Abstract
We propose an extension of the quantum entropy power inequality for finite dimensional quantum systems, and prove a conditional quantum entropy power inequality by using the majorization relation as well as the concavity of entropic functions also given by Audenaert et al (2016 J. Math. Phys. 57 052202). Here, we make particular use of the fact that a specific local measurement after a partial swap operation (or partial swap quantum channel) acting only on finite dimensional bipartite subsystems does not affect the majorization relation for the conditional output states when a separable ancillary subsystem is involved. We expect our conditional quantum entropy power inequality to be useful, and applicable in bounding and analyzing several capacity problems for quantum channels.

Keywords: entropy power inequality, partial swap operation, majorization relation, concavity of entropic function, conditional eigenvalues

(Some figures may appear in colour only in the online journal)

1. Introduction

The channel capacity of a channel (or communication system) in information theory is defined as the maximum rate at which information can be reliably transmitted through the given channel [1]. If we choose a communication system such as a quantum mechanical system or quantum channel, which models a quantum state transforming with its ancillary system (or
environment), and it is mathematically given by a completely positive, trace-preserving (CPT) map, we can naturally classify quantum, classical and private capacities over the quantum channel according to their respective input information sources [2, 3]. In general, determining the channel capacity of a quantum channel is not a simple problem in quantum information theory [4]. In particular, it is almost impossible to obtain a channel capacity when quantum entanglement is imposed [5], and most channel capacities are nonadditive [6–8]. However, one way to bound the capacity of any channel is to make use of the notion of the entropy power inequality (EPI), originally proposed by Shannon [1]. In quantum scenarios, EPIs have played a major role in bounding channel capacity for thermally noisy channels (see, for example, [9–11]). Furthermore, the concept of EPI is related to a fundamental mathematical isoperimetric inequality in classical as well as quantum regimes [12].

First, we briefly review Shannon’s statement of the entropy power inequality. The differential entropy for a (continuous) random variable $X$ of values $x \in \mathbb{R}^d$ with probability density function $p_X$ is defined as [1]

$$H(X) := - \int_{\mathbb{R}^d} p_X(x) \log p_X(x) d^d x,$$

which is the relevant information measure for the random variable $X$, and plays a central role in classical information theory. If the random variable $X$ takes a Gaussian distribution $\mathcal{N}_X$, we can obtain a variance $\frac{1}{2\pi} e^{2H(\mathcal{N})/d} = \nu(\mathcal{N}_X)$, which is usually called the entropy power or energy of the input random variable $X$. For convenience, we omit the factor $\frac{1}{2\pi}$ in the definition of the entropy power. Now, suppose that two independent random variables $X_1$ and $X_2$ on $\mathbb{R}^d$ are combined via the scaled addition rule or the (scaled) convolution operation ($*$); then, for a given output signal $X_1 \ast X_2$ at the end of the channel, we can find the following classical entropy power inequality (cEPI) [13, 14]:

$$\nu(X_1 \ast X_2) \geq t \nu(X_1) + (1 - t) \nu(X_2),$$

where $X_1 \ast X_2 = \sqrt{t}X_1 + \sqrt{1-t}X_2$ is the output signal under the convolution operation with a mixing parameter $t \in [0, 1]$. This expression can be restated as the following inequalities:

$$\exp \left( \frac{2H(Y)}{d} \right) \geq t \exp \left( \frac{2H(X_1)}{d} \right) + (1 - t) \exp \left( \frac{2H(X_2)}{d} \right),$$

or

$$H(Y) \geq tH(X_1) + (1 - t)H(X_2),$$

where $Y := X_1 \ast X_2$. Details of its proof can be found in several references (see [13–19]).

