23), and replacing $u_2^{n+1} - u_1^{n+1}$ by equation (4.26), we obtain

$$u_1^{n+1} - u_N^{n+1} = \lambda \frac{\alpha + \alpha \gamma_M + \gamma_A}{\alpha + \gamma_M + \gamma_M} (u_2^n - u_1^n) + \left(1 - \lambda \frac{\gamma_M + 1}{\alpha + \alpha \gamma_M + \gamma_M}\right) (u_1^n - u_N^n)$$

$$- \lambda (u_{N-1}^n - u_N^n).$$

For the standard part with $4 \leq j \leq N$, we have

$$u_j^{n+1} - u_j^{n+1} = (1 - \lambda) (u_j^n - u_{j-1}^n) + \lambda (u_{j-1}^n - u_{j-2}^n).$$

Summing the absolute of equations (4.26), (4.28), (4.29) and (4.30), we get

$$\sum_{j=1}^N |u_j^{n+1} - u_j^{n+1}| \leq \left(1 - \frac{\lambda (\gamma_M + 1)}{\alpha + \alpha \gamma_M + \gamma_M} + \frac{\lambda (\gamma_M + 1)}{\alpha + \gamma_M + \alpha \gamma_M}\right) |u_1^n - u_N^n|$$

$$+ \left(1 - \lambda \frac{\alpha + \alpha \gamma_A + \gamma_A}{\alpha + \alpha \gamma_M + \gamma_M} + \frac{\lambda (\gamma_A - \gamma_M)}{\alpha + \alpha \gamma_M + \gamma_M} + \lambda \frac{\alpha + \gamma_M + \alpha \gamma_A}{\alpha + \gamma_M + \alpha \gamma_M}\right) |u_2^n - u_1^n|$$

$$+ \sum_{j=3}^N |u_j^n - u_{j-1}^n|.$$

In the above inequality, the parameters $\gamma_M \geq 0, \gamma_A \geq 0$ and $0 < \lambda \leq 1$ are used. With $\gamma_M \leq \gamma_A$ and $(1 + \alpha) \gamma_A - \gamma_M \leq 1 - \alpha$, we have $\lambda \frac{\alpha + \alpha \gamma_A + \gamma_A}{\alpha + \alpha \gamma_M + \gamma_M} \leq \lambda \frac{\gamma_M + 1}{\alpha + \alpha \gamma_M + \gamma_M} \leq 1$ under the time step satisfying $\lambda = \frac{\Delta t}{h} \leq \alpha + \frac{\gamma_M}{\gamma_M + 1}$. Thus, we have

$$1 - \frac{\lambda (\gamma_M + 1)}{\alpha + \alpha \gamma_M + \gamma_M} \geq 0, 1 - \lambda \frac{\alpha + \alpha \gamma_A + \gamma_A}{\alpha + \alpha \gamma_M + \gamma_M} \geq 0, \gamma_A - \gamma_M \geq 0.$$
and we can get
\[
\sum_{j=1}^{N} |u_{j}^{n+1} - u_{j-1}^{n+1}| \leq \sum_{j=3}^{N} |u_{j}^{n} - u_{j-1}^{n}| + |u_{1}^{n} - u_{N}^{n}| + |u_{2}^{n} - u_{1}^{n}| = \sum_{j=1}^{N} |u_{j}^{n} - u_{j-1}^{n}|.
\]

As for the standard DG scheme, we can not get the TVD stability for higher order polynomials. Similar to the standard DG method, we use the TVB \textit{minmod} limiter \cite{8} to control the oscillations and overshoot produced from the stabilized cut DG scheme \cite{3.9}. We define the cell average of the solution \(u\) as
\[
\overline{u}_{j} = \frac{1}{|I_{j} \cap \Omega|} \int_{I_{j} \cap \Omega} u \, dx,
\]
and further define
\[
\tilde{u}_{j} = u_{j+\frac{1}{2}} - \overline{u}_{j}, \quad \tilde{\tilde{u}}_{j} = u_{j} - u_{j-\frac{1}{2}}, \quad \Delta_{+} \overline{u}_{j} = \overline{u}_{j+1} - \overline{u}_{j}, \quad \Delta_{-} \overline{u}_{j} = \overline{u}_{j} - \overline{u}_{j-1}.
\]

