In vitro antiplasmodial and cytotoxic properties of some medicinal plants from western Burkina Faso

Introduction

Malaria remains a serious worldwide health problem due to the emergence and spread of parasite resistance to well-established antimalarial drugs and mosquito vectors resistant to insecticides. In sub-Saharan African populations, malaria is one of the diseases causing most morbidity and mortality. It is estimated that each year malaria causes nearly 800,000 deaths, mostly of African children aged below 5 years. In Burkina Faso, malaria is the leading cause of hospitalisation, with a rate of 50.7% in 2009. Although continued attempts to develop a vaccine for malaria are ongoing, distribution of mosquito nets, household spraying, and prophylaxis remain the primary prevention methods and antimalarial drugs remain the only treatment option. In order to decrease the risk of chemo-resistance to most of the antimalarial drugs, the World Health Organization (WHO) has recommended artemisinin-based combination therapies (ACTs) for the management of uncomplicated P. falciparum malaria cases. Unfortunately, ACT treatment failures have been reported in some countries. In addition, these drugs are expensive, limiting their use in a population with average annual income around $100. Thus the use of traditional and less expensive preparations is common.

Material and methods

This study was approved by the national ethical committee to be conducted with the traditional healers on the study site.
Study site and plants
The study was conducted in the province of Comoe, where malaria transmission is continuous and which covers 15,871 km² with 277,384 inhabitants. With an average annual rainfall of 900 mm, this area is one of the wetter regions of the country, and has a large plant biodiversity. The herbal pharmacopoeia has expanded rapidly in this province, and traditional healers collaborate with researchers in the field of herbal medicine. Twelve samples consisting of leaves and bark from ten plants (Terminalia avicenoides, Combretum colinnum, Ficus capraefolia, Anthochoira nobilis, Celtis integrifolia, Cordia myxa, Lophira lanceolata, Oppilia celtidifolia, Securinega virosa and Tapinanthus dodoneifolius) were identified. The scientific identification and the herbarium were made by botanical taxonomists from the Centre National de Recherche Scientifique et Technologique (CNRST) of Burkina Faso. The specimen voucher number from this herbarium was deposited in Centre National de Recherche et de Formation sur le Paludisme (CNRFp). These parts of plants were used by traditional healers to treat malaria-like symptoms. Samples were harvested during the rainy season, washed, dried and pulverised for phytochemical extractions.

Crude extracts preparation
Extraction based on maceration, decoction and preferential depletion methods were used to obtain five types of extract for each of the 12 plant parts. We obtained three organic extracts, one aqueous with water, and one crude alkaloid. Crude organic extracts were prepared by maceration for 16 hours successively with dichloromethane (CH₂Cl₂), methanol (CH₃OH) and water-methanol (CH₃OH/H₂O) solvents. Plant powder (20 g) was used for these organic extraction methods with 500 mL of each solvent. CH₂Cl₂ extract was air dried at room temperature. CH₃OH and CH₃OH/H₂O extracts were freeze-dried with lyophilisator (Brand) after total evaporation of solvents. Aqueous extracts were prepared by boiling 10 g of plant powder in 500 mL of purified water for 30 minutes. After cooling, solutions were filtered on cotton wool and freeze-dried. Crude alkaloid extracts were obtained by alkalinisation with NH₃OH of the plant powder and extraction with CH₂Cl₂ for 24 hours. Plant powder (20 g) was used by applying the classical alkaloids extraction method. After 16 hours of maceration with ammoniac and CH₂Cl₂, a percolation was made with CH₂Cl₂ solvent. Then 500 mL of dichloromethane layer was concentrated under vacuum and then extracted with a 2% solution of H₂SO₄. The aqueous acid solution was alkalinised again with NH₃OH and extracted with CH₂Cl₂ and a crude alkaloids extract was obtained by concentration.

Each of the 60 extracts was dissolved in appropriate solvent of dimethyl sulfoxide (DMSO) and purified water (DMSO/water) to give a homogeneous solution at an initial concentration of 1 mg/mL. Samples were then serially diluted with complete culture media (RPMI 1640 with albumax) to achieve the required concentration with DMSO concentration < 0.5%.