Recently, a quantum (Gaussian) version of the entropy power inequality, namely the quantum entropy power inequality (qEPI), has been proved [20, 21] and applied to several information-processing tasks [9, 22, 23]. The qEPI is a quantum analog (but not a direct generalization) of the cEPI, equipped with a $\tau$-transmissivity beamsplitter, simply $\tau$-BS known as the (Gaussian) quantum addition rule, and the constant $\kappa = \frac{1}{2}$ in the Gaussian case. Generally, the beamsplitter transformation with a parameter $\tau$ can be interpreted as a CPT map $G_\tau$ over two bosonic modes $\rho_x$, such that
where the beamsplitting operation is explicitly given by \( V_\tau := \sqrt{\tau} I + i\sqrt{1 - \tau} \sigma_x \) \(^5\) including the complex number \( i = \sqrt{-1} \). We note that \( I \) is an identity matrix and \( \sigma_x \) is the Pauli \( x \)-matrix, where the \( \tau \)-BS operation generally interpolates these two operators. Now, if we define \( \rho_\tau := \rho_x \boxtimes_\tau \rho_x \), then we know that qEPI, equation (3), has an entropic form of \( S(\rho_Y) \geq \tau S(\rho_X) + (1 - \tau)S(\rho_Z) \) for two independent inputs \( \rho_X \) and for the \( \tau \)-BS. By employing the quantum de Bruijn’s inequality and the entropy-scaling property known as ‘Gaussification’, we can obtain the entropic inequality [20] — the entropy of a channel’s mixed output is always increased.

A qEPI for \( d \)-dimensional quantum states (qudits) has also been proposed [24], and is given by the form of equation (3); but it is generally true when the constant \( \kappa \) is restricted to \( 0 \leq \kappa \leq \frac{1}{\log d} \), where \( d \approx 2D \). In the proof, the symmetric property and the concavity of the entropic function \( \nu_\kappa (\rho) \) in the region of \( \kappa \) via the majorization relation on a quantum state \( \rho \) was used. Furthermore, it is important to note that independent input quantum states for the quantum channel are represented by \( \rho_{X_i} \in D(C^d) \) with \( \ell \in \{1, 2\} \), where \( D(C^d) := \{ \rho \in B(C^d) : Tr \rho = 1, \rho = \rho^d \geq 0 \} \) is a class of density matrices on a bounded linear operator \( B(C^d) \) (over the \( d \)-dimensional Hilbert space), and those mixing operations with the parameter \( \tau \) are given by a partial swap as follows. We now review the partial swap operation \((p\text{-Swap})\) denoted by \( \boxtimes_\tau \), which is also known as the qudit addition rule [24]. For any \( \tau \in [0, 1] \) and any density matrices \( \rho_{X_i} \in D(C^d) \), we can find an output of the quantum channel via the \( p\text{-Swap} \) as

\[
\rho_{X_i} \boxtimes_\tau \rho_{X_j} = \mathbf{N}_\tau (\rho_{X_i} \otimes \rho_{X_j}) \\
= Tr_{X_j} \left[ U_\tau (\rho_{X_i} \otimes \rho_{X_j}) U_\tau^\dagger \right] \\
= \tau \rho_{X_i} + (1 - \tau) \rho_{X_j} - i \sqrt{\tau(1 - \tau)} [\rho_{X_i}, \rho_{X_j}],
\]

where \([A, B] = AB - BA\) is the commutator, the resulting state is also a \( d \)-level quantum state, and \( U_\tau := \sqrt{\tau} I + i\sqrt{1 - \tau} W \), where \( W \) is the swap operator such that \( W \rho_{AB} W^\dagger = \rho_{BA} \) on two \( d \)-level quantum systems. We call the map \( \mathbf{N}_\tau (\cdot) \) the partial swap channel on \( d \)-level quantum systems.

In this study, we prove a conditional version of the qEPI (CqEPI) for arbitrary \( d \)-level quantum states in section 3 through a conditional majorization relation (see section 2). We discuss our results and outline our future plans in section 4.

2. Conditional eigenvalues and majorization relation for quantum states

It was conjectured that, for any quantum states \( \rho_{X_i, X_E} \) and a mixing parameter \( \tau \in [0, 1] \),

\[
S(\rho_{X_i} \boxtimes_\tau \rho_{X_j} | \rho_E) \geq \tau S(\rho_{X_i} | \rho_E) + (1 - \tau)S(\rho_{X_j} | \rho_E),
\]

where the beamsplitting operation with \( \tau \) acts on any two quantum systems [25]. However, for any Gaussian product states—especially having the form \( \rho_{X_i E_i} \otimes \rho_{X_E E_S} \), Koenig proved that \( S(\rho_Y | \rho_E) \geq \tau S(\rho_X | \rho_E) + (1 - \tau)S(\rho_Z | \rho_E) \), where \( \rho_Y = \rho_{X_i} \boxtimes_\tau \rho_{X_j} \) and \( \rho_E = \rho_{E_i} \otimes \rho_{E_S} \) is the (separable) ancillary system. Koenig referred to this inequality as the conditional quantum EPI or CqEPI in the Gaussian regime. In his proof, Koenig exploits the quantum version of the ‘scaling property for the conditional entropy’ (lemma 6.2 in