We modify both \(\tilde{u}_{j}\) and \(\tilde{\tilde{u}}_{j}\) by the TVB \textit{minmod} limiter \(\tilde{m}\),
\[
\tilde{u}_{j}^{(\text{mod})} = \tilde{m} \left( \tilde{u}_{j}, \Delta_{+} \overline{u}_{j}, \Delta_{-} \overline{u}_{j} \right), \quad \tilde{\tilde{u}}_{j}^{(\text{mod})} = \tilde{m} \left( \tilde{\tilde{u}}_{j}, \Delta_{+} \overline{u}_{j}, \Delta_{-} \overline{u}_{j} \right).
\]

For the definitions of function \(\tilde{m}\) and details of the TVB limiter, we refer to \cite{8}. Then we recover the limited function \(u_{h}^{(\text{mod})}\) by maintaining the old cell average \(\tilde{u}_{j}\) and the new point values given by \(u_{h}^{(\text{mod})} \left( x_{j+\frac{1}{2}}^{-} \right) = \tilde{u}_{j} + \tilde{u}_{j}^{(\text{mod})}\), \(u_{h}^{(\text{mod})} \left( x_{j-\frac{1}{2}}^{+} \right) = \tilde{\tilde{u}}_{j} - \tilde{\tilde{u}}_{j}^{(\text{mod})}\). This recovery is unique for \(P^{k}\) polynomials with \(k \leq 2\). When \(k > 2\), the recovery is done by setting high order coefficients to zero.

Note that we can not prove the TVDM property of the stabilized cut DG scheme with high order polynomials. The reason is the jump of high order derivatives in the stabilization \(J_{s}(u_{h}, v)\). However, we observe numerically that the stabilized cut DG scheme is TVB when the limiter is applied. On coarse meshes with one small cut element and meshes with more small cut elements, some oscillations are triggered when a discontinuity passes a cut element and its neighbours. In Appendix B, we describe a modified limiting procedure, where the approximation is locally reduced to the \(P^{0}\) scheme in a cut element and its neighbours when the standard limiter indicates that limiting is needed in a cut element or its neighbour.

5 Numerical examples

In this section, we present numerical examples that demonstrate the performance of our proposed stabilized cut DG scheme \cite{3.9} for scalar problems \cite{1.1}. Based on
the numerical studies for eigenvalues of the spatial operator in Section 3 and the
analysis in Section 4 we include both stabilization terms $J_1(u_t, v)$ and $J_0(u, v)$ with
coefficients $\gamma_M = 0.25, \gamma_A = 0.75, \omega_k = \frac{1}{(2k+1)k}$. Both linear and nonlinear cases are
considered. In all our computations, the third order TVD RK method [12] is used
when $r \leq 2$, and the fourth order five stages RK method is used when $r = 3$ for the
time discretization. We use a time step $\Delta t = \lambda h$, where the Courant number $\lambda$ varies
with polynomial order. We consider the case with a cut element at the boundary, see
Figure 1 and cases with one or more cut elements in the interior, see Figure 2. In
the problems with non-smooth solutions, limiting is used to control oscillations.

5.1 Accuracy test for the linear case

In this subsection, we consider the one dimensional linear advection equation and
periodic boundary condition,

