Quantum geometrodynamics with intrinsic time development and momentric variables is presented. An underlying SU(3) group structure at each spatial point regulates the theory. The intrinsic time behavior of the theory is analyzed, together with its ground state and primordial quantum fluctuations. Cotton–York potential dominates at early times when the universe was small; the ground state naturally resolves Penrose’s Weyl curvature hypothesis, and thermodynamic and gravitational “arrows of time” point in the same direction. Ricci scalar potential corresponding to Einstein’s general relativity emerges as a zero-point energy contribution. A new set of fundamental commutation relations without Planck’s constant emerges from the unification of gravitation and quantum mechanics.

Subject Index E00, E03, E05

1. Intrinsic time development, and momentric variables as SU(3) generators

A century after the birth of Einstein’s general relativity (GR), successful quantization of the gravitational field remains the preeminent challenge. Geometrodynamics with a positive definite spatial metric is the simplest consistent framework to implement fundamental canonical commutation relations (CR) predicated on the existence of spacelike hypersurfaces. In quantum gravity, spacetime is a "concept of limited validity" [1] and “time” must be determined intrinsically” [2]. A full theory of quantum geometrodynamics dictated by first-order Schrödinger evolution in intrinsic time, $(i\hbar)^{1/2}\delta/\psi_1 = \mathcal{H}_{\text{Phys}}$, and equipped with a diffeomorphism-invariant physical Hamiltonian and time-ordering was formulated recently [3,4]. Decomposition of the fundamental geometrodynamical degrees of freedom $(q_{ij}, \tilde{\pi}^{ij})$ singles out the canonical pair $(\ln q^{1/3}, \tilde{\pi})$, which commutes with the remaining unimodular $\tilde{q}_{ij} = q^{-1/3}q_{ij}$ and traceless $\tilde{\pi}^{ij} = q^{1/3}(\tilde{\pi}^{ij} - 1/3 q^{ij}\tilde{\pi})$. Hodge decomposition for compact manifolds yields $\delta \ln q^{1/3} = \delta T + \nabla_i \delta Y^i$, wherein the spatially independent $\delta T$ is a three-dimensional diffeomorphism-invariant (3dDI) quantity which serves as the intrinsic time interval, whereas $\nabla_i \delta Y^i$ can be gauged away since $\mathcal{L}_{\Delta N} \ln q^{1/3} = 3/3 \nabla_i \delta N^i$. The Hamiltonian, $\mathcal{H}_{\text{Phys}} = \int \frac{\mathcal{H}(x)}{p} \ d^3 x$, and ordering of the time development operator $U(T, T_0) = T \{ \exp \left[ -\frac{i}{\hbar} \int_{T_0}^{T} \mathcal{H}_{\text{Phys}}(T') \delta T' \right] \}$ are 3dDI provided

$$\tilde{H} = \sqrt{\tilde{\pi}^{ij} \tilde{G}_{ijkl} \tilde{\pi}^{kl}} + \mathcal{V}[q_{ij}]$$

is a scalar density of weight one [3]. Einstein’s GR (with $\beta = \frac{1}{\sqrt{6}}$ and $\mathcal{V} = -\frac{q}{(2\pi)^2}(R - 2\Lambda_{eff})$) is a particular realization of this wider class of theories.$^1$

Difficulties in implementing $\pi^{ij}$ as a self-adjoint traceless operator in the metric representation lead us to summon the momentic variable, which is classically $\bar{q}_{ij} = q_{jm}q^{im}$. The fundamental CR is restriction of Klauder’s affine algebra (see [5] and references therein) to the traceless momentic and unimodular part of the spatial metric,

$$\left[ \bar{q}_{ij}(x), \pi_{kl}(y) \right] = 0, \quad \left[ \bar{q}_{ij}(x), \pi^k_l(x) \right] = i\hbar \bar{E}^k_{(ij)} \delta(x - y),$$

$$\left[ \pi^i_j(x), \pi^k_l(y) \right] = \frac{i\hbar}{2} \left( \delta^k_j \pi^i_l - \delta^i_j \pi^k_l \right) \delta(x - y);$$

wherein $\bar{E}^i_{(mn)} = \frac{1}{2}(\delta^i_m q_{jn} + \delta^i_n q_{jm}) - \frac{1}{2}\delta^i_j q_{mn}$ (with properties $\delta^i_j \bar{E}^i_{(mn)} = \bar{E}^i_{(mn)} q^mn = 0$; $\bar{E}_{jil} = \bar{E}_{jli} = \frac{2}{3}\bar{q}_{jl}$) is the vielbein for the supermetric $\tilde{G}_{ijkl} = \bar{E}^m_{n(ij)} \bar{E}^n_{m(kl)}$. Quantum mechanically, the momentic operators and CR can be explicitly realized in the metric representation by