---

\(^5\) If two input states are \( D \)-mode bosonic field quadratures with annihilation operators \( \hat{a}_j, \ldots, \hat{a}_D \) and \( \hat{\beta}_j, \ldots, \hat{\beta}_D \) respectively, then we can obtain the \( D \)-mode output quadrature as \( \forall j \in \{1, \ldots, D\}, \quad \hat{a}_j = \sqrt{\tau} \hat{a}_j + i\sqrt{1 - \tau} \hat{\beta}_j \).
and the 'conditional de Bruijn identity' (theorem 7.3, also in [25]) in the Gaussian regime. Recently, a similar result for the Gaussian CqEPI is introduced by de Palma and Trevisan [26]. In their papers, they have used quantum conditional entropy notation, \( S(\rho_A|\rho_B) = S(A|B)_{\rho_A\rho_B} := S(AB)_{\rho_A\rho_B} - S(B)_{\rho_B} \), which means the von Neumann entropy of system \( A \) when system \( B \) is conditioned. However, in this paper, we use a different notation of a set of conditional eigenvalues such as \( \lambda(\rho_A|B) \), given by any quantum measurement performed on the subsystem \( B \), so as to show another version of the CqEPI based on local measurements, which is not the same as the CqEPI with respect to the quantum conditional entropy. Our approach is related to the quantum discord, which represents another type of quantum correlation—different from entanglement [27–32].

The Gaussian CqEPI comes from the fact that, if any quantum state \( \rho_{XYE} \) has a conditionally independent form, i.e. \( \rho_{XYE} = \rho_{XE_1} \otimes \rho_{XE_2} \), then it can be decomposed as a direct sum with equality at \( n \). Then, for any \( \rho \), we use a different notation of the conditional version of the entropy power inequality. Here, we make use of the fact that any \( \rho \) is also obvious in the density operator formalism of the quantum regime [2].

Before the main proof, we briefly review the majorization condition for quantum states. Let \( \mathbf{m} = (m_1, m_2, \ldots, m_d) \) and \( \mathbf{n} = (n_1, n_2, \ldots, n_d) \) be vectors in \( \mathbb{R}^d \) with its components arranged in decreasing order of \( m_1 \geq m_2 \geq \cdots \geq m_d \) and \( n_1 \geq n_2 \geq \cdots \geq n_d \). Then, for any \( \mathbf{m} \) and \( \mathbf{n} \), \( \mathbf{m} \prec \mathbf{n} \) if, \( \forall k \in \{1, \ldots, d\} \), \( \sum_{j=1}^{k} m_j \leq \sum_{j=1}^{k} n_j \) with equality at \( k = d \). In addition, a function \( f : \mathbb{R}^d \rightarrow \mathbb{R} \) is called Schur concave, if \( f(\mathbf{m}) \geq f(\mathbf{n}) \) whenever \( \mathbf{m} \prec \mathbf{n} \) [34]. The majorization technique explained above is also obvious in the density operator formalism of the quantum regime [2].

By using the definition of the majorization condition above, and the partial swap channel in equation (5), it was proved in [24, 35] that, for any quantum states \( \rho_{X_1}, \rho_{X_2} \in D(\mathbb{C}^d) \), we can obtain
\[
\lambda(\rho_{X_1} \oplus \tau \rho_{X_2}) \prec \tau \lambda(\rho_{X_1}) + (1 - \tau) \lambda(\rho_{X_2}),
\]
for any \( \lambda(\rho) \) denotes a set of the eigenvalues for a quantum state \( \rho \), and \( \oplus \) the p-Swap operation with a mixing parameter \( \tau \in [0, 1] \). This point is crucial. Our main goal in this study is to extend equation (8) to the (measurement-based) conditional version for \( d \)-level quantum states.

3. CqEPI: main results

We now suggest that the \( p \)-Swap and its identity (theorem 1.1 in [35]) can be extended to a conditional version of the entropy power inequality. Here, we make use of the fact that any local measurements (LMSs) via the partial swap operation do not change the majorization condition when the separable environments \( E_1 \) and \( E_2 \) are measured locally (see figure 1 and lemma 1 below). Note that, if \( \rho_E \neq \rho_{E_1} \otimes \rho_{E_2} \), the CqEPI is still open as in equation (6).

