I. INTRODUCTION

From the discovery of the BTZ black hole solution [1], there has been an increasing interest for black hole physics in three dimensions. This interest has taken much bigger proportion the last two decades in part because of their implication in the context of AdS/CFT correspondence. Indeed, it is now well accepted that three-dimensional gravity is an excellent laboratory in order to explore and test some of the ideas behind the AdS/CFT correspondence [2]. In contrast with the four-dimensional case, the existence of the BTZ black hole in three dimensions is inherent to the presence of the negative cosmological constant and due to the lack of local degrees of freedom in pure Einstein gravity in three dimensions it is the global structure of this solution what provides it’s non-triviality. A way to circumvent this behavior was proposed long time ago in [3] by adding to the standard Einstein-Hilbert action a Chern-Simons term built out of the connection. In second order formulation, the result-}

|<|
In the present work, we establish that new massive gravity in three dimensions may also accommodate black hole solutions with a source given by a (non)minimally coupled and self-interacting scalar field whose action reads

$$S_M = - \int d^3x \sqrt{-g} \left[ \frac{1}{2} \partial_{\mu} \Phi \partial^{\mu} \Phi + \frac{\xi}{2} R \Phi^2 + \frac{M}{2} \Phi^2 + \frac{\lambda}{4!} \Phi^4 \right].$$

Here, $\xi \geq 0$ denotes the nonminimal coupling parameter, $R$ the scalar curvature, $M$ is a constant identified as part of the mass of the scalar field and $\lambda$ is the coupling constant of the potential $\Phi^4$. The field equations obtained by varying the action $S_{\text{NMG}} + S_M$ read

$$G_{\mu \nu} + \Lambda g_{\mu \nu} - \frac{1}{2m^2} K_{\mu \nu} = T_{\mu \nu}, \quad (2a)$$

$$\Box \Phi = \xi R \Phi + M \Phi + \frac{\lambda}{3!} \Phi^3, \quad (2b)$$

where we have defined

$$K_{\mu \nu} = 2R_{\mu \nu} - \frac{1}{2} \nabla_{\mu} \nabla_{\nu} R - \frac{1}{2} R g_{\mu \nu} + 4R_{\mu \alpha \nu \beta} R^{\alpha \beta} - \frac{3}{2} R R_{\mu \nu} - R_{\alpha \beta} R^{\alpha \beta} g_{\mu \nu} + \frac{3}{8} R^2 g_{\mu \nu}. \quad (3)$$

and the stress tensor is given by

$$T_{\mu \nu} = \partial_{\mu} \Phi \partial_{\nu} \Phi - g_{\mu \nu} \left( \frac{1}{2} \partial_{\sigma} \Phi \partial^{\sigma} \Phi + \frac{M}{2} \Phi^2 + \frac{\lambda}{4!} \Phi^4 \right) + \xi (g_{\mu \nu} \Box - \nabla_{\mu} \nabla_{\nu} + G_{\mu \nu}) \Phi^2. \quad (4)$$

II. ASYMPTOTICALLY ADS BLACK HOLE SOLUTIONS

A black hole solution of the field equations (2a,b) is given by

$$ds^2 = - F(r) dt^2 + \frac{dr^2}{F(r)} + r^2 d\Omega^2, \quad (6a)$$

$$F(r) = \frac{r^2}{l^2} - c_1 \left( \frac{32}{256} \frac{\xi}{32 - \xi} \right)^{\frac{7}{4}}, \quad (6b)$$

$$\Phi(r) = \frac{1}{r} \left( \frac{r}{l} \right)^{\frac{32}{\xi} \left( \frac{32}{\xi} - \frac{3}{2} \right)} \int \frac{8c_1 (32 \xi - 5)}{256 \xi^2 - 32 \xi - 1}, \quad (6c)$$

where $c_1$ is an arbitrary integration constant, and the cosmological term in the action $\Lambda$, the self-interaction coupling $\lambda$, the graviton mass and the scalar field mass are fixed as $\Lambda = \frac{4}{l^4}$, $\lambda = \frac{32}{l^2}$, $M = \frac{1}{l^2}$ and $\xi = \frac{32}{l^2}$ are excluded from this family.

Imposeing the absence of naked singularities at infinity implies that the coupling $\xi$ must be restricted such that the leading term in the lapse should be $r^2$ (therefore fixing an asymptotically AdS behaviour). As a consequence, the scalar field vanishes at infinity. Requiring in addition the existence of an event horizon, finally implies that the range of physically allowed values of $\xi$ is

$$\xi \in \left[ 0, \frac{1}{16} \left( 1 + \sqrt{2} \right) \right] \cup \left[ 5 \frac{32}{l^2}, \frac{3}{16} \right]. \quad (8)$$

Clearly the strength of the subleading term in the metric strongly depends on the value of the nonminimal coupling parameter $\xi$.

