Abstract

Rationale: Our previous studies demonstrated that bone morphogenetic protein 4 (BMP4) mediated, elevated expression of canonical transient receptor potential (TRPC) largely accounts for the enhanced proliferation in pulmonary arterial smooth muscle cells (PASMCs). In the present study, we sought to determine the signaling pathway through which BMP4 up-regulates TRPC expression.

Methods: We employed recombinant human BMP4 (rhBMP4) to determine the effects of BMP4 on NADPH oxidase 4 (NOX4) and reactive oxygen species (ROS) production in rat distal PASMCs. We also designed small interfering RNA targeting NOX4 (siNOX4) and detected whether NOX4 knockdown affects rhBMP4-induced ROS, TRPC1 and 6 expression, cell proliferation and intracellular Ca2+ determination in PASMCs.

Results: In rhBMP4 treated rat distal PASMCs, NOX4 expression was (226.73±11.13) %, and the mean ROS level was (123.65±1.62) % of that in untreated control cell. siNOX4 transfection significantly reduced rhBMP4-induced elevation of the mean ROS level in PASMCs. Moreover, siNOX4 transfection markedly reduced rhBMP4-induced elevation of TRPC1 and 6 proteins, basal [Ca2+], and SOCE. Furthermore, compared with control group (0.21±0.001), the proliferation of rhBMP4 treated cells was significantly enhanced (0.41±0.001) (P<0.01). However, such increase was attenuated by knockdown of NOX4. Moreover, external ROS (H2O2 100 μM, 24 h) rescued the effects of NOX4 knockdown, which included the declining of TRPC1 and 6 expression, basal intracellular calcium concentration ([Ca2+]i) and store-operated calcium entry (SOCE), suggesting that NOX4 plays as an important mediator in BMP4-induced proliferation and intracellular calcium homeostasis.

Conclusion: These results suggest that BMP4 may increase ROS level, enhance TRPC1 and 6 expression and proliferation by up-regulating NOX4 expression in PASMCs.

Introduction

Pulmonary hypertension (PH) is characterized by increased mean pulmonary arterial pressure (mPAP, at resting condition) > 25 mmHg. PH is a progressively developing disease and eventually leads to right heart failure and death [1]. Many studies have confirmed that vascular stenosis is a main characteristic of PH and is caused by excessive distal small pulmonary arterial remodeling, and further develops into the increase in pulmonary vascular resistance, leads to increased right ventricular overload and eventually causes right ventricular heart failure, even death [1]. Further study demonstrated that ROS (reactive oxygen species) plays an important role in pulmonary vascular proliferation and remodeling in chronic hypoxic pulmonary hypertension (CHPH) [2]. ROS is generated by electrons passing through biological membranes induced by NADPH (nicotinamide-adenine dinucleotide phosphate) oxidase NOX4 [3]. Numerous studies indicated that BMP4 (bone morphogenetic protein 4), a multifunctional ligand which belongs to the transforming growth factor β superfamily, could promote the proliferation, and inhibit the apoptosis of PASMCs [4,5,6,7]. So, BMP4 is thought as a crucial contributor to CHPH development. Others and our previous studies have shown that the hypoxia-elevated proliferation is largely due to enhanced intracellular Ca2+ concentration ([Ca2+]i),
calcium homeostasis and pulmonary vascular remodeling in study aims to clarify the mechanism underlying BMP4 regulating into and explain the mechanisms through which BMP4-induced intracellular calcium homeostasis? 3) whether these mechanisms fit induction controls the downstream TRPC expression and the influence ROS generation and NOX4 expression? 2) whether such 1) whether BMP4, also functions as a multiple faces' factor, could causes elevated pulmonary resistance and PH [6,15]. However, it still remains largely unclear how BMP4 induces TRPCs expres-
sion. Recent studies have confirmed that TGF- abundant expressed in distal pulmonary artery and PASMCs, whereas, TRPC1, TRPC6 expressions are selectively upregulated by hypoxia [8,11,12]. Moreover, it was confirmed that TRPC1 and TRPC6 are essential for the CHPH pathogenesis [13,14]. In PASMCs, BMP4 up-regulates TRPC1 and 6 expressions in rat pulmonary artery and PASMCs to increase [Ca^{2+}], and SOCE, further leads to increased proliferation, which leads to pulmonary small artery spasm contraction and remodeling, and eventually causes elevated pulmonary resistance and PH [6,15]. However, it remains largely unclear how BMP4 induces TRPCs expression. Recent studies have confirmed that TGF-β-induced NOX4 expression and ROS generation were significantly associated with the proliferation of PASMCs [16]. Similarly, we sought to wander: 1) whether BMP4, also functions as a multiple faces' factor, could influence ROS generation and NOX4 expression? 2) whether such induction controls the downstream TRPC expression and the intracellular calcium homeostasis? 3) whether these mechanisms fit into and explain the mechanisms through which BMP4-induced PASMCs proliferation and pulmonary vascular remodeling? This study aims to clarify the mechanism underlying BMP4 regulating calcium homeostasis and pulmonary vascular remodeling in PASMCs, to provide a theoretical basis for the subsequent development of drugs for the treatment.