---

6 The product quantum state introduced in [25, 33] also holds strong sub-additivity with the equality.
First, we briefly review the output states of the quantum channel through the partial swap operation. Let \( \rho_{\Psi E_1 E_2} := \rho_{\Psi E_1} \otimes \rho_{\Psi E_2} \) be the total quantum state. Then we have

\[
\rho_{\Psi E_1 E_2} = (N_\tau \otimes \mathbb{1}_{E_1 E_2})(\rho_{\Psi E_1 E_2}) = \text{Tr}_E (U_\tau \otimes \mathbb{1}_{E_1 E_2})(\rho_{\Psi E_1} \otimes \rho_{\Psi E_2})(U_\tau^\dagger \otimes \mathbb{1}_{E_1 E_2}),
\]

and also remember \( \rho_\tau = \rho_{\Psi X} \otimes \rho_{\Sigma} = N_\tau(\rho_{\Psi X} \otimes \rho_{\Sigma}) = \tau \rho_{\Psi X} + (1 - \tau) \rho_{\Sigma} - i\sqrt{\tau(1 - \tau)}[\rho_{\Psi X}, \rho_{\Sigma}] \). We now introduce a new set of eigenvalues of \( \rho_\Psi \) induced by \( \rho_{\Psi E_1 E_2} \) after local measurements on the separable environment \( \rho_{\Sigma E} \otimes \rho_{\Psi E_2} \), and we will use the notation such as \( \lambda(\rho_\Psi|E_1 E_2) \). Notice that the notation \( \rho_\Psi|E \) does not mean the conditional quantum state introduced in [36], but (as mentioned above) it is just a quantum state \( \rho_\Psi \) after a local measurement performed on the subsystem \( E \) for \( \rho_{\Sigma E} \). For example, if we choose a set of local measurements described by \( \{M_j\}_E \) on the subsystem \( \rho_{\Sigma E} \) (\( 1 \leq j \leq d_E \)), then we define

\[
\rho_{\Psi|E(j)} = \frac{1}{p_j} \text{Tr}_E \left( (\mathbb{1}_X \otimes M_j) \rho_{\Psi E}(\mathbb{1}_X \otimes M_j^\dagger) \right),
\]

where \( p_j = \text{Tr}(M_j^\dagger M_j \rho_{\Sigma E}) \) is the normalization factor. Thus, we can naturally define the set of conditional eigenvalues after a specific local measurement on \( E \) as follows: (\( \forall \rho_{\Sigma E} \))

\[
\lambda(\rho_{\Psi|E(j)}) := \lambda(\text{Tr}_E[(\mathbb{1}_X \otimes M_j) \rho_{\Psi E}(\mathbb{1}_X \otimes M_j^\dagger)]/p_j).
\]

As a subsidiary example, let us consider \( \rho_{\Psi E_1 E_2} = (N_\tau \otimes \mathbb{1}_{E_1 E_2})(\rho_{\Psi E_1} \otimes \rho_{\Psi E_2}) \), and a situation in which local projective measurements are involved. Let \( \{\psi_j\} \) and \( \{\phi_k\} \) be the local measurements on the environmental subsystems \( \rho_{\Sigma E_1} \) and \( \rho_{\Sigma E_2} \) respectively. Finally, to find the conditional eigenvalues, we define the final states (conditional outputs) after local measurements on the subsystems \( E_1 \) and \( E_2 \) as

\[
\sigma^{(j)}_{E_1} = \frac{1}{q^{(j)}_E} E_1(\psi_j|\rho_{\Sigma E_1} \psi_j)_E \quad \text{and} \quad \sigma^{(k)}_{E_2} = \frac{1}{q^{(k)}_E} E_2(\phi_k|\rho_{\Sigma E_2} \phi_k)_E \quad \text{where} \quad q^{(j)}_E = E_1(\psi_j|\rho_{\Sigma E_1} |\psi_j)_E\quad \text{and} \quad q^{(k)}_E = E_2(\phi_k|\rho_{\Sigma E_2} |\phi_k)_E.
\]