$$\hat{\pi}^i_j(x) = \frac{\hbar}{i} \bar{E}^i_{(mn)}(x) \frac{\delta}{\delta q_{mn}(x)} = \frac{\hbar}{i} \frac{\delta}{\delta q_{mn}(x)} \bar{E}^i_{(mn)}(x) = \hat{\pi}^{*i}_j(x),$$

which are self-adjoint on account of $\left[ \frac{\delta}{\delta q_{mn}(x)}, \bar{E}^i_{(mn)}(x) \right] = 0$. These eight momentic variables generate $SL(3,R)$ transformations of $\bar{q}_{ij}$ that preserve positivity and unimodularity. Moreover, it is crucial to realize that they generate, by themselves, at each spatial point, an $SU(3)$ algebra. In fact, with Gell-Mann matrices $\lambda^A = 1, \ldots, 8$, $T^A(x) = \frac{1}{\hbar a(0)}(\lambda^A)_i^j \hat{\pi}^i_j(x)$ satisfy $[T^A(x), T^B(y)] = if^{ABC} T^C \frac{\delta(x-y)}{\delta a(0)}$ with $SU(3)$ structure constants $f^{ABC}$.

Perturbative renormalizability of GR can be attained by adding higher-derivative terms, but 4-covariance locks higher temporal and spatial derivatives to the same order, compromising the stability and unitarity of the theory [7]. The paradigm shift from 4-covariance to 3dDI not only resolves the “problem of time,” but also leads to the generic weight two (semi-)positive definite potential [3],

$$\mathcal{V} = \left[ \frac{1}{2}(\bar{q}_{ik}\bar{q}_{jl} + \bar{q}_{il}\bar{q}_{jk}) + \gamma \bar{q}_{ij}\bar{q}_{kl} \right] \bar{W}^{ij} \bar{W}^{kl}, \quad \gamma \geq -\frac{1}{3};$$

$$\bar{W}^i_j = \left[ \sqrt{q} \ (\Lambda' + a'R) \delta^i_j + bh\sqrt{q} \tilde{R}^i_j + gh\tilde{C}^i_j \right];$$

wherein $R$ and $\tilde{R}^i_j$ are respectively the scalar and traceless parts of the spatial Ricci curvature, while $\tilde{C}^i_j$ is the Cotton–York tensor (density) which is third order in spatial derivatives and associated with the dimensionless coupling constant $g$. In conjunction with intrinsic time evolution with $H_{\text{Phys}}$, this framework presents, in quantum gravity, a new vista to surmount conceptual and technical obstacles.

$^1$ On account of the quadratic dependence on momenta and ordering ambiguities of the Hamiltonian, which also depends on the intrinsic time, this formulation can reproduce the physics of the usual Wheeler–DeWitt (WDW) equation only at the classical limit, and certainly not at the quantum level. There are valid reasons not to replicate the second-order Klein–Gordon-like WDW scheme which, among other difficulties, fails to yield a positive definite conserved probability density if we adhere to the “one-universe picture” and do not invoke third quantization. Rather, this quantum mechanically inequivalent formulation overcomes, in conjunction with intrinsic time evolution, many of the conceptual and technical problems of the WDW scheme, but ensures that the classical low-curvature limit of Einstein’s GR is recovered.
2. Free Hamiltonian

The free theory is characterized by $SU(3)$ invariance generated by the momenetric (whereas $\pi^{ij}$ generate translations which do not preserve the positivity of the metric), because the Casimir invariant $T^A T^A$ is related to the kinetic operator in Eq. (1) through

$$\frac{\hbar^2 \delta^2 (0)}{2} T^A T^A = \hat{\pi}^{i \dot{j}} \hat{\pi}^{\dot{j}} = \hat{\pi}^{i \dot{j}} \hat{\pi}^{\dot{j}} = \hat{\pi}^{i \dot{j}} \hat{G}_{ij kl} \hat{\pi}^{kl}.$$

(5)