In vitro antiplasmodial assays
Plasmodium falciparum culture
Sixty extracts were tested for their effectiveness in preventing growth of the most common chloroquine-resistant strain of malaria found in Burkina Faso, Plasmodium falciparum K1. The malaria strains were provided by the London School of Tropical Medicine and Hygiene (England) and were grown under standard conditions as previously described. They were maintained in continuous culture at the CNRFp, in a sterile atmosphere under a laminar flow hood in 200 mL blood group O+ using RPMI 1640 (MegaCell, Sigma Aldrich, USA) medium (5 mL) supplemented with 2-hydroxyethylpiperazine-N-2-ethanesulfonic acid (HEPES acid) (25 mM; Gibco-BRL, Paisley, Scotland), NaHCO₃ (25 mM), 1% Albumax and washed erythrocytes to yield a final haematocrit of 4%. Parasitaemia was maintained between 1% and 6% by dilution with non-infected O+ erythrocytes. Blood was obtained from subjects who had not received antimalarial treatment during the previous two weeks and had an AA electrophoresis (no sickle cell trait). The 75 cm³ culture flasks were incubated for 24 hours at 37 °C in a CO₂ incubator (HeraCell 150, Forma Scientific), with 2% O₂, 5% CO₂, 93% N₂ and 90% humidity. Every 24 hours, supplemented media was renewed and parasitemia was checked by blood smear with optical microscope.

Evaluation of antiplasmodial effect of extracts
Antimalarial effects were quantified with respect to inhibition of parasite growth, as measured by the production of Plasmodium lactate dehydrogenase (pLDH). Testing was performed in three steps in duplicate in 96-well flat bottom plates (TPP, Switzerland).

Malaria parasites were cultured with seven different concentrations of each extract and parasite growth was assessed by the production of pLDH. Each extract was applied in a series of seven duplicate dilutions (final concentrations ranging from 0.78 μg/mL to 50 μg/mL) on two rows. 100 μL of asynchronous parasitised erythrocytes at a hematocrit of 2% with parasitemia between 1.5% and 2% were prepared in 100 μL of each extract. The plates were then placed at 37 °C in a modular incubator chamber with a humidified atmosphere of the same gas mixture as above for 72 hours. Dihydroartemisinin was used to validate the malaria test and chloroquine diphosphate salt (Sigma Aldrich) was used to validate the real chloroquine resistance of malaria strain K1. Infected and uninfected erythrocytes O+ were used as positive and negative controls, respectively. Parasite growth was determined by measuring the content of parasite lactate dehydrogenase using Malstat, NTB/PES reagents. The microplates were read with a spectrophotometer (Biotek EL x 808) at a wavelength of 650 nm. Absorbance data were entered into Microsoft Excel to calculate the percent inhibition relative to positive control from the mean of raw data for each concentration. Table Curve version 5.0 software was used to plot inhibition curves and calculate the inhibition concentration of drug that reduced the pLDH activity by
50% (IC50). The results were categorised following Deharo’s et al classification:19 good antimalarial effect IC50 < 5 µg/mL, moderate antimalarial effect 5 µg/mL ≤ IC50 < 10 µg/mL and inactive extract IC50 ≥ 10 µg/mL.

**In vitro cytotoxicity assay of extracts on human cells**

Human hepatoma cells ATCC # HB-8065 (HepG2) were obtained from the American Type Culture Collection (ATCC, Manassas, USA). The cells were grown in RPMI-1640 (MegaCell, Sigma Aldrich, USA) supplemented with 10% Fetal Bovine Serum (v/v), 1% mix (v/v) of 200 mM L-glutamine, 10 000 IU/mL penicillin and 10 mg/mL streptomycin, (GibcoBRL) within a humidified atmosphere of 6% CO2 and 94% de N2 at 37 °C over 5 days. Cultures were maintained by sub-culturing flasks every 4 days at 5 × 104 cells/25 cm2 flask by trypsinization. The cytotoxicity of the extracts was assessed using a tetrazolium salt MTT (3-[4,5-dimethylthiazol-2-yl]-2.5-diphenyltetrazolium bromide) (Sigma) colorimetric method, based on reagent cleavage by mitochondrial dehydrogenase in viable cells.20 Growing cells were placed at a density of 5 × 104 cells per well in microplates in 100 µL of culture medium. The microplates were incubated in a humidified atmosphere of 6% CO2 and 94% N2 at 37 °C for 24 hours. For each extract, seven duplicate dilutions were prepared with concentrations ranging from 0.78 µg/mL to 50 µg/mL in DMSO and then in medium culture. For each test, we used a growth (cells plus medium only), positive (with doxorubicin) and a negative control (with DMSO) respectively. Cytotoxicity was scored as the percentage reduction in absorbance at 570 nm versus that of the untreated control culture. A selectivity index (SI), corresponding to the ratio between antimalarial and cytotoxic properties, was calculated according to the following formula: SIextract = IC50cytotoxic/IC50malaria. The extract was considered to have negligible cytotoxicity if SI > 1.21

**Results**

**Antimalarial effects**

Among the 60 extracts tested, 21 were identified as having good antimalarial effects (IC50 < 5 µg/mL), 14 with moderate effects (5 µg/mL ≤ IC50 < 10 µg/mL), and 25 as inactive (IC50 ≥ 10 µg/mL) (Table 1). *Terminalia avicenoides* produced the most effective antimalarial extracts, with four coming from its leaves and three from its stem bark (Table 2). Three extracts from *Combretum collinum* and three from *Ficus capraefolia* also had good antimalarial effects (Table 2). Extracts from the seven other plants had mostly moderate to little effect.