The horizon is located at $r = r_+ = l c_1^{3/16 - \xi}$ while the Hawking temperature of these solutions is given by

$$T_H = \frac{c_1^{3/16 - \xi}}{4 \pi l (3 - 16 \xi)}. \quad (9)$$

The Wald formula for the entropy $S$, being proportional to the lapse metric function evaluated at the horizon yields a zero entropy

$$S \propto \left( 1 - c_1 \left( \frac{r}{l} \right)^{\frac{16\xi - 3}{16\xi}} \right)_{r = r_+} = 0. \quad (10)$$

Note that zero entropy black hole solutions with planar horizon have also been found for scalar fields nonminimally coupled with the general Lovelock gravity in arbitrary dimension in [19]. Assuming that the first law of thermodynamics holds, implies that the solutions in our family have zero mass. As a consequence, one may interpret the unique integration constant $c_1$ as a gravitational hair.

To conclude this section, let us analyze in more detail the solutions obtained for some relevant particular values of $\xi$. 

...
It is remarkable to note that we are allowed to consider the minimally coupled case ($\xi = 0$), and therefore conclude that the existence of these solutions is not inherent to the presence of the nonminimal coupling $R \Phi^2$ in the action as it is the case for example in four dimensions, [24, 22]. For this case the metric reduces to
\[ ds^2 = - \left( \frac{r^2}{l^2} - c_1 \frac{r^{5/3}}{l^{5/3}} \right) dt^2 + \frac{dr^2}{l^2 - c_1 \frac{r^{5/3}}{l^{5/3}}} + r^2 d\phi^2, \] (11)
and the values for the couplings can be read from equation (6c) while the expression for the field is obtained from (6c) by fixing $\xi = 0$.

When $\xi = \frac{1}{2}$, the scalar field becomes massless $M = 0$ and not self-interacting $\lambda = 0$, giving indeed a conformal invariant matter source. The remaining parameters take the values $\Lambda = m^2 = -\frac{1}{2}$ while the metric reduces to
\[ ds^2 = - \left( \frac{r^2}{l^2} - c_1 \frac{r}{l} \right) dt^2 + \frac{dr^2}{l^2 - c_1 \frac{r}{l}} + r^2 d\phi^2. \] (12)

The expression for the field can be read as well from (6b) by setting $\xi = \frac{1}{4}$. This solution is a particular case of the asymptotically AdS black hole found in the absence of sources for new massive gravity [3, 23]. In other words, for the conformal coupling $\xi = \frac{1}{4}$, the black hole becomes a particular solution of the field equations [2] for which both sides (the gravity and the source parts) vanish identically.

\[ G_{\mu\nu} + \Lambda g_{\mu\nu} - \frac{1}{2m^2} K_{\mu\nu} = 0 = T_{\mu\nu}. \]

This kind of black hole configurations were discussed in [24] and dubbed stealth. Note that this stealth solution corresponds to a particular case of the one found in [25].

We now show that the same field equations [2] may also accommodate Lifshitz black hole solutions for a different region of the parameters as it occurs in the source free case with the AdS solution [3] and the $z = 3$ Lifshitz solution [10].

III. ASYMPTOTICALLY LIFSHITZ BLACK HOLE SOLUTIONS

There are three branches of solutions with Lifshitz asymptotic for the above equations of motion [3]. In all of them the solutions have the following generic form
\[ ds^2 = r^{2z} \left( 1 - \frac{c_1}{r^\chi} \right) dt^2 + \frac{dr^2}{r^2 \left( 1 - \frac{c_1}{r^\chi} \right)} + r^2 d\phi^2, \]
\[ \Phi(r) = \frac{\sqrt{\lambda}}{r^{\chi/2}}, \] (13)
with the cosmological term and the graviton mass parameterized in term of the dynamical exponent as
\[ \Lambda = -\frac{1}{2} (z^2 + z + 1), \quad m^2 = -\frac{1}{2} (z^2 - 3z + 1), \] (14)
where from now on we set $l = 1$. The different branches share basically the same features than those discussed in the AdS case, and are presented with some detail below.

A. $\chi = (z + 1)$

For $\chi = (z + 1)$, there exists a Lifshitz black hole solution where the parameters are fixed as follows
\[ \xi = \frac{5}{32}, \quad \alpha = \frac{16c_1 (1 - z)}{z^2 - 3z + 1}, \]
\[ M = \frac{1}{16} (z^2 - 3z + 1), \]
\[ \lambda = \frac{3(z^2 - 3z + 1)(8z^2 + 11z + 13)}{256(z - 1)}. \] (15)

In order to deal with a real scalar field, the constant $c_1$ must be strictly positive and the existence of a horizon is ensured for
\[ z \in \left[ 0, \frac{3 - \sqrt{5}}{2}, \frac{3 + \sqrt{5}}{2} \right]. \]

As in the previous sections the other values at the boundaries of the intervals are excluded from this family of solutions.