The upshot is its spectrum can be labeled by eigenvalues of the complete commuting set at each spatial point comprising the two Casimirs $L^2 = T^A T^A$, $C = d_{ABC} T^A T^B T^C \propto \det (\hat{\pi}^{i \dot{j}})$; Cartan subalgebra $T^3, T^8$, and isospin $I = \sum_{B=1}^3 T^B T^B$. An underlying group structure has the advantage that the action of the momenetric on wavefunctions by functional differentiation can be traded for its well-defined action as generators of $SU (3)$ on states expanded in this basis, since

$$\frac{\hbar}{i} \left( \lambda^A \right)_{j}^{\dot{j}} \delta_{i (mn)}^{\delta} (x) \left( \bar{q}_{kl} \left| \prod_{i} l^{2}, C, I, m_{3}, m_{8} \rightangle_{y} \right) = \frac{\hbar \delta (0)}{2} \left( \bar{q}_{kl} \right| T^{A} (x) \prod_{i} l^{2}, C, I, m_{3}, m_{8} \right)_{y}.$$

(6)

For the free theory, the ground state with zero energy, $|0\rangle$, corresponds to $l^2 = 0 \forall x$, which is an $SU (3)$ singlet state annihilated by all the momenetric operators $(\hat{\pi}^{i \dot{j}} (x) |0\rangle = 0)$; it is also 3dDI because $-2 \nabla_j \hat{\pi}_i^{\dot{j}}$ generates spatial diffeomorphisms of $\bar{q}_{ij}$.

3. Asymptotic behavior of the Hamiltonian at early and late intrinsic times

Hodge decomposition for $\delta \ln q^{-1}$ and its Heisenberg equation of motion leads to $\frac{\delta}{\delta T} \ln q^{1/2} (x, T) = \frac{2}{\pi T} \ln q^{1/2} + \frac{1}{2 T} \left[ \ln q^{1/2}, H_{phys} \right]$ = 1, with solution $\ln \left[ \frac{q (x, T)}{q (x, T_{now})} \right] = 3 (T - T_{now})$, and $-\infty < T < \infty$. Moreover, the Hodge decomposition also implies that the change in the global intrinsic time is proportional to the logarithmic change in the volume of the universe, $\delta T = \frac{2}{3} \delta \ln V$, i.e. $T - T_{now} = \frac{2}{3} \ln (V / V_{now})$. Explicitly separating out $T$-dependence from entities (labeled with overline) which depend only on $\bar{q}_{ij}$,

$$\bar{W}_{i}^{j} = \left[ \sqrt{q} \left( \Lambda' + a^2 R \right) \delta_{i}^{j} + b' \sqrt{q} \bar{R}_{i}^{j} + g h \bar{C}_{i}^{j} \right]$$

$$= \left[ \sqrt{q} \left( \Lambda' + a^2 q^{-3/2} \bar{q}^{kl} \bar{R}_{kl} \right) \delta_{i}^{j} + b' \sqrt{q} q^{-1/2} \bar{q}_{ik} \bar{R}_{kj} + g h \bar{C}_{i}^{j} \right] + (\partial_i \ln q \text{ terms}),$$

(7)

with the $q^{-1}$-independent Cotton–York tensor density $\bar{C}_{i}^{j}$ which is conformally invariant. The theory is not (intrinsic) time-reversal invariant; furthermore, the exponential scaling behavior of $q$ with intrinsic time implies that in the limit $T - T_{now} \rightarrow -\infty$, $V / V_{now} \rightarrow 0$ (i.e. early times, when the universe was very small in volume), the potential $\bar{V}$ was dominated by the Cotton–York term, whereas the limit $T - T_{now} \rightarrow \infty$, $V / V_{now} \rightarrow \infty$ (i.e. late times, when the universe becomes large) will be dominated by the cosmological constant term. This is compatible with current observations of our ever expanding universe, with a middle period in which curvature and cosmological terms are comparable in importance.

\(^{2}\)In FLRW cosmology, the intrinsic time interval can be measured through the redshift $z$. 

3/8
4. Early universe and Cotton–York dominance

In the era of Cotton–York dominance at the beginning of the universe, \( \tilde{H} = \sqrt{\hat{\pi}^2 + g^2 \hbar^2 \hat{C}_j} \). A number of intriguing facts conspire to simplify and regulate the Hamiltonian: The traceless Cotton–York tensor density is expressible as \( \hat{C}_j = \hat{E}_{j(mn)} \delta W \), wherein \( W = \frac{1}{2} \int e^{ijk} \left( \hat{\Gamma}_j^{im} \hat{\partial}_j^{m} \hat{\Gamma}_k^{n} + \frac{2}{3} \hat{\Gamma}_i^{im} \hat{\Gamma}_j^{mn} \right) d^3x \) is the 3d DI Chern–Simons functional of the affine connection of \( \hat{\partial}_{ij} \). This leads to the similarity transformation of the momentric,

\[
\hat{Q}_j = e^{gW} \hat{\pi}_j e^{-gW} = \frac{\hbar}{i} \hat{E}_{j(mn)} \left[ \frac{\delta}{\delta q_{mn}} - g \frac{\delta W}{\delta q_{mn}} \right] = \frac{\hbar}{i} \hat{E}_{j(mn)} \frac{\delta}{\delta q_{mn}} + i g \hbar \hat{C}_j. \tag{8}
\]