Figure 1. The setting for CqEPI on \( d \)-level quantum states (qudits). For any product input states in the form of \( \rho_{\Psi E_1} \otimes \rho_{\Sigma E_2} \), the diagram represents a quantum channel generating output of \( \rho_{\Psi_2} \otimes \rho_{\Sigma} \) for the quantum states. The unitary operation \( U_\tau \) corresponds to the \( p \)-SWAP across the two independent inputs \( \rho_{\Psi} \) and \( \rho_{\Sigma} \) conditioned via quantum measurements on the (separable) environmental subsystems \( \rho_{\Sigma E_1} \) and \( \rho_{\Sigma E_2} \) respectively. Finally, to find the conditional eigenvalues, we define the final states (conditional outputs) after local measurements on the subsystems \( E_1 \) and \( E_2 \) as

\[
\sigma^{(j)}_{E_1} = \frac{1}{q^{(j)}_E} E_1(\psi_j|\rho_{\Sigma E_1} \psi_j)_E \quad \text{and} \quad \sigma^{(k)}_{E_2} = \frac{1}{q^{(k)}_E} E_2(\phi_k|\rho_{\Sigma E_2} \phi_k)_E \quad \text{where} \quad q^{(j)}_E = E_1(\psi_j|\rho_{\Sigma E_1} |\psi_j)_E\quad \text{and} \quad q^{(k)}_E = E_2(\phi_k|\rho_{\Sigma E_2} |\phi_k)_E.
\]
\[
\sigma^{(j,k)}_Y := \frac{1}{p^{(12)}_{j,k}} E_{E_1} (\psi_j, \phi_k | \rho_{YE_1E_2} | \psi_j, \phi_k)_{E_1E_2}
\]
\[
= (N_\tau \otimes I_{E_1E_2}) \left( \frac{1}{q_j^{(1)}} E_{E_1} (\psi_j | \rho_{X_1E_1} | \psi_j)_{E_1} \otimes \frac{1}{q_k^{(2)}} E_{E_2} (\phi_k | \rho_{X_2E_2} | \phi_k)_{E_2} \right)
\]
\[
= N_\tau \left( \sigma^{(j)}_{X_1} \otimes \sigma^{(k)}_{X_2} \right)
\]
\[= \sigma^{(j)}_{X_1} \boxplus \tau \sigma^{(k)}_{X_2}.\]

Note that \( p^{(12)}_{j,k} := E_{E_1} (\psi_j, \phi_k | \rho_{YE_1E_2} | \psi_j, \phi_k)_{E_1E_2} = E_{E_1} (\psi_j | \rho_{X_1E_1} | \psi_j)_{E_1} \cdot E_{E_2} (\phi_k | \rho_{X_2E_2} | \phi_k)_{E_2} = q_j^{(1)} \cdot q_k^{(2)}, \)

since \( \rho_{YE_1E_2} = \rho_{E_1} \otimes \rho_{E_2} \) is separable.

By using theorem 1.1 in [35], we can naturally obtain that
\[
\lambda (\sigma^{(j)}_{X_1} \boxplus \tau \sigma^{(k)}_{X_2}) < \tau \lambda (\sigma^{(j)}_{X_1}) + (1 - \tau) \lambda (\sigma^{(k)}_{X_2}).
\]

This relation directly implies that specific local measurements after the p-SWAP operation do not affect the majorization relation for the conditional output states. Without loss of generality, we can generalize the (local) projective measurement to a (local) general measurement. For the main proof, we need the following definition, which is a natural extension of equation (5) (see also figure 1).

**Definition 1 (Output state of p-SWAP operation).** For any quantum states in the form \( \rho_{X_1X_2E_1E_2} := \rho_{X_1E_1} \otimes \rho_{X_2E_2} \), the output state through the partial swap operation with \( \tau \in [0, 1] \) on subsystems \( X_1 \) and \( X_2 \) is given by
\[
\rho_{YE_1E_2} = \tau \rho_{X_1E_1} + (1 - \tau) \rho_{X_2E_2} - \tau \sqrt{\tau(1 - \tau)} [\rho_{X_1E_1}, \rho_{X_2E_2}].
\]