$$u_t + u_x = 0, \ 0 < x < 2, \ t > 0, \quad (5.1)$$

with the initial data $u(x, 0) = 1.0 + 0.5 \sin(\pi x)$. The exact solution is $u(x, t) =
1 + 0.5 \sin(\pi(x - t))$. We test the problem (5.1) on the mesh setting in Figure 1
with one cut element on the left boundary. The computational domain $[x_L, x_R] =
[x_l - (1 - \alpha)h, x_r]$ with $\alpha \in (0, 1]$ and $h$ the regular size of interior elements. In
our test, $\Delta t = \lambda h \frac{x_r - x_l}{N + \alpha - 1}$ with $N = 40, 80, 160, 320, 640$ and $\lambda = 0.5, 0.3, 0.2, 0.14$ for
$r = 0, 1, 2, 3$ respectively. The stabilized cut DG scheme (3.9) with upwind flux is
applied up to time $t = 1$. In Figure 4 we plot $L^2$ and $L^\infty$ errors of the numerical
solutions on the mesh with a cut element of size $\alpha = 10^{-4}$ and the corresponding
average convergence rates are shown in the legend. Note that the stabilized cut DG
schemes are stable and converge optimally with the same Courant number $\lambda$ as the
standard DG scheme. We have also tested this problem on the mesh in Figure 2
and with $\alpha$’s as small as $10^{-10}$. In all cases the results are very similar.

5.2 The linear case with non-smooth data

In this subsection, we consider the linear advection problem $u_t + u_x = 0$ with non-
smooth initial data and a non-smooth boundary condition. We have tested many
more $\alpha$ values than those presented, and the solutions behave similarly for all $\alpha$
values.
Figure 4: $L^2$ and $L^\infty$ errors for the stabilized scheme (3.9) of different polynomial orders for the advection problem (5.1) at $t = 1$. The average convergence rate is given in the legend.

5.2.1 Non-smooth initial data

Here, we test the advection problem (5.1) with periodic boundary condition on domain $\Omega = [0, 1]$ and non-smooth initial data

$$u(x, 0) = \begin{cases} 
1 & 0.1 < x < 0.5, \\
0 & \text{otherwise.} 
\end{cases} \quad (5.2)$$

We use a mesh partition with equal size $h = (x_r - x_l)/N$, with the middle element $[0.5, 0.5+h]$ split into two cut elements $[0.5, 0.5+\alpha h], [0.5+\alpha h, 0.5+h]$ with $\alpha = 10^{-4}$, as in Figure 2. We first solve this problem using the cut DG scheme (3.9) with $P^0$ approximation and upwind flux, and the Courant number $\lambda = 0.2$. The stabilization is added only on the interior interface point $x = 0.5$ since $\alpha < 0.5$. In Figure 5 (a), we show the solution based on $P^0$ cut DG scheme. We do not observe any overshoots from our stabilized cut DG scheme. This is expected by the TVD stability.

To show the performance of the high order cut DG scheme, we also test this problem with $P^1$ polynomial space and $\alpha = 10^{-4}, \lambda = 0.3$. In Figure 5 (b)-(d), we show the numerical solution $u_h$ and the total variation of the mean values $TV(\bar{u}_h)$ of $u_h$ for different element sizes. We can see that on the coarsest mesh the numerical solution has an overshoot near the cut element and that $TV(\bar{u}_h)$ decreases after the discontinuity passes through the cut element. On the finer meshes we have not seen any overshoots. In the Figure 5 (d), we also study the performance of the stabilized DG scheme in a long time simulation. Note that there are many small increases in total variation $TV(\bar{u}_h)$ (red line) when the standard limiting is applied, each such increase decays rapidly with time and $TV(\bar{u}_h)$ remains bounded. We believe the overshoots may be caused by the higher derivative terms in the stabilization term $J_s(u, v)$. With the modified limiting described in appendix B, the results improve, see
Figure 5 (c). There are no overshoots even on the coarsest mesh, and \(TV(\bar{u}_h)\) (green line in (d)) is diminishing monotonically. Comparing with the standard DG method (blue line in (d)), we note that our proposed cut DG methods are more dissipative. We note that \textit{limiter} and \textit{modified} in the legend of figures mean the standard limiting and modified limiting is applied to the scheme, respectively.

Figure 5: Numerical solutions for the advection equation with non-smooth initial data at \(t = 0.3\) (a-c), and \(TV(\bar{u}_h)\) as function of \(t\) (d). Results are for one small cut element with \(\alpha = 10^{-4}\).