Materials and Methods

Reagents and Instruments

Sprague Dawley (SD) rats (weight 250 g–300 g) were purchased from Guangdong Experimental Animal Center and housed under standard specific pathogen free (SPF) conditions; All procedures were in accordance with National Institutes of Health guidelines for use of live animals and approved by the Institutional Animal Care and Use Committee (IACUC) of Guangzhou Medical University, Guangzhou, China [License No.; SCXK (Guangdong) 2008–0002]. All surgery was performed under anesthesia with sodium pentobarbital (65 mg/kg i.p.), and all efforts were made to minimize animal suffering.

Fetal bovine serum (FBS), DMEM culture medium was purchased from Hangzhou GINO Co. Ltd, DCFH-DA from Invitrogen Company, BMP4 recombinant protein was purchased from American Genlantis Company. NOX4 siRNA oligo was synthesized by Shanghai GenePharma Co. Ltd. GenSilencer siRNA transfection kit was purchased from American Genlantis Company. MTT reagent and DMSO were purchased from Sigma, U.S., RIPA cell lysates and 30% H₂O₂ from China Biyuntian Biotechnology Institute. Other reagents were of analytical grade products. Flow cytometry Beckman Corporation and full wavelength scanners were purchased from U.S. Thermo Electron Corporation.

PASMCs Culture and Identification

The PASMC culture and identification methods were the common methods used in our study group [11,12].

Recombinant BMP4 Protein Treatment

The primary PASMCs were cultured with 10% FBS DMEM medium until 70–80% confluence. The growth medium was then replaced by 0.5% FBS low glucose DMEM medium to starve for 24 hours. After appropriate starvation, cells were randomly divided into two groups and treated with either vehicle control for the control group or with 50 ng/ml BMP4 recombinant protein for 24 hours.

Detection of Oxygen Free Radicals in PASMCs

After proper culture, the cells were digested by 0.25% trypsin (without EDTA) and collected, then centrifuged at 1000 rpm for 5 minutes and supernatant was discarded. The cells were washed with sterile PBS 1–2 times and suspended with 1 ml PBS solution with 5 μM DCFH-DA. After incubation for 30 minutes at 37°C away from light, samples were centrifuged at 1000 rpm for 5 minutes, washed with sterile PBS for 1–2 times. Cells were finally suspended in 0.5 ml PBS and performed flow cytometry assay. DCFH-DA enters the cells, which, after lipase hydrolysis, becomes DCFH. Non-luminous DCFH breaks into fluorescent substance DCF through oxygen free radicals in the cells. As a result, there is a proportional relationship between DCF fluorescence intensity and the content of oxygen free radicals in cells. DCF excitation wavelength is 488 nm, absorption wavelength 530 nm.

Western blot

After proper culture and treatment, cells were lysed and total protein was extracted by RIPA buffer. To determine cell protein concentration, with α-actin as internal control, 40 μg sample protein from each group was conducted electrophoresis by using 12% SDS-PAGE concentrating gel at 120V for 10 min and separating gel at 150 V for 90 min, transfected by electroporation transfer film in ice, blocked with 5% milk-TBST for 1 hour, and incubated with primary antibody overnight, followed by secondary antibody incubation for 1 hour. Bound antibodies were finally detected using an enhanced chemiluminescence system.