By using definition 1 and equation (11), we can derive the following crucial lemma, namely the `conditional majorization relation` for our product d-level quantum states. First, we define \( \rho_{X_i | E_i(j)} := \frac{1}{q_j^{(1)}} \text{Tr}_{E_i} (M_{j(i)}^{(1)} \rho_{X_iE_i} M_{j(i)}^{(1)}) \) and \( \rho_{X_i | E_i(k)} := \frac{1}{q_k^{(2)}} \text{Tr}_{E_i} (M_{k(j)}^{(2)} \rho_{X_iE_i} M_{k(j)}^{(2)}) \), i.e. the outcome states after local measurements given by \( \{ M_{j(i)}^{(1)} \}_{E_i} \) and \( \{ M_{k(j)}^{(2)} \}_{E_i} \), where \( q_j^{(1)} = \text{Tr} (M_{j(i)}^{(1)} M_{j(i)}^{(1)} \rho_{E_i}) \) and \( q_k^{(2)} = \text{Tr} (M_{k(j)}^{(2)} M_{k(j)}^{(2)} \rho_{E_i}) \) on the environmental subsystems \( \rho_{E_i} \) and \( \rho_{E_i} \) respectively. Note that, for any \( j \), the measurement elements satisfy \( \sum_{j=1}^d M_j | M_j = I \).

**Lemma 1 (Conditional majorization relation).** For any pair of density matrices \( \rho_{X_1E_1}, \rho_{X_2E_2} \in D(\mathbb{C}^{d \times d_{E_1}}) \), any \( \tau \in [0, 1] \) and for all \( j, k \), if we take local measurements as \( \{ M_{j(i)}^{(1)} \}_{E_i} \) and \( \{ M_{k(j)}^{(2)} \} \) on the subsystems \( \rho_{E_i} \) and \( \rho_{E_i} \) respectively, then we have
\[
\rho_{Y | E_i(j)E_i(k)} = \rho_{X_i | E_i(j)} \boxplus \tau \rho_{X_i | E_i(k)}. \tag{14}
\]

This fact directly implies that, for each measurement outcome \( j \) and \( k \),
\[
\lambda (\rho_{Y | E_i(j)E_i(k)}) \prec \tau \lambda (\rho_{X_i | E_i(j)}) + (1 - \tau) \lambda (\rho_{X_i | E_i(k)}). \tag{15}
\]

Here, the environmental subsystem is given by \( \rho_{E_iE_i} = \rho_{E_i} \otimes \rho_{E_i} \) i.e. the separable state.

**Proof.** It is sufficient to prove that, for each \( j \) and \( k \), \( \rho_{Y | E_i(j)E_i(k)} = \rho_{X_i | E_i(j)} \boxplus \tau \rho_{X_i | E_i(k)} \).
That is,
\begin{equation}
\begin{aligned}
\rho_{Y}|_{E_{i}(j)E_{i}(k)} & := \frac{1}{P(j,k)} \text{Tr}_{E_{i}E_{i}} \left( (M^{(1)}_{j} \otimes M^{(2)}_{k}) \rho_{Y_{1},E_{i}} (M^{(1)}_{j} \otimes M^{(2)}_{k}) \right) \\
& = \left\langle \mathcal{N}_{\tau} \otimes \mathbb{1}_{E_{i}E_{i}} \right\rangle \left( \frac{1}{q_{j}^{(1)}} \text{Tr}_{E_{i}} (M^{(1)}_{j} \rho_{X_{j},E_{i}} M^{(1)}_{j}) \otimes \frac{1}{q_{k}^{(2)}} \text{Tr}_{E_{i}} (M^{(2)}_{k} \rho_{X_{k},E_{i}} M^{(2)}_{k}) \right) \\
& = \mathcal{N}_{\tau} (\rho_{X_{j}|_{E_{i}(j)} \otimes \rho_{X_{k}|_{E_{i}(k)}}) \\
& = \rho_{X_{i}|_{E_{i}(j)} \otimes \rho_{X_{j}|_{E_{i}(k)}},
\end{aligned}
\end{equation}

where we again use the fact that the probability \( p_{j,k}^{(1,2)} := \text{Tr}_{E_{i}E_{i}} \left( (M^{(1)}_{j} \otimes M^{(2)}_{k}) \rho_{Y_{1},E_{i}} (M^{(1)}_{j} \otimes M^{(2)}_{k}) \right) = \text{Tr}(M^{(1)}_{j} M^{(1)}_{j} \rho_{E_{i}}) \cdot \text{Tr}(M^{(2)}_{k} M^{(2)}_{k} \rho_{E_{i}}) = q_{j}^{(1)} \cdot q_{k}^{(2)} \) for the (separable) environmental system \( \rho_{E_{i}} = \rho_{E_{i} \otimes \rho_{E_{i}}} \). Second parts (i.e. equation (15)) are directly given by theorem 11 in [24] or theorem 1.1 in [35]. This completes the proof. \( \blacksquare \)