5.2.2 Non-smooth boundary data

Next, similar to computations in [34], we test the advection equation (5.1) on the physical domain \([x_l, x_r] = [0, 2]\) with the left boundary condition being

\[
g(t) = \begin{cases} 
0, & t \leq 1, \\
-1, & t > 1.
\end{cases}
\]  

(5.3)

We solve this example by the stabilized cut DG scheme (3.9) with \(P^2\) polynomials and upwind flux. Here the time step is \(\Delta t = 0.2h\) with \(h = (x_r - x_l)/(N + 1 - \alpha)\).
We use the mesh setting in Figure 1 with a cut element with $\alpha = 10^{-2}$ located on the left boundary. From the results in Figure 6 we can observe that the cut DG scheme with sufficient mesh refinement can simulate this problem well and capture the discontinuity. However, also for this case, we observe undershoots on coarse meshes. These decay with time after the discontinuity passes the cut element. The phenomena is not seen on fine meshes.

5.3 Nonlinear case: Burgers’ equation

In this subsection, we apply the high order stabilized cut DG scheme (3.9) with Godunov flux to the Burgers’ equation

$$u_t + \left(\frac{u^2}{2}\right)_x = 0, \quad x \in [x_l, x_r], \quad t > 0. \quad (5.4)$$

In these computation we used Courant number $\lambda = \alpha + \frac{2\gamma}{\gamma M + 1}, 0.3, 0.2, 0.1$ for polynomial spaces $P^r$ with $r = 0, 1, 2, 3$, respectively. In all computation for Burgers’ equation, we use the mesh setting in Figure 2 with many cut elements located in an interval in the central part of the domain. The cut elements are created by splitting each regular element in the interval into one small cut element of size $\alpha_k h$ and another of size $(1 - \alpha_k) h$. Here $\alpha_k = s\alpha$ with $\alpha = 10^{-4}$ and $s$ a random number in $[0.01, 1]$. 

5.3.1 Smooth initial data

We first test the Burgers’ equation (5.4) with smooth initial data $u_0(x) = \sin(\pi x), x \in [0, 2]$ and periodic boundary condition. This problem has a known solution, which
we use as a reference when computing errors. The solution is initially smooth, but at \( t = \frac{1}{\pi} \) a shock forms at \( x = 1 \). We compute the problem for accuracy until time \( t = 0.2 \), which is before the shock appears. The uniform meshes with \( N = 40, 80, 160, 320, 640 \) elements are used as the background mesh. The cut elements are located in \([0.75, 1.25]\) with \( N/4 \) small cut elements. In Figure 7 the errors are shown and the slope of the error lines are given in the legend for \( r = 0, 1, 2, 3 \). Observe that our method has optimal accuracy also in this case. We also ran this problem with more small cut elements, located on \([0.5, 1.5]\), with very similar result.

Figure 7: \( L^2 \) and \( L^\infty \) errors of \( u_h \) from scheme (3.9) on the mesh with \( \alpha = 10^{-4} \) and cut elements in \([0.75, 1.25]\) for the Burgers’ equation (5.4) with periodic boundary condition at \( t = 0.2 \).

Next we solved the Burgers’ equation with \( P^2 \) approximation with cut elements in \([0.75, 1.25]\) until time \( t = 0.5 \), when the shock has been formed. Results for \( h = 1/40, 1/160 \) (corresponding to 20, 80 small cut elements) with standard and modified limiting are shown in the Figure 8. With standard limiting there are some overshoots and oscillations near the shock and at the cut elements. With the modified limiting in Appendix B, there are no such artefacts.

### 5.3.2 Riemann problems

Consider Burgers’ equation (5.4) with initial data

\[
  u_0(x) = \begin{cases} 
    u_l, & x \leq 0, \\
    u_r, & x > 0.
  \end{cases}
\]

We will use our proposed stabilized cut DG scheme (3.9) with the \( P^0 \) and \( P^1 \) approximations, and let all elements in \([-0.5, 0.5]\) be cut.

First we let \( u_l = -1 < 0 < u_r = 1 \). In this case, a rarefaction wave is the weak solution, which satisfies the entropy condition. We solve this problem up to time
Figure 8: The numerical solutions of Burgers’ equation (5.4) at $t = 0.5$, by the $P^2$ scheme (3.9), with standard (left) and modified (right) limiting. All elements in $[0.75, 1.25]$ are cut.