Small interference RNA Transfection

Two pairs of siRNA were synthesized as follows: NOX4-rat-205 (sequence: 5’ AGGAUUGUUGUUUGGAGGATT 3’, 5’ UCGUCGUAAACAAUCCUTT 3’), and NOX4-rat-1048 (sequence: 5’ GACCUGGCAGUAUAUUATT 3’, 5’ AUAAUAUACUGGCCAGGUGU ATT 3’). While designing one pair of test sequences for negative control group (sequence: 5’ UUUUUCGAACGUGUGATT 3’, 5’ ACGUGACAG-GUUCGAAGATT 3’). Primarily cultured cells at 50–70% confluence were transfected with siNOX4 or nontargeting control siRNA using GenSilencer siRNA transfection reagent as carrier for 4 hours in serum-free DMEM in 5% CO₂ at 37°C. The final concentration of each siRNA was 1000 ng/ml. 8 μl 10% FBS was then added and the cells were incubated for 72 hours before protein, flow cytometry, or MTT assay. Recombinant BMP4 Protein (50 ng/ml) and H₂O₂ (100 μM) [17,18] treatment need to be included after siRNA transfection 48 h. Then after 24 h treatment with recombinant BMP4 Protein and H₂O₂, proceed protein and intracellular Ca²⁺ determination experiments.
MTT cell proliferation measurement

Cells were grouped as mentioned above, digested with 0.25% trypsin and dispersed with a medium containing 0.5% FBS to a concentration of 50,000 cells/ml as a single cell suspension. 10,000 cells (200 μl single cell suspension) from each group were seeded in 96-well cell culture plate, with 5 parallel wells for each group. To avoid edge effects, an equal volume of PBS was added around the filled wells in 5% CO₂ incubator at 37°C (within 24 hours). After attachment, discard medium solution and add MTT solution to each well (the final concentration was 5 mg/ml), incubate again in darkness in 5% CO₂ incubator at 37°C for 4–6 hours. Discard supernatant, add 150 μl DMSO to each well, vibrate the plate for 10 minutes until crystalline solid was totally dissolved. Scan and determine the optical density value (Optical density, OD) by Full wavelength scanner at wavelength of 490 nm. Experiments were repeated three times.

Intracellular Ca²⁺ concentration measurement

SOCE was measured in PASMCs using Fura-2 dye and fluorescent microscopy as previously described [6,7,8,19]. To obtain statistically convincing results, the fluorescence intensity was determined in at least 30 cells for each sample.

Statistical Analysis

Gray values were analyzed using ImageJ software. Experimental data, as shown in x±S, were analyzed using statistical software SPSS13.0. Two samples were compared using the t test, multiple groups were compared using univariate analysis of variance (one way-ANOVA) F test, pairwise comparisons between groups using LSD method. P<0.05 was considered statistically significant.

Results

Recombinant BMP4 protein induced NOX4 protein expression and ROS mean level in rat distal PASMCs

Cultured rat distal PASMCs were treated with rhBMP4 or respective vehicle control. The cells without rhBMP4 treatment serve as control group. After 24 hours, expression of NOX4 protein was assessed by western blotting. As shown in Figure 1A and B, the NOX4 protein expressions in cells incubated with the recombinant BMP4 protein (50 ng/ml) for 24 hours were (226.73±11.13)% relative to those in control group (P<0.01), the difference was statistically significant. The ROS mean level in the PASMCs from rhBMP4 treated group and control group was assayed using Flow Cytometry. As shown in Figure 1C, the ROS mean level in cells incubated with the recombinant BMP4 protein (50 ng/ml) for 24 hours was (123.65±1.62)% relative to that in control group (P<0.01), the difference was statistically significant.