Moreover, \( [\hat{\pi}_j, \hat{C}_j] = 0 \), i.e. without the zero-point energy (ZPE) contribution.\(^3\) Consequently, the Hamiltonian density is simply \( \hat{H} = \sqrt{\hat{\pi}^2 + g^2 \hbar^2 \hat{C}_j} \). While \( \hat{Q}_j \) and \( \hat{Q}_j^\dagger \) are related to \( \hat{\pi}_j \) by \( e^{\pm gW} \) similarity transformations, they are non-Hermitian and generate two unitarily inequivalent representations of the non-compact group \( SL(3, R) \) at each spatial point; whereas the momentric \( \hat{\pi}_j = \frac{1}{2} (\hat{Q}_j + \hat{Q}_j^\dagger) \) generates a unitary representation of \( \prod \_x SU(3)_x \).

5. Initial state of the universe and Penrose’s Weyl curvature hypothesis

From the classical perspective, \( \tilde{H} = \sqrt{\hat{\pi}^2 + g^2 \hbar^2 \hat{C}_j} \) attains its lowest value iff the momentric and Cotton–York tensor vanish identically, the latter being precisely the criterion for conformal flatness in three dimensions.\(^4\) The vanishing of the momentric (hence the traceless part of the classical extrinsic curvature) and spatial conformal flatness at \( T \to -\infty (q \to 0) \) realize a Robertson–Walker Big Bang compatible with Penrose’s hypothesis that the initial singularity must have a vanishing four-dimensional Weyl curvature tensor. A solar-mass black hole has a Bekenstein–Hawking entropy of \( \sim 10^{82} \) per baryon. By Penrose’s estimate, with \( 10^{80} \) baryons in our universe, thermalization of gravitational degrees of freedom at the initial hot Big Bang would imply an entropy of \( 10^{123} \). “Our extraordinarily special Big Bang” with low entropy [8–11] emerges naturally from the ground state of \( H_{\text{Phys}} \) in the era of Cotton–York dominance; and the Second Law thermodynamic “arrow of time” and “gravitational arrow of intrinsic time” (of increasing volume) point in the same direction.

The vanishing of both the traceless momentric and the Cotton–York tensor implies that the trace of the momentum \( \pi \propto \tilde{H} \) also vanishes; the extrinsic curvature is thus totally absent, which is the junction condition needed for Euclidean continuation of the metric (for instance, continuation to Euclidean \( S^4 \) at the conformally flat \( S^3 \) section at the throat of the Lorentzian de Sitter metric). The quantum context may be in agreement with the Hartle–Hawking “no-boundary proposal” for the wavefunction of the universe [12], but it should be noted that the intrinsic time framework discussed

\(^3\) The commutator is a scalar density of weight two, with the density weight carried by \( \lim_{x \to y} \delta(x - y) \) and the Levi–Civita tensor density from \( \hat{C}^{ij} \propto e^{(i m n) \mathfrak{R}^k} \). Contraction over spatial indices of \( e^{i m n} \) with \( q_{m n} \) and \( R_{m n} \), and \( e^{ij} V_i V_j V_k \) all vanish, the latter due to the Bianchi identity. Explicit computations verify the vanishing of the commutator.

\(^4\) Cotton–York dominance at very early times is robust against the inclusion in \( \mathcal{Y} \) of the usual Yang–Mills fields or fermionic matter, because the corresponding Hamiltonian densities contain positive powers of \( q \) as \( (T \to \infty) \sim e^{2(T - T_{\text{min}})} \). Conventional scalar field potentials also contain positive powers of \( q \), but the weight two kinetic term \( \pi^2 \) is independent of \( q \). However, this does not change the criterion of vanishing momentric and Cotton–York tensor for the classical lowest energy state, which then requires \( \pi^2 = 0 \) as well.
here already allows a continuation of $\beta$ in $H_{\text{Phys}}$ to imaginary values and Euclidean partition functions; moreover, from the formula of the emergent lapse function [3], imaginary $\beta$ leads to emergent semi-classical spacetimes which are Euclidean in signature.