In the proof of lemma 1, for any Schur concave function \( f \), we can define its function values as

\begin{equation}
\begin{aligned}
f(\rho_{Y}|_{E_{i}E_{i}}) & = \min_{\{M^{(1)},M^{(2)}\}} \sum_{j,k} q_{j}^{(1)} q_{k}^{(2)} f(\rho_{Y}|_{E_{i}(j)E_{i}(k)}), \\
f(\rho_{X_{i}|_{E_{i}}}) & = \min_{\{M^{(1)}\}} \sum_{j} q_{j}^{(1)} f(\rho_{X_{j}|_{E_{i}(j)}}), \quad \text{and} \\
f(\rho_{X_{i}|_{E_{i}}}) & = \min_{\{M^{(2)}\}} \sum_{k} q_{k}^{(2)} f(\rho_{X_{k}|_{E_{i}(k)}}).
\end{aligned}
\end{equation}

Then by exploiting lemma 1, we can prove the following theorem, which is our main result.

**Theorem 1 (Conditional qudit EPI (CQ-EPI)).** Let \( \rho_{X_{i},E_{i}} \) and \( \rho_{X_{i},E_{i}} \) be any discrete \( d \times d \)-level quantum states with a separable environment \( \rho_{E_{i}} \otimes \rho_{E_{i}} \), \( \ell \in \{1,2\} \). For any concave and symmetric function \( \nu_{\kappa} \) with a range of \( 0 \leq \kappa \leq \frac{1}{(\log d)^{2}} \), and for any \( \tau \in [0,1] \), we have

\begin{equation}
\nu_{\kappa}(\rho_{Y}|_{E_{i}E_{i}}) \geq \tau \nu_{\kappa}(\rho_{X_{i}|_{E_{i}}}) + (1 - \tau) \nu_{\kappa}(\rho_{Y_{1}|_{E_{i}}}).
\end{equation}

**Proof.** For each measurement outcome \( j \) and \( k \), let \( \rho_{X_{j}|_{E_{i}(j)}}, \rho_{X_{k}|_{E_{i}(k)}} \in \mathcal{D}(\mathbb{C}^{d}) \) be diagonal states whose entries are the eigenvalues of \( \rho_{X_{j}|_{E_{i}(j)}} \) and \( \rho_{X_{k}|_{E_{i}(k)}} \) respectively, arranged in decreasing order. Since \( \lambda(\rho_{X_{i}|_{E_{i}(j)}}) = \lambda(\rho_{X_{j}|_{E_{i}(j)}}) \) and \( \lambda(\rho_{X_{k}|_{E_{i}(k)}}) = \lambda(\rho_{X_{k}|_{E_{i}(k)}}) \), we then have, from equation (15),

\begin{equation}
\begin{aligned}
\lambda(\rho_{Y}|_{E_{i}(j)E_{i}(k)}) & \leq \tau \lambda(\rho_{X_{i}|_{E_{i}(j)}}) + (1 - \tau) \lambda(\rho_{X_{i}|_{E_{i}(k)}}) \\
& = \lambda(\tau \rho_{X_{i}|_{E_{i}(j)}} + (1 - \tau) \rho_{X_{i}|_{E_{i}(k)}}).
\end{aligned}
\end{equation}

For any entropic function \( \nu_{\kappa}(\cdot) \) that is symmetric and concave in terms of eigenvalues of density matrices, we have

\begin{equation}
\begin{aligned}
\nu_{\kappa}(\rho_{X_{i}|_{E_{i}(j)}}) & \geq \nu_{\kappa}(\tau \rho_{X_{i}|_{E_{i}(j)}} + (1 - \tau) \rho_{X_{i}|_{E_{i}(k)}) \\
& \geq \tau \nu_{\kappa}(\rho_{X_{i}|_{E_{i}(j)}}) + (1 - \tau) \nu_{\kappa}(\rho_{X_{i}|_{E_{i}(k)}}) \\
& = \tau \nu_{\kappa}(\rho_{X_{i}|_{E_{i}(j)}}) + (1 - \tau) \nu_{\kappa}(\rho_{X_{i}|_{E_{i}(k)}}),
\end{aligned}
\end{equation}

J. Phys. A: Math. Theor. 51 (2018) 145303

K Jeong et al
where the first inequality follows from the Schur concavity, the second inequality follows from the concavity of the entropic function, and the last equality follows from the symmetry.

