Abstract. Di-hadron correlation measurements have been used to probe di-jet production in collisions at RHIC. A strong suppression of the away-side high-$p_T$ yield in these measurements is direct evidence that high-$p_T$ partons lose energy as they traverse the strongly interacting medium. However, since the momentum of the trigger particle is not a good measure of the jet energy, azimuthal di-hadron correlations have limited sensitivity to the shape of the fragmentation function. We explore the possibility to better constrain the initial parton energy by using clusters of multiple high-$p_T$ hadrons in a narrow cone as the ‘trigger particle’ in the azimuthal correlation analysis. We present first results from this analysis of multi-hadron triggered correlated yields in Au+Au collisions at $\sqrt{s_{NN}} = 200$ GeV from STAR. The results are compared to Pythia calculations, and the implications for energy loss and jet fragmentation are discussed.

1. Introduction

Recent experiments at RHIC have shown that in high-energy heavy-ion collisions, a strongly coupled medium consisting of deconfined quarks and gluons has been produced \cite{1}. This medium is opaque to hard scattered partons, which lose energy as they traverse the medium and subsequently their fragmentation is modified \cite{2}. This fragmentation has been studied using azimuthal correlations of hadrons with large transverse momentum ($p_T$).

Due to the large particle multiplicities observed in heavy-ion collisions, our
current method of measuring jet-like correlations is via di-hadron correlations \[6\]. To characterise parton energy loss, we would like to measure the fragment distribution of hadrons in jets. So far, di-hadron correlations have been used for this purpose, since the large background of soft particles produced in heavy ion collisions makes it difficult to directly reconstruct jets. In these measurements, the transverse momentum of a trigger particle, \(p_{T}^{\text{trig}}\), is used as a proxy for the jet energy, \(E_{T}^{\text{jet}}\). In this paper, we present a new method, using a cluster of multiple high-\(p_{T}\) hadrons as a trigger. Multi-hadron clusters may provide a better measure of the jet energy than than the leading particle \(p_{T}\).

2. Experimental Setup

There are approximately 24M Au+Au events at \(\sqrt{s_{NN}} = 200\) GeV used in this study. They are taken from the data collected during the year 4 run at RHIC, from the 0-12% most central events, selected via STAR’s Zero Degree Calorimeters. Details on the triggering and particle reconstruction are discussed elsewhere \[4\].

3. Analysis and discussion

Charged tracks from primary vertices are used to construct multi-hadron and di-hadron azimuthal distributions. The tracks are selected within the pseudo-rapidity range of \(|\eta| < 1\). The uncorrelated background is removed using the zero yield at minimum (ZYAM) \[5\] method. As elliptic flow \(v_{2}\) is less than a 1% modulation of the background in the ranges selected for \(p_{T}^{\text{trig}}\) and \(p_{T}^{\text{assoc}}\) and the signal to background is much larger than 1%, the elliptic flow modulation is considered negligible.

![Fig. 1. Background subtracted azimuthal distributions for di-hadron triggers (left) and multi-hadron triggers (right) for 12 < \(p_{T}^{\text{trig}}\) < 15 GeV/c and 4.0 GeV/c < \(p_{T}^{\text{assoc}}\) < 5.0 GeV/c. A minimum secondary seed of 3.0 GeV/c is used.]
Azimuthal Correlations with High-$p_T$ Multi-hadron Cluster Triggers

in this analysis.

When forming multi-hadron triggers, all tracks which pass the track quality cuts with $p_T > 5.0$ GeV/c are collected as “primary seeds”. Then within a cone radius ($r = \sqrt{\Delta \phi^2 + \Delta \eta^2}$) of 0.3, all “secondary seeds” which fall above a minimum $p_T$ cut are collected. Minimum secondary seed cuts of 2, 3, and 4 GeV/c have been used for a systematic study. Next, the sum of the primary and secondary seeds is taken to be the trigger $p_T$. To illustrate, a multi-hadron trigger of 12 GeV/c might be a combination of a 6 GeV/c primary seed and two secondary seeds of 3 and 3 GeV/c each, while in the standard di-hadron analysis [6], the trigger would be a single hadron with $p_T = 12$ GeV/c. With the multi-hadron triggers defined, azimuthal difference distributions are calculated between the primary seed in the cone and associated tracks with $p_T$ greater than the minimum secondary seed $p_T$ cut. Representative distributions are shown in Figure 1. For the multi-hadron triggers there is a bias on the near-side due to the algorithm which artificially enhances the yield. With these distributions, recoil (away-side) yields are extracted and studied for various $p_T^{\text{trig}}$ bins.