The Cotton–York interaction is introduced through the extension $\hat{\pi}_j^i \rightarrow e^{gW} \hat{\pi}_j^i e^{-gW} = \hat{\tilde{\pi}}_j^i$; thus $\hat{\tilde{Q}}_j^i$ and $\hat{\tilde{\pi}}_j^i$ respectively annihilate the state $e^{\pm gW} [0]$. Moreover, both these states are annihilated by $\hat{H}$ because $\hat{\tilde{Q}}_j^i \hat{\tilde{Q}}_i^j = \hat{\tilde{Q}}_j^i \hat{\tilde{Q}}_i^j$, due to the absence of Cotton–York ZPE. So any linear combination $A e^{gW} [0] + B e^{-gW} [0] = N \cosh[g (W - W_o)] [0]$ is a zero energy state. From the quantum perspective, the classical conformally flat configuration with vanishing Cotton–York tensor is the extremum of $W$, and thus precisely a saddle point for the ground state wavefunction $\Psi_0[\hat{q}_{ij}] = N \cosh[g (W - W_o)] [\hat{q}_{ij}] [0]$ (with the simplest choice of constant $[\hat{q}_{ij}] [0]$). Expanding $W$ about the saddle point $\delta W \bar{\delta q}_{ij} = \bar{\tilde{Q}}_j^i = 0$ leads to

$$W[\hat{q}_{ij}] - W_o = W \left[ \Gamma \left( \tilde{C}_j^i = 0 \right) \right] + \frac{1}{2} \int d^3x \int d^3y \, \delta \hat{q}_{ij} (x) H^{ijkl}_{ij}(x, y) \bigg|_{\delta \hat{C}_{jk} = 0} \bar{\delta q}_{kl} (y)$$

(9)

wherein $H^{ijkl}_{ij}(x, y) = \frac{\delta^2 W}{\delta q_{ij}(x) \delta q_{kl}(y)}$ is the Hessian; it is natural to choose $W_o$ to cancel the zeroth-order term $W \left[ \Gamma \left( \tilde{C}_j^i = 0 \right) \right]$, which is the Chern–Simons functional of a conformally flat connection.5 $W_o = W \left[ \Gamma \left( \tilde{C}_j^i = 0 \right) \right]$ is a topological entity, invariant under infinitesimal variations of the metric. The ground state will thus contain primordial quantum fluctuations which can be studied. For instance, the Hessian, which for a flat metric is $-\frac{1}{2} \delta^2 \epsilon^{imln} g_{mn} \partial^2 \delta (x - y)$, is the inverse of the two-point correlation function, and Cotton–York dominance would thus be compatible with $\sim 1/k^3$ behavior. With $|N|^{-2} = \int [D\hat{q}] \cosh^2[g (W - W_o)]$, the wavefunction is normalized, but its definition involves the computation of $\int [D\hat{q}] e^{\pm 2gW(W - W_o)}$ which are just partition functions of Chern–Simons actions.6

5 The Chern–Simons functional is not bounded, because under a large $SL(3, R)$ transformation it shifts by a value proportional to the winding number of the transformation. Since $W$ appears in the wavefunction not as a phase factor, but as an exponential factor, quantization of the coupling constant cannot cure this problem. Instead, the natural choice is to cancel the contribution of the winding number with the Chern–Simons functional of a flat connection (see, for instance, Ref. [13]). Two configurations, $\Gamma$ and $\Gamma_o$, related by transformation $g_n$ with winding number $n$ will then produce the same value $W[\Gamma_o] - W \left[ \Gamma_o \left( \tilde{C}_j^i = 0 \right) \right] = W[\Gamma] - W \left[ \Gamma \left( \tilde{C}_j^i = 0 \right) \right]$, and the wave function will be periodic under $g_n$.