$t = 0.5$ with an outflow boundary condition on the left side and an inflow boundary on the right side. The results are shown in Figure 9. The cut DG scheme based on $P^0$ can simulate this rarefaction wave well. For the $P^1$ approximation, overshoots are observed near the contact points, $-0.5$ and $0.5$, when no limiter is applied. With the standard TVB limiter, these oscillations disappear. However, oscillations are instead introduced in cut elements inside the rarefaction. With the modified limiting, no oscillations are observed on any meshes we tested.

Next we consider the case with initial data $u_l = 1 > 0 > u_r = -0.5$, for which the exact solution has a shock moving with speed $v = 1/4$. We solve using our cut DG scheme based on $P^0$ and $P^1$ polynomials up to time $t = 0.5$ and $t = 4$. The results are shown in Fig 10. We can observe that the piecewise constant approximation can capture the shock, and we did not observe any overshoots or undershoots up to $t = 4$. For the $P^1$ approximation at $t = 0.5$, we observe some undershoots on the coarser meshes, which disappear when we apply the modified limiter. At time $t = 4$, the shock has passed all the cut elements as well as their neighbours, and we see no undershoots or oscillations even on the coarser meshes when standard limiting is applied.

6 Conclusions and future work

We have developed a stabilized cut DG method of different orders for scalar first order hyperbolic problems in one space dimension. To avoid severe time-step restrictions or temporal instability the method includes jump stabilization at element interfaces adjacent to cut elements. Theoretical results include $L^2$ stability for the semi-discrete
Figure 9: Numerical solutions at \( t = 0.5 \) for the Burgers' equation Riemann problem with a rarefaction solution, based on \( P^0 \) or on \( P^1 \), with different limiting options. The figures to the right are magnifications of the left figures. All elements in \([-0.5, 0.5]\) are cut.

Figure 10: Numerical solutions of the Burgers' equation Riemann problem with a shock wave solution, based on \( P^0 \) or on \( P^1 \) with different limiting options. All elements in \([-0.5, 0.5]\) are cut. Left: \( t = 0.5 \), right: \( t = 4 \).
method independently of how small the cut elements are, and an accuracy result for the linear problems, based on the unfitted $L^2$ projection. For discontinuous solutions TVD stability is essential, and we prove that the stabilized cut DG method based on piecewise constants is TVD. From an analysis of the eigenvalues of the spatial discretization, we expect similar Courant numbers as for the standard DG method.

Numerical experiments further investigate the properties of the methods, and demonstrate several important features. A first result is that the CFL conditions for our cut DG methods are very similar to the CFL conditions of the corresponding standard DG methods. Secondly, a series of computations demonstrate that for smooth solutions we obtain optimal accuracy, even though the corresponding theoretical result is weaker by half an order. Thirdly, we could observe the TVB property numerically when a TVB or a TVD limiter is applied to our scheme. With standard limiting overshoots are observed as a discontinuity or shock passes a cut element or its neighbours, when higher order polynomials are used. Finally, we propose a modified limiting procedure involving the stabilization, which removes these artefacts.

The analysis and computations presented here can be extended to problems with interfaces where coefficients change abruptly. Of particular importance are the conservation properties at such interfaces, and we have started the investigation, and will present results elsewhere. Further analysis also includes investigating more robust limiters to control oscillations on the cut elements and if a cut element and the corresponding stabilization introduces extra dissipation, compared to the standard DG method. The cut DG method in this paper will also be extended to systems and to multiple dimensions in future work. We plan to consider standard cartesian elements, which are allowed to be arbitrarily cut by boundaries and/or interfaces, together with ghost stabilization for both mass and stiffness matrix. We expect, as for second order wave equations (see [33]), that the approach will yield $L^2$ stability, high order accuracy, and reasonable CFL-numbers also for systems, and for problems in multiple space dimensions. The positive experience reported in this paper, of applying standard DG techniques, gives reason to believe that the approach can also be applied to the extensions.