Random combinations occur in the multi-hadron cluster algorithm. The multi-hadron clusters contain a combinatorial background in which a seed particle from a jet is combined with one or more secondary seeds from the underlying soft event. To study this background, the radial distributions of primary seeds for two different cases are constructed: with associated tracks in the same event and with associated tracks in different events. These distributions are shown in Figure 2 with the open histograms showing same event correlations and the grey filled histograms showing correlations from mixed events, taking the seed track and the secondary seeds

**Fig. 2.** Radial distributions of triggers with associated tracks from the same event (white histograms) and from different events (hatched histograms). Panels from left to right show minimum secondary seed cuts of 2.0, 3.0, and 4.0 GeV/c respectively.
from different events. The background histograms have been scaled to the signal histograms. The secondary seed $p_T$ increases from left to right with $p_T > 2.0, 3.0,$ and $4.0$ GeV/c and the signal-to-background increases from $0.2$ to $0.7$ to $2.0$ respectively. A radius of $0.3$ along with a minimum secondary seed $p_T$ cut greater than $3.0$ GeV/c leads to a reasonable signal to background for this study. Future plans include background subtracted yields calculated with an estimate of background trigger yields.

**Fig. 3.** Recoil yield per trigger for three $p_T$ bins: $10 < p_T^{\text{trig}} < 12$ GeV/c (circles), $12 < p_T^{\text{trig}} < 15$ GeV/c (squares), and $15 < p_T^{\text{trig}} < 18$ GeV/c (triangles). Data is presented on the left (Au+Au), Pythia predictions are presented on the right (p+p). A minimum secondary seed cut of $p_T > 3.0$ GeV/c is applied.

Figures 3 and 4 show recoil (away-side) yields for three $p_T$ bins: $10 < p_T^{\text{trig}} < 12$ GeV/c, $12 < p_T^{\text{trig}} < 15$ GeV/c, and $15 < p_T^{\text{trig}} < 18$ GeV/c respectively. Figure 3 shows a comparison between multi-hadron (open symbols) and di-hadron (solid symbols) triggers with a minimum secondary seed cut of $3.0$ GeV/c for the data (left panels) and Pythia (right panels). The same comparisons are shown in Figure 4 but for a higher minimum secondary seed cut of $4.0$ GeV/c.

The associated per-trigger yields for both single-hadron and multi-hadron triggers in Figures 3 and 4 are similar, suggesting the selection of a similar underlying jet-energy distribution by both methods. The same analysis performed on Pythia events is shown in the right-hand panels of Figures 3 and 4. In the Pythia events,
Azimuthal Correlations with High-$p_T$ Multi-hadron Cluster Triggers

Fig. 4. Recoil yield per trigger for three $p_T$ bins: $10 < p_T^{\text{trig}} < 12$ GeV/$c$ (circles), $12 < p_T^{\text{trig}} < 15$ GeV/$c$ (squares), and $15 < p_T^{\text{trig}} < 18$ GeV/$c$ (triangles). Data is presented on the left (Au+Au), Pythia predictions are presented on the right (p+p). A minimum secondary seed cut of $p_T > 4.0$ GeV/$c$ is applied.

4. Conclusions

This paper has presented first results on the use of multi-hadron triggers investigated as the next step toward full jet reconstruction in heavy-ion collisions. A cone radius of 0.3 coupled with a minimum secondary seed cut greater than 3.0 GeV/$c$ leads to a reasonable signal to background ratio of 0.7. Moreover, the away-side yields for multi-hadron correlations and from di-hadron measurements are consistent. This effect is also reproduced in Pythia simulations. Further analysis of the Pythia events to compare the underlying jet energy selections for di-hadron analysis and multi-hadron triggered analysis is ongoing.