6 The partition function of the total $W_T$ can be defined, in the sense that the combined three-dimensional Einstein–Hilbert and Chern–Simons actions are renormalizable even though the dimension of $b$ is $\frac{1}{2}$. In fact, the Cotton–York Chern–Simons theory is the UV completion of the Einstein–Hilbert action. Perturbing about the flat metric (which is an extremum of the combined action) yields the Hessian for transverse traceless $\delta \hat{q}_{ij}$ modes as $(b^{\delta k^l} \delta^j_l - g^{\delta^k_l} \epsilon^{imln} g_{mn}) \partial^2 \delta (x - y)$. At large momenta, Chern–Simons theory dominates the propagator with $1/k^3$ behavior, which signifies renormalizability, as loop integrals are over $d^3k$ and the vertices are at most cubic in $k$; while at low momenta the Einstein–Hilbert $1/k^2$ behavior dominates. Saddle point steepest descent computation about the extremum of $W$ is a good approximation in the event of large $g$ (i.e. the limit of small $\epsilon$ coupling, $\frac{1}{\sqrt{\epsilon}}$, in the vertices in Chern–Simons perturbation theory), and the quadratic term of the Hessian will be the main contribution, so we expect $1/k^3$ two-point correlation functions in primordial quantum fluctuations, tempered by $1/k^2$ behavior of Einstein’s theory for small enough values of $k$ to make $\frac{b}{\sqrt{\epsilon}}$ significant.
6. Emergence of Einstein–Hilbert gravity

Ricci curvature terms become increasingly important in the potential after the initial era of Cotton–York dominance. They can be introduced in a manner which preserves the underlying structure which regulates the Hamiltonian by extending the Chern–Simons action with 3dDI invariants of the spatial metric. This not only guarantees 3dDI invariance, but also makes the Hamiltonian density the square root of a (semi-)positive definite and self-adjoint object \( \hat{\mathcal{J}}_i \hat{\mathcal{J}}^j \) and ensures the preservation of all these properties even under renormalization of the coupling constants. In increasing order of spatial derivatives, these invariants are \( \lambda \int \sqrt{g} d^3x \), \( EH = b \int \sqrt{q} R d^3x \), and the Chern–Simons functional of the affine connection with dimensionless coupling constant. Even higher-derivative curvature invariants will come along with super-renormalizable dimensional coupling constants, while the cosmological constant volume term commutes with \( \hat{\mathcal{J}}_i \) due to the traceless projector \( \hat{\mathcal{E}}_i^{(mm)} \). To wit, only the Einstein–Hilbert action in three dimensions and the Chern–Simons functional are relevant, i.e. total \( W_T = \frac{g}{4} \int e^{ijk} \left( \bar{\Gamma}^l_{im} \bar{\Gamma}^m_{jk} + \frac{2}{3} \bar{\Gamma}^l_{im} \bar{\Gamma}^m_{jn} \bar{\Gamma}^n_{kl} \right) d^3x + b \int \sqrt{q} R d^3x \). This leads to

\[
\hat{\mathcal{J}}_j = e^{W_T} \hat{\pi}_j e^{-W_T} = \frac{\hbar}{i} \hat{\mathcal{E}}_j^{(mm)} \left[ \frac{\delta}{\delta q_{mn}} - \frac{\delta W_T}{\delta \bar{q}_{mn}} \right] = \frac{\hbar}{i} \hat{\mathcal{E}}_j^{(mm)} \frac{\delta}{\delta \bar{q}_{mn}} + ib \hbar \sqrt{q} \bar{R}_j + i \hbar \bar{C}_j,
\]

wherein (again due to the \( \hat{\mathcal{E}}_j^{(mm)} \) projector) only the traceless part of the Ricci tensor remains. The Hamiltonian density is then

\[
\hat{H} = \sqrt{\hat{\mathcal{J}}_i \hat{\mathcal{J}}^i} = \sqrt{\hat{\pi}_i \hat{\pi}^i + \hbar^2 \left( g \hat{C}_i^j + b \sqrt{q} \bar{R}_j \right)} \left( g \hat{C}_i^j + b \sqrt{q} \bar{R}_j \right) + \left[ \hat{\pi}_i^j, ib \sqrt{q} \bar{R}_i^j \right],
\]

wherein the ZPE from incorporating the Einstein–Hilbert action in \( W_T \) is \( \left[ \hat{\pi}_i^j, ib \sqrt{q} \bar{h} \bar{R}_i^j \right] = -\frac{5}{12} b \hbar^2 \delta (0) \sqrt{q} (5R - \frac{\dot{q}}{q}) \).\(^7\) Remarkably, the potential for Einstein’s theory, which is the Ricci scalar, and a (positive) c-number term emerge. This means that the simple Hamiltonian density \( \sqrt{\hat{\mathcal{J}}_i \hat{\mathcal{J}}^i} \) (with all its aforementioned advantages) already contains Einstein’s GR with a cosmological constant. Furthermore, \( \bar{R}_i^j \) and the Cotton–York tensor only appear in the higher-curvature higher-derivative combination \( \left( g \hat{C}_i^j + a \sqrt{q} \bar{R}_j \right) \left( g \hat{C}_i^j + a \sqrt{q} \bar{R}_j \right) \)—these “non-GR” terms are automatically absent in homogeneous FLRW cosmology (that the Weyl curvature hypothesis holds in the Cotton–York era has been addressed), and also in constant curvature slicings of Painlevé–Gullstrand solutions of black holes [14]. Consequently, except for Cotton–York preponderance at very early times, Einstein’s GR dominates at low curvatures and long wavelengths in a theory in which “four-dimensional symmetry is not a fundamental property of the physical world” [15].