A The condition numbers and eigenvalues from standard DG method

In Table 3 we give the condition number of mass matrix $M$, and maximal absolute value and maximal real part of the eigenvalue $\lambda_i$ of the spatial operator $(M^{-1}S)$ from
the standard DG scheme. It is used to compare the results from the stabilized cut DG scheme.

Table 3: Condition number of mass matrix $M$ and maximal absolute value and real part of the eigenvalue $v_i$ of the spatial operator $(M^{-1}S)$ in the standard DG scheme on the uniform mesh without cut elements (N=7 elements on the domain $[0, 2]$).

| degree | $|\mathcal{K}(M)|$ | $\max(|v_i|)$ | $\max(Re(v_i))$ |
|--------|-----------------|-----------------|-----------------|
| $P^0$  | 1.00E+00        | 6.82E+00        | 1.04E-15        |
| $P^1$  | 3.00E+00        | 2.10E+01        | 2.60E-16        |
| $P^2$  | 1.13E+01        | 4.11E+01        | 2.60E-15        |
| $P^3$  | 4.38E+01        | 6.70E+01        | 9.26E-16        |
| $P^4$  | 1.72E+02        | 9.67E+01        | -1.18E-15       |

## B Modified limiting for the total variation stability

In this appendix, we describe a modified stabilized cut DG scheme for problems with discontinuities. For simplification, the forward Euler method is used to present the scheme. Starting with $u_h^n$ compute $u_h^{n+1}$ by the following steps.

- The minmod limiter is used as an indicator to check if the cut element or its neighbours are near a discontinuity or not.

- If no, we use the stabilized cut DG scheme without modification to update the solution $u_h^{n+1}$.

- If yes, the cut element or its neighbour needs to be limited and we define the limited solution $u_h^{(\text{mod})}|_{I_J} = \bar{u}_h|_{I_J}$. Then, we modify the stabilization and polynomial space in the stabilized cut DG scheme with $P^0$ approximation on the cut element and its neighbour elements which need be stabilized, which is

$$
\int_{I_J} u_h^{n+1} v dx + \gamma_M h [u_h^{n+1}]_{I_J} v_{I_J} = \int_{I_J} u_h^{\text{mod},n} v dx + \gamma_M h [u_h^{\text{mod},n}]_{I_J} v_{I_J}
$$

$$
- \hat{f}(u_h^{\text{mod},n}(x_{Jr}, t)) v_{Jr} + \hat{f}(u_h^{\text{mod},n}(x_{Jl}, t)) v_{Jl} - \gamma_A [u_h^{\text{mod},n}]_{I_J} v_{I_J}, \forall v \in V_h^0,
$$

$$
\int_{I_K} u_h^{n+1} v dx - \gamma_M h [u_h^{n+1}]_{I_K} v_{I_K} = \int_{I_K} u_h^{\text{mod},n} v dx - \gamma_M h [u_h^{\text{mod},n}]_{I_K} v_{I_K}
$$

$$
- \hat{f}(u_h^{\text{mod},n}(x_{Kr}, t)) v_{Kr} + \hat{f}(u_h^{\text{mod},n}(x_{Kl}, t)) v_{Kl}^{+}.
$$

25
\[ + \gamma_A [u_{h}^{\text{mod},n}]_{I_J} v_{I_J} - \int_{I_K} f(u_{h}^{\text{mod},n}) v dx, \forall v \in V_h^0. \]  

(B.1)

Here, \( I_J \) is the cut element. We assume \( I_K \) is its neighbour element which need to stabilized and \( x_{IJ} \) is the interior interface between \( I_J \) and \( I_K \).

- Update numerical solution \( u_{h}^{n+1} \). Here, \( u_{h}^{n+1} \) on elements \( I_J, I_K \) are constants and \( u_{h}^{n+1} \) is piecewise high order polynomial on the other elements.

We note that we just modify the stabilized cut DG scheme on the cut element and its neighbours when the limiting is needed at the cut element or its neighbours. It won’t change the scheme in the problems with continuous solution.