**Toxicity**

The extracts with antiplasmodial effects from *Terminalia avicenoides, Combretum collinum* and *Ficus capraefolia*, had low risk of cytotoxicity (SI > 1), with SI ranging from 4 to 140 (Table 1). Higher risk of cytotoxicity (SI < 1) was found with five extracts from four plants: a water-methanol extract from *Cordia myxa* (SI = 0.9 and SI = 0.5, respectively), aqueous extract from *Ficus capraefolia* (SI = 0.4) and water-methanol extract from *Opilia celtidifolia* (SI = 0.4).

**Discussion**

The best antimalarial effects were obtained with extracts of three plants, namely, *Terminalia avicenoides, Combretum collinum* and *Ficus capraefolia*. The four crude extracts from the leaves and three from the stem bark of *Terminalia avicenoides* showed good antimalarial effects against the CQ-resistant strain K1, with IC50 values ranging between 1.16 µg/mL to 4.53 µg/mL. In Nigeria, a similar study showed that methanol extracts of leaves of *Terminalia avicenoides* had an IC50 = 14.09 µg/mL with the K1 malaria strain.22

Based on Deharo’s efficiency criteria, results from Nigeria are different from our findings. These differences may be related to many parameters, including the local environment and the collection periods, which contribute to the variation of plant chemical components as shown in a previous study on seasonal effects on bioactive compounds.23 The biological results could be linked to the laboratory techniques used. In phytochemical studies, extraction methods are often different because the ability of extracting a solvent of chemical groups is related to its polarity. Concerning biological assessment, the results are often based on the sensitivity of techniques used. A previous study done in Australia pointed to the difference of sensitivity of the Flow cytometry assay, the Sybr Green plate reader assay, the Plasmodium falciparum lactate dehydrogenase assay and light microscopy used in *in vitro* antiplasmodial activity assessments.24

Despite the difference of IC50 values obtained, which could be related to laboratory sensitivity techniques and environmental conditions, the antiplasmodial properties of *Terminalia avicenoides* were promising. Our study confirms the pharmacological properties of this plant species shown by its antifungal activity against *Candida albicans*25 and parasitogical activity on *Trypanosoma mali*.26 Another study showed good antidiarrheal properties for an aqueous extract of the roots of *Terminalia avicenoides*.27 It is recommended that future studies should consider this plant as a potential source of antiplasmodial molecules. Our study appears to be the first to demonstrate the antimalarial effects of this plant.

With *Combretum collinum*, dichloromethane, water-methanol and alkaloid extracts of leaves had good antimalarial activity, with IC50 values ranging from 0.2 µg/mL to 2.14 µg/mL. It appears that our findings are the first report of extracts exhibiting *in vitro* antiplasmodial activities. However, studies have shown the pharmacological property of some species of the same botanical family (Combretaceae). Acetone extracts from *Combretum molle*, which belongs to the same botanical family, have shown good antimalarial effects, with IC50 values from 2.2 µg/mL28 to 8.2 µg/mL29 and selective inhibition effect of HIV-1 replication.26 The plant also has antifungal, anti-inflammatory and antiarthritic properties.30,31 According to these results, the antimalarial effect obtained with *Combretum*...
### TABLE 1: In vitro antimalarial and cytotoxic effects of indigenous plant extracts.

| Plant Species (Botanical family) | Local name | Administration method | Plant part | Extract | IC₅₀ (K1) (μg/mL) | Level of antimalarial effect | SI | Level of cytotoxic risk |
|----------------------------------|------------|------------------------|------------|---------|------------------|----------------------------|----|------------------------|
| *Terminalia avicennoides* (Combretaceae) | Kuʻnhil-bliʻngu (G), Kokogo (K) | Oral, Body bath | Leaves | CH₃Cl, CH₃OH | 1.6 | Good | 32.0 | Low |
|                                   |            |                        | Bark       | CH₃OH | 1.9 | Good | 26.2 | Low |
|                                   |            |                        | Bark       | CH₃OH/H₂O | 5.4 | Moderate | 9.2 | Low |
|                                   |            |                        | Bark       | H₂O | 2.6 | Good | 19.4 | Low |
|                                   |            |                        | Bark       | alkaloids | 1.2 | Good | 43.1 | Low |

SI, selectivity index; D, Dioula; G, Goin; T, Turka; K, Karaboro; M, Mossi; B, Bobo.
Level of antimalarial effect: good, IC₅₀ < 5 μg/mL; moderate, 5 μg/mL ≤ IC₅₀ < 10 μg/mL; inactive, IC₅₀ ≥ 10 μg/mL.
Level of cytotoxic risk: low, SI > 1; high, SI < 1.

http://www.ajimonline.org doi:10.4102/ajlm.v2i1.81
collinum can be explained by the presence of chemical groups specific to this botanical family.