B. $\chi = 2(z - 1)$

The second family of Lifshitz black hole solutions is only valid for $z \geq 1$ in order to have the correct Lifshitz asymptotic, and the parameters take the following form
\[ \xi = \frac{2z - 1}{4(3z - 1)}, \quad \alpha = \frac{4c_1 (1 - 3z)}{z^2 - 3z + 1}, \]
\[ M = \frac{(2z - 5)(z^2 - 3z + 1)}{6z - 2}, \]
\[ \lambda = \frac{3(z^2 - 3z + 1)(12z^3 - 44z^2 + 43z - 13)}{4(1 - 3z)^2}. \] (16)

As in previous case, in order to ensure a well behaved spacetime at infinity as well as having an event horizon, the dynamical exponent must belong to the following range
\[ z \in \left[ 1, \frac{3 + \sqrt{5}}{2} \right]. \]

C. $\chi = \frac{1}{2}(z + 1)$

The last class of solutions is given for $\chi = \frac{1}{2}(z + 1)$ with
\[ \xi = \frac{3z^2 - 4z + 3}{2(9z^2 - 12z + 11)}, \]
\[ \alpha = \frac{c_1 (z - 3)(9z^2 - 12z + 11)}{2(z - 1)(z^2 - 3z + 1)}, \]
\[ M = \frac{(z - 1)(21z^2 - 13z^2 + 31z - 15)}{16(9z^2 - 12z - 11)}, \]
\[ \lambda = -\frac{3(z - 1)^3(z^2 - 3z + 1)(9z^2 - 12z - 19)}{4(z - 3)(9z^2 - 12z - 11)^2}. \]

The dynamical exponent falls within the following range
\[ z \in \left[ 0, \frac{3 - \sqrt{5}}{2}, \frac{3 + \sqrt{5}}{2} \right], \] (17)
where $\lambda = 0$.

In contrast with the previous cases, here there is wider range of possible values for the dynamical exponent. Note that none
of these three classes of solutions accomodate a stealth with $z = 3$ as it was the case for the asymptotically AdS solution. As a last comment we also notice that minimally coupled scalar fields are not allowed in the Lifshitz case.

IV. CONCLUSIONS

In this note, we have reported two classes of black hole solutions of new massive gravity in three dimensions with a source described in term of a self-interacting and massive scalar field (non)minimally coupled. The first metric family corresponds to an asymptotically AdS black hole in a specific region of the coupling constants which are all parameterized in terms of $\xi$. As in the free source case, we have shown that the same equations also admit Lifshitz black hole solutions for a different set of the parameters expressed in this case in term of the dynamical exponent $z$. It is somehow appealing that the equations of new massive gravity with or without source may accommodate such classes of black holes with different asymptotic behavior. It is also surprising that the matter source that has made possible the construction of these black hole solutions is quite simple. Indeed, it involves a scalar field $\Phi$ that can be massive, (non)minimally coupled and the self-interacting potential is a physical one $U \propto \Phi^4$. We have also computed the Wald formula for the entropy and realized that it is proportional to the lapse metric function evaluated at the horizon. As a consequence, the Wald entropy vanishes identically in spite of the fact that the solutions have a non zero temperature. We have not computed the mass since imposing that the first law of thermodynamics holds, this would yield to a zero mass. Indeed, in Ref. [13], there were obtained planar black hole solutions for Lovelock gravity with a scalar field nonminimally coupled which as well have zero entropy when computed using Wald's formula. In this case, using the Euclidean formalism, it was explicitly shown that the mass indeed vanishes. Independently, it will be nice to provide a complete thermodynamics analysis of the solutions here derived. Also it will be desirable to understand the physical meaning of these solutions which have a zero entropy. It seems that it is due to the presence of higher-order curvature terms as well as to the fact that the transverse section of these solutions is planar. The scalar field found here is static in both families of solutions, hence a rotating version of the AdS black hole solution can easily be obtained by operating with an improper boost in the $(t - \psi)$-plane. This trick will also work in the case of the Lifshitz black hole with the difference that the spinning version of the Lifshitz black hole will violate the Lifshitz isometry at infinity. In three dimensions, solitons can easily be constructed from static black holes by operating a double Wick rotation. In the case of Lifshitz black holes with dynamical exponent $z$, the corresponding soliton will enjoy the Lifshitz anisotropy asymptotically with a dynamical exponent $z^{-1}$. These solitons may be useful to better understand the thermodynamics issue of the solutions presented here. Indeed, in Ref. [20], the authors proposed a generalization of the Cardy formula in order to compute the semiclassical entropy of Lifshitz black hole with dynamical exponent $z$, and in this formula, the ground state is played by the soliton with dynamical exponent $z^{-1}$.