NOX4-knockdown abolished BMP4-induced ROS production in rat distal PASMCs

To evaluate the role of NOX4 on BMP4-induced ROS induction in PASMCs, we adopted a loss-of-function approach by knocking down the endogenous expression of NOX4 using its specific siRNA. We firstly synthesized siRNA oligo targeting NOX4 (NOX4-rat-205 siRNA, NOX4-1048 siRNA) and transfected PASMCs to verify the knockdown specificity. Non-targeting siRNA (NC-siRNA) was used as a non-targeting control. As shown in Figure 2A and B, after transfection with NOX4-rat-205 siRNA oligo, NOX4 protein expression decreased to (23.30±1.62)% relative to that in negative control group (P<0.01), the difference was statistically significant. However, in NOX4-1048 siRNA transfected group, NOX4 expression was (95.53±1.51)% relative to that in negative control group (P>0.05). The difference was not statistically significant. We confirmed that NOX4-rat-205 siRNA was the specific NOX4-siRNA. Next, cultured rat distal PASMCs were divided into four groups: 1) NC-siRNA treated group serves as negative control; 2) NC-siRNA transfected plus BMP4 treatment group; 3) NOX4 siRNA transfection group and 4) NOX4 siRNA transfection plus BMP4 treatment group. Afterwards, the ROS mean levels in each group were detected by flow cytometry. As shown in Figure 2C, rhBMP4-treatment after transfection with NC-siRNA, the ROS mean level in rat PASMCs was (130.88±9.36)% relative to that in negative control group (P<0.01), the difference was statistically significant. However, knockdown of NOX4 markedly abolished BMP4 induced ROS mean level, which was (108.29±4.07)% relative to that in negative control group. *P<0.01 compare to NC-siRNA plus BMP4 group. The ROS mean level in those transfected by NOX4-siRNA without BMP4 treatment was (110.63±3.78)% relative to that in negative control. There was no significant difference in ROS levels between negative control siRNA group and NOX4-siRNA transfection group (P>0.05).

Knockdown of NOX4 attenuated BMP4-induced up-regulation of TRPC1 and 6 in rat distal PASMCs

Since previous studies indicated that BMP4 up-regulates the expression of TRPCs in PA and PASMCs, we want to determine whether NOX4 fits into the signaling cascade and mediates the BMP4-induced TRPCs expression. As shown in Figure 3A and B, TRPC1 expression in PASMCs of NOX4 siRNA group was (33.39±5.95)% relative to that in negative control siRNA group (100±0%). We further treated both groups with recombinant BMP4 (50 ng/ml), then assess TRPC1 protein expression by western blotting. As shown in Figure 3 C and D, relative expression of TRPC1 in NOX4-siRNA+BMP4 group was 49.72±6.05% relative to NC-siRNA+BMP4 group. Moreover, TRPC6 showed similar pattern as TRPC1 in the expression level in all the treatment groups: NC-siRNA group, NOX4-siRNA group, NC-siRNA+BMP4 group and NOX4-siRNA+BMP4 group. As shown in Figure 3E, F, G and H, TRPC6 protein expressions in NOX4-siRNA transfected PASMCs was 27.01±5.33% relative to that in NC-siRNA control, with a statistically significant difference (P<0.01). TRPC6 protein expression in NOX4-siRNA group was (61.19±2.33)% also markedly lower than that in NC-siRNA group (100±0%), which had a statistically significant difference (P<0.01). It indicated that NOX4 mediates BMP4-induced TRPC1 and TRPC6 protein expression.

Knockdown of NOX4 blocked BMP4-induced proliferation in rat distal PASMCs

We further observed the effect of NOX4 on the proliferation of PASMCs. As shown in Figure 4 A, B and C, the absorbance values at wavelength of 490 nm in control group and BMP4 group were 0.21±0.001, 0.41±0.01 respectively. Compared with that in control group, there was a statistically significant increase in BMP4 group (treatment with recombinant BMP4 for 24 hours, P<0.01). After transfection with negative control siRNA and NOX4-siRNA, the absorbance values at wavelength of 490 nm were 0.57±0.01 and 0.24±0.03 respectively. However, when treated with recombinant BMP4 for 24 hours after transfection, the absorbance values of PASMCs at wavelength of 490 nm were 0.67±0.01 and 0.48±0.01 respectively. It indicated that compared with control group, knockdown of NOX4 significantly inhibits PASMCs proliferation (P<0.01). However, BMP4 did not
reverse this process. After NOX4 knockdown and recombinant BMP4 treatment, cell proliferation was still significantly inhibited, relative to that in control group (P, 0.01).