\(^7\) Explicit computations yield \( \left[ \hat{\pi}_i^j, ib \sqrt{q} \bar{h} \bar{R}_i^j \right] = -5 \hbar^2 \sqrt{q} \left( \frac{\delta}{\delta q} \bar{R} + \frac{1}{3} \bar{\nabla}^2 \delta (0) \right) \). The heat kernel, \( K (\epsilon; x, y) \) with \( \lim_{\epsilon \rightarrow 0} K (\epsilon; x, y) = \delta (x - y) \), presents, in the coincidence limit and with infinitesimal \( \epsilon \), the means to regularize \( \bar{\nabla}^2 \delta (0) \) for generic metrics. In terms of Seeley–DeWitt coefficients \( b_n, \sigma_n (x, y) \) the square of the geodesic length, \( \Delta_V \) the Van Vleck determinant, \( K (\epsilon; x, y) = (4\pi \epsilon)^{-3/2} \Delta_V^{1/2} \sqrt{q} (y) \epsilon^{-0(x, y)} e^{\alpha \sum_{n=0}^{\infty} b_n (x; y; \sqrt{\epsilon})} e^n \), wherein \( \epsilon \) is of dimension \( L^2 \). Thus the heat kernel equation implies \( \bar{\nabla}^2 K (\epsilon; x, y) = \frac{\partial K (\epsilon; x, y)}{\partial \epsilon} \rightarrow - \left( \frac{3}{2\epsilon} - b_1 \right) \delta (0) \) in the \( x = y \) and infinitesimal \( \epsilon \) limit. The Seeley–DeWitt coefficient \( b_1 = \frac{\pi}{6} \) yields \( \left[ \hat{\pi}_i^j, ib \sqrt{q} \bar{h} \bar{R}_i^j \right] = -\frac{5}{12} \hbar^2 \delta (0) \sqrt{q} (5R - \frac{\dot{q}}{q}) \).
7. Quantum geometrodynamics redux

Local $SL (3, R)$ transformations of $\tilde{q}_{kl}$ are generated through $U^\dagger (\alpha) \tilde{q}_{kl} (x) U (\alpha) = \left( e^{\frac{\alpha(x)}{\beta}} \right)_k^m \tilde{q}_{mn} (x) \left( e^{\frac{\alpha(x)}{\beta}} \right)_l^n$, wherein $U (\alpha) = e^{-\frac{\hbar}{2} \int \phi_j \pi^j d^3y} [5]$, while the generator of spatial diffeomorphisms for the momentic and unimodular spatial d.o.f. is effectively $D_i = -2\nabla_j \tilde{\pi}^j_i$, with smearing $\int N^i D_i d^3x = \int (2\nabla_j N^i) \tilde{\pi}^j_i d^3x$ after integration by parts. The action of spatial diffeomorphisms can thus be subsumed by specialization to $\alpha_j^i = 2\nabla_j N^i$, with the upshot that $SL (3, R)$ transformations which are not spatial diffeomorphisms are parametrized by $\alpha_j^i$ complement to $2\nabla_j N^i$. Given a background metric $q_{ij}^B = \frac{\sqrt{\rho}}{\rho} \tilde{q}_{ij}^B$, this complement is precisely characterized by the choice of transverse traceless (TT) parameter $(\alpha_{TT})_j^i := \frac{\sqrt{\rho}}{\rho} \frac{\alpha_{Phys}}{\beta} (\alpha_{TT})_j^i$, because the condition $\nabla_j^i \alpha_{Phys} (\alpha_{TT})_j^i = 0$ excludes non-trivial $N^i$ through $\nabla_j^i N^i = 0$ if $(\alpha_{TT})_j^i$ were of the form $2\nabla_j^i N^i \left( \text{the label} \ B \ \text{denotes the connection of} \ \tilde{q}_{ij}^B \right)$. TT conditions impose four restrictions on the symmetric $\alpha_{Phys} (x)$, leaving exactly two free parameters. The action of $U_{\text{Phys}} (\alpha_{TT}) = e^{-\frac{\hbar}{2} \int (\alpha_{TT})_j^i \tilde{\pi}^j_i d^3x}$ (which is thus local $SL (3, R)$ modulo spatial diffeomorphism) on any 3dDI wavefunction would result in an inequivalent state. The caveat is that TT conditions require a particular background metric to be defined. However, in Ref. [16] a basis of infinitely squeezed states was explicitly realized by Gaussian wavefunctionals $\Psi [q \eta^B] \propto \exp \left[ -\frac{1}{2} \int \tilde{f}_k \left( q_{ij} - q_{ij}^B \right) \tilde{\alpha}_{ij}^B \left( q_{ij} - q_{ij}^B \right) d^3x \right]$. 3dDI is recovered in the limit of zero Gaussian width with divergent $\lim_{\beta \to 0} \tilde{f}_k \to \delta (0)$. These localized Newton–Wigner states are infinitely peaked at $q_{ij}^B$, which can be deployed to actualize the TT conditions. The action of $U_{\text{Phys}} (\alpha_{TT})$ on these states would thus generate two infinitesimal local physical excitations at each spatial point.