*Ficus capraefolia* is the third plant which has good antimalarial effect, with dichloromethane, methanol and crude alkaloid extracts ($IC_{50} < 5 \mu g/mL$) ranging between 0.95 µg/mL and 2.85 µg/mL. Our study appears to be the first report to show the antimalarial activity of this plant. Other studies have shown pharmacological properties of other species of the same botanic family (Moraceae).

Thus, *Ficus sycomorus* (L) had a moderate antimalarial effect with dichloromethane, methanol and crude alkaloid extracts ($IC_{50} < 10 \mu g/mL$) and *Ficus sur* (Forsk) was inactive, with $IC_{50} = 27.4 \mu g/mL$ and $IC_{50} > 100 \mu g/mL$ using chloroquine resistant strains ENT 30 and V1/S respectively. In the other species of Moraceae, which is *Ficus fistulosa* Reiw, molecules such as the flavonoid artonin F, flavonoid 7-demethylartilinol and flavonoid cycloartobiloxanthone have been isolated. The pharmacological effects that our study and others show could be attributed to this chemical group, but a bioguided phytochemical study would be necessary to verify whether it has the same antimalarial molecules as the ones found in our species.

Besides the three previous plant species, *Anthocleista nobilis*, *Opilia celtidifolia*, *Lophira lanceolata*, *Securinega virosa* and *Tapinanthus dodoneifolius* all showed moderate antimalarial activity. A literature search on the antimalarial activities of the aforementioned plants has shown no data. These pharmacological properties could be attributed to alkaloids which could be contained in this plant. Analgesic properties and antibacterial activity of ethanol and methanol extracts have been shown in *Cordia mixa*.

In Kenya, aqueous and methanol extracts from leaves of *Securinega virosa* showed antimalarial activity using the CQ-resistant strain D6 with $IC_{50}$ of 25.52 µg/mL and 2.28 µg/mL respectively. Our study confirms the antimalarial property shown by the Kenyan study, using another CQ-resistant strain K1. Otherwise, this antimalarial effect could be attributed to virosecurinine, an alkaloid isolated from its leaves. Our study appears to be the first report showing a moderate antimalarial effect for *Lophira lanceolata* but its antimicrobial activity against *Candida albicans* has been described previously in Cameroun. In Nigeria, a study showed that a methanol extract of the leaves of *Tapinanthus dodoneifolius* has very good antimicrobial properties.

The promising antimalarial extracts from *Terminalia avicennoides*, *Combretum collinum* and *Ficus capraefolia* showed no cytotoxic effect, with a high selectivity index $> 10$. This finding is in concordance with some cytotoxicity studies of extracts from African medicinal plants. Otherwise, among the extracts which have moderate and no antimalarial effects, the risk of cytotoxicity for human cells has been reported, as shown by water-methanol extracts from *Celtis integrifolia* (SI $> 0.5$), methanol and water-methanol extracts from *Cordia myxa* (respectively SI $= 0.9$ and SI $= 0.5$), aqueous extracts from *Ficus capraefolia* (SI $= 0.4$) and water-methanol extracts from *Opilia celtidifolia* (SI $= 0.4$).

This shows that the toxicity of a drug depends on effective dose used. Furthermore, it is also important that even though they are effective in treating malaria, the cytotoxicity of to these plants must be taken into account especially by traditional healers for whom the major issue is giving the correct dosage. As shown in previous studies, in traditional medicine practice, medicinal plants can be used but the dosage must be taken into consideration. The results of this study can improve the traditional use of plants and protect people from risks following their administration.

It appears for the first time from scientific investigation that *Terminalia avicennoides*, *Ficus capraefolia* and *Combretum collinum* may be potential sources of antimalarial agents due to their good antimalarial effects and the lack of cytotoxic effects of their extracts. The seven other plants have mostly moderate antimalarial effects but some extracts from *Celtis integrifolia*, *Cordial mixa* and *Opilia celtidifolia* showed cytotoxic effects. These plants can be used in traditional medicine by paying close attention to the dosage. The promising results obtained can be a starting point to seek bioactive compounds by bioguided fractionation and biological studies, for the development of new drugs.