Knockdown of NOX4 inhibited BMP4-induced increase of basal [Ca²⁺] and SOCE in rat distal PASMCs

Since NOX4-siRNA can block BMP4-induced TRPC1 and 6 protein expression, we then sought to figure out whether NOX4-siRNA inhibits TRPC1 and 6 activity in their SOCE mediation major and the intracellular Ca²⁺ regulation. As shown in Figure 5A, B and C, after transfection with NC-siRNA, pre-treatment with rhBMP4 (50 ng/ml) increased basal [Ca²⁺]i (141.18 ± 5.85 nM) and SOCE (102.39 ± 8.48 nM) in rat distal PASMCs, compared with NC-siRNA without BMP4 treatment group (111.43 ± 2.63 nM, 60.79 ± 5.20 nM), and this had a statistically significant difference (P<0.01). However when transfection with NOX4-siRNA, basal [Ca²⁺]i and SOCE were 83.91 ± 5.94 nM and 40.70 ± 2.02 nM respectively, which obviously decreased compared with NC-siRNA group, and the difference was statistically significant (P<0.01). These results were not altered after pre-treatment with rhBMP4 in NOX4-siRNA group (85.45 ± 5.80 nM, 41.64 ± 3.69 nM), suggesting BMP4 regulates intracellular Ca²⁺ homeostasis through altering NOX4.

External ROS rescues the effects of NOX4 knockdown in rat distal PASMCs

From all the results above, we knew that knockdown of NOX4 abolished BMP4-induced ROS generation and TRPC expression. So, what happen when external ROS are involved? As shown in Figure 6A, B, C and D, transfection with NOX4-siRNA TRPC1 and TRPC6 protein expression in PASMCs were (56.58 ± 5.36) % and (51.23 ± 10.58) % respectively, relative to that in NC-siRNA group ((100 ± 0) % and (100 ± 0) %). But pretreatment with H₂O₂ (100 μM) reversed this effect, TRPC1 and TRPC6 expression in NOX4-siRNA + H₂O₂ group were (89.60 ± 2.58) % and (87.08 ± 2.68) %, relative to NC-siRNA group. Moreover, we tested basal [Ca²⁺], and SOCE in NC-siRNA group, NOX4-siRNA group and NC-siRNA+ H₂O₂ group respectively. As shown in Figure 6E, F and G, basal [Ca²⁺], and SOCE in NC-siRNA group, NOX4-siRNA group and NC-siRNA+ H₂O₂ group were 110.16 ± 3.30 nM and 60.59 ± 5.43 nM. However, the NOX4-siRNA group were 83.76 ± 3.82 nM and 35.76 ± 5.44 nM, and their difference was statistically significant.
Contrast with NOX4-siRNA group, the basal $[\text{Ca}^{2+}]_i$ and SOCE of NC-siRNA $+ \text{H}_2\text{O}_2$ group increased into $139.89 \pm 4.40 \text{nM}$ and $99.16 \pm 9.58 \text{nM}$, which had a statistically significant ($P<0.01$).

**Discussion**

In this study, we found that rhBMP4 increased NOX4 protein expression and ROS mean level in rat distal PASMCs, and further investigated the role of NOX4 with a loss of function strategy using siRNA. To confirm whether NOX4 regulated intracellular $\text{Ca}^{2+}$ homeostasis via affecting ROS generation, we applied external ROS ($\text{H}_2\text{O}_2$) to rescue the ROS level, under the condition of NOX4 knockdown. Our results showed that rhBMP4-induced ROS generation and TRPCs protein up-regulation, basal $[\text{Ca}^{2+}]_i$ and SOCE increase, as well as excessive cell proliferation, are dependent on BMP4-induced NOX4 expression.