In the preceding discussions, the entity $\delta (0)$ that denotes the three-dimensional coincidence limit, $\lim_{x \to y} \delta (x \to y)$, was left untouched, with the understanding that it can be regularized, for instance, by normalized Gaussians of infinitesimal but non-zero width. However, the underlying $SU (3)$ structure already provides unambiguous guidance on how to regularize the theory. The Hamiltonian assumes the elegant form

$$H_{\text{Phys}} = \hbar \int \sqrt{\left( Q^A \right)^\dagger Q^A} \frac{\delta (0)}{\sqrt{2\beta}} d^3x, \quad Q^A := e^{WT} T^A (x) e^{-WT}, \quad (12)$$

wherein $\frac{\delta (0)}{\sqrt{2\beta}} d^3x$ is a dimensionless volume element, its divergence to be absorbed by renormalization of $\beta$. With the cancelation of $\hbar$ on both sides of the Schrödinger equation, our universe is described by a fundamental equation with dimensionless Hamiltonian and intrinsic time. What is paramount to causality is not the actual dimension of time (an exemplar is the intrinsic time interval measured with dimensionless redshift in FLRW cosmology), but the sequence and ordering in time. Even as $\hbar$ will continue to leave its imprints in physics in the conversion factor between $SU (3)$ generators.

---

8 In the full diffeomorphism generator, $H_i = -2q_{ik} \nabla_j \tilde{\pi}^{kj} = D_i - \frac{2}{\beta} \nabla_i \tilde{\pi}$, the last term separately generates diffeomorphisms of \( \left( \ln q^\frac{1}{\beta} \right) \) and commutes with the momentric and spatial unimodular d.o.f.

9 It is conventional for the spatial label $x$ to carry the dimension of length, even though it is non-dynamical and a mere dummy variable to be integrated over. But it makes more physical sense to take partial derivatives, and calculate curvatures, with respect to a dimensionless variable $X = x/L$. To wit, $W_T = g W [\Gamma (X)] + (bL) \int \sqrt{q (X)} R (X) d^3X$, with dimensionless coupling constant $(bL)$; furthermore, $\frac{\delta \rho}{\beta} d^3x = \frac{1}{\beta} \lim_{y \to x} \delta (y - x) d^3x = \frac{1}{\beta} \lim_{y \to x} \delta (Y - X) d^3X$. 

7/8
\( T^A \) and the momentric (hence the momentum of the gravitational field), unification of gravitation and quantum mechanics comes with the demotion of its elementary significance. With dimensionless fundamental variables, the CR are:\(^{10}\)

\[
\left[ \tilde{q}_{ij} (x) , \tilde{q}_{kl} (y) \right] = 0 ,
\]
\[
\left[ \tilde{q}_{ij} (x) , T^A (y) \right] = i \frac{1}{2} \left( (\lambda^A)^k_i \tilde{q}_{kj} + (\lambda^A)^k_j \tilde{q}_{ki} \right) \frac{\delta (x - y)}{\delta (0)} ,
\]
\[
\left[ T^A (x) , T^B (y) \right] = i f^{ABC} c C^C \frac{\delta (x - y)}{\delta (0)} .
\]

Quantum essence is still embodied in the non-commutativity, but Planck’s constant is absent.