It follows that
\[
\sum_{j} q_{j}^{(1)} q_{k}^{(2)} \nu_{\kappa}(\rho_{Y|E_{1}(j)} E_{1}(k)) \geq \tau \sum_{j} q_{j}^{(1)} \nu_{\kappa}(\rho_{X_{1}|E_{1}(j)}) + (1 - \tau) \sum_{k} q_{k}^{(2)} \nu_{\kappa}(\rho_{X_{2}|E_{2}(k)})
\]
\[
\geq \tau \nu_{\kappa}(\rho_{X_{1}|E_{1}}) + (1 - \tau) \nu_{\kappa}(\rho_{X_{2}|E_{2}}).
\]

This completes the proof.

4. Discussion

In summary, we have investigated a conditional entropy power inequality for \(d\)-dimensional quantum systems under the assumption that ancillary environmental subsystems are separable. In the proof, we considered a post-measurement property of quantum states through a local quantum operation (especially measurement) after \(p\)-SWAP on \(d\)-level quantum states (i.e. qudits), and applied the well-known majorization technique to the (nonincreasing order of) eigenvalues of quantum states. Our construction \(C_{\kappa}\) might be useful in characterizing entanglement-assisted capacity such as for a thermal (white) noise Gaussian channel, or in quantum superdense coding.

We here discuss what is known about the entropy power inequality so far; a summary is provided in table 1. Let us denote the entropy photon number inequality by \(\text{EPNI}\) and the continuous variable (CV) regime by \(\lambda\). The CV \(\text{EPNI}\) proposed by Guha \(\text{et al}\) with an average photon number is an important open question in quantum Shannon theory, although recently some progress has been reported on this topic \cite{37–39}, but it is still unsolved in its original form. Furthermore, whether or not \(\kappa = \frac{1}{2}\) on \(\text{EPNI}\) \(\lambda\) is also an important conjecture. For the \(\kappa\) and \(C_{\kappa}\) on qudit versions, the entropy power inequality is still unknown for the value \(\kappa = \frac{1}{2}\) or \(\kappa > \kappa_{1}\). Also for the qudit \(\text{EPNI}\) with \(\kappa = \frac{1}{2}\) or \(\kappa > \kappa_{2}\), the entropy power inequality is open—we do not have any strong evidence for its concave property.

| Table 1. Summary of EPIs. |
|--------------------------|
| \(\nu_{\kappa}(\cdot)\) | Mixing operation | Constant \(\kappa\) |
| \(c_{\kappa}\) \(a\) | \(13–19\) \(b\) | \(\cdot\) | \(2/d\) |
| \(q_{\kappa}\) \(a\) | \(20, 21\) \(b\) | \(\tau\)-BS | \(1/D\) |
| \(q_{\kappa}\) \(a\) | \(24\) \(b\) | \(p\)-SWAP | \(\kappa \in [0, \kappa_{1}]\) |
| \(C_{\kappa}\) \(a\) | \(25, 26\) \(b\) | \(\tau\)-BS | \(1/D\) |
| \(C_{\kappa}\) \(a\) | \[Our proof\] \(b\) | \(p\)-SWAP | \(\kappa \in [0, \kappa_{1}]\) |
| \(\text{EPNI}\) \(a\) | \(22\) \(b\) | \(\tau\)-BS | \(1/D\) \[C\] |
| \(\text{EPNI}\) \(a\) | \(24\) \(b\) | \(p\)-SWAP | \(\kappa \in [0, \kappa_{2}]\) |

\(a\) Continuous variable (CV);
\(b\) Hold (or proved);
\(c\) Convolution;
\(\tau \in [0, 1]\): a mixing parameter;
BS: beamsplitter;
\(D\): \(D\)-mode;
\(d\): dimensionality;
\(\kappa_{1} := \frac{1}{\ln d}\);
\(\kappa_{2} := \frac{1}{d - 1}\);
\(d\) unknown; [C]: conjectured.
Finally, we have open questions of several different kinds. For example, some dual relations on EPI and qEPI (and also conditional versions of EPI) in the sense of a complementary quantum channel might be intriguing; moreover, certain inequalities of EPIs for different (or hybrid) inputs also seem to be important. It would also be interesting to study whether or not a (conditional) quantum entropy power inequality holds for quantum conditional states [36], as well as for general multipartite quantum systems.