During the recent years, proportional BMPRII gene mutation has been found in idiopathic pulmonary arterial hypertension (IPAH) and HPAH (familial PAH) patients in Chinese Han people [20]. Further studies have revealed that combination of BMP with BMPRI and BMPRII may cause dependent phosphorylation of the receptor of cytosolic inhibitors–Smad1, Smad5, Smad8. Phosphorylated Smads then interact with the co-Smad, Smad4, regulate the target gene transcription, including Smad binding sequence [21,22]. Xudong Yang, etc. [4] found that BMP4 plays a key regulatory role in the proliferation of the PASMCs isolated from patients with familial pulmonary hypertension via p38MAPK and ERK1/2 signaling pathway. L. Dewachter, etc. [23] confirmed that in idiopathic pulmonary hypertension, BMP4 promotes PASMCs mitosis through Smad and p38MAPK pathway. Our previous study [6] has found that BMP4 can induce TRPC1 and 6 up-regulation by activating the p38MAPK and ERK1/2 pathway in PASMCs, promoting SOCE through activating TRPC channels and increasing basal $[\text{Ca}^{2+}]_i$, thus contributing to pulmonary vasoconstriction and PASMCs proliferation, eventually leading to pulmonary vascular remodeling in rats. In the present study, we further confirmed that recombinant...
Figure 3. NOX4 knockdown decreased TRPC1 and TRPC6 expression under both control and BMP4 treatment circumstances. BMP4 protein (50 ng/ml) could promote the expression of TRPC1 and 6, basal \([\text{Ca}^{2+}]_i\), SOCE and the proliferation of rat distal PASMCs.

Then, we sought to determine through which signaling pathway does BMP4 induce TRPC1 and 6 expressions, alter intracellular calcium homeostasis and cell proliferation. Many studies focusing on the endothelial function revealed a tight relationship among BMP4, NOX4 and ROS. Xiao Yu Tian, etc. confirmed that BMP4 leads to endothelial cell apoptosis through NADPH oxidase/ROS/p38MAPK/JNK pathway [24]. By using small interfering RNA gene silencing BMP4, the shear stress-induced release of ROS in endothelial cells was inhibited, which is mainly caused by NOX1 [25]. In addition, compared with the low-fat diet, high-fat diet could increase NOX4 protein and increase its signaling pathway upstream BMP4 expressions in C57BL/6 mouse thoracic aorta tissue [26]. These results indicated that BMP4 plays an important role in regulating NOX4 and ROS levels. We firstly tested whether BMP4 promotes NOX4 and ROS levels in rat distal PASMCs. Results showed that NOX4 and ROS were increased by BMP4 treatment and the increased ROS level...
could be attenuated through interfering endogenous NOX4 gene using siRNA knockdown. This indicates that in PASMCs, BMP4 increased ROS generation, at least in part, is mediated by NOX4. ROS plays an important role in occurrence and development of CPH, mainly in the following three aspects: 1) regulates proliferation and apoptosis activity; 2) participates in pulmonary artery smooth muscle contraction; 3) regulates hypoxic pulmonary vascular remodeling. This study confirmed that NOX4, the highest expressed NADPH oxidase in PASMCs, plays a role in electron transfer in the process of hypoxia-induced increase in ROS levels. In the lung tissue specimens of patients with idiopathic pulmonary hypertension, NOX4 was significantly increased, mainly localized in the blood vessel membranes. After using small interfering RNA to knockdown NOX4, the proliferation of PASMCs was inhibited and ROS level was decreased. This indicated that NOX4, as an important factor, is involved in pulmonary vascular remodeling during pulmonary hypertension development [27]. Talija Djordjevic, etc. confirmed that the proliferation of human PASMCs is associated with NADPH oxidase, and the role is mainly acted by NADPH oxidase NOX4 [28]. Isabel Diebold, etc. also found that in hypoxia-induced PASMCs proliferation, there are NOX4 up-regulation and increased ROS levels [29]. In addition, by using Mn-TBAP to clear whether ROS can reverse hypoxia-induced PASMCs proliferation, there are NOX4 up-regulation and increased ROS levels [30]. The hydrogen peroxide can promote cell proliferation by regulating calcium homeostasis in PASMCs [31]. Our results consistently showed that BMP4 up-regulated ROS level and proliferation of rat PASMCs, and NOX4 knockdown significantly reduced BMP4 increased ROS production and cell proliferation. These results suggest that NOX4 has a proportional relationship with ROS levels, and ROS plays a key role in regulating the proliferation and differentiation of PASMCs. However, in rat distal PASMCs, it remains unclear through which signaling pathways do NOX4 and ROS regulate intracel-
