(Dated: May 17, 2018)

Making use of the T-duality symmetry of superstring theory, and of the double geometry from Double Field Theory, we argue that cosmological singularities of a homogeneous and isotropic universe disappear. In fact, an apparent big bang singularity in Einstein gravity corresponds to a universe expanding to infinite size in the dual dimensions.

I. INTRODUCTION

The singularities which arise at the beginning of time in both standard and inflationary cosmology indicate that the theories which are being used in cosmology break down as the singularity is approached. If space-time is described by Einstein gravity and matter obeys energy conditions which are natural from the point of view of point particle theories, then singularities in homogeneous and isotropic cosmology are unavoidable [1]. These theorems in fact extend to inflationary cosmology [2–4].

But we know that Einstein gravity coupled to point particle matter cannot be the correct description of nature. The quantum structure of matter is not consistent with a classical description of space-time. The early universe needs to be described by a theory which can unify space-time and matter at a quantum level. Superstring theory (see e.g. [5, 6] for a detailed overview) is a promising candidate for a quantum theory of all forces of nature. At least at the string perturbative level, the building blocks of string theory are fundamental strings. Strings have degrees of freedom and new symmetries which point particle theories do not have, and these features may lead to a radically different picture of the very early universe, as discussed many years ago in [7] (see also [8]).

As discussed in [7], string thermodynamic considerations indicate that the the cosmological evolution in the context of string theory should be nonsingular. A key realization is that the temperature of a gas of closed string in thermal equilibrium cannot exceed a limiting value, the Hagedorn temperature [9]. In fact, as reviewed in the following section, the temperature of a gas of closed strings in a box of radius $R$ decreases as $R$ becomes much smaller than the string length. If the entropy of the string gas is large, then the range of values of $R$ for which the temperature is close to the Hagedorn temperature $T_H$ is large. This is called the Hagedorn phase of string cosmology. The exit from the Hagedorn phase is smooth and is a consequence of the decay of string winding modes into string loops [1]. The transition leads directly to the radiation phase of Standard Big Bang cosmology (see [11] for reviews of the String Gas Cosmology scenario).

If strings in the Hagedorn phase are in thermal equilibrium, then the thermal fluctuations of the energy-momentum tensor can be computed using the methods of [12]. In particular, it can be shown that in a compact space with stable winding modes the specific heat capacity has holographic scaling as a function of the radius of the volume being considered. As a consequence of this, thermal fluctuations of strings in the Hagedorn phase lead to a scale-invariant spectrum of cosmological perturbations at late times, with a slight red tilt like what is predicted in inflationary cosmology. If the string scale is comparable to the scale of particle physics Grand Unification the predicted amplitude of the fluctuations matches the observations well (see [16] for recent observational results). Hence, String Gas Cosmology provides an alternative to cosmological inflation as a theory for the origin of structure in the Universe. The predicted spectrum of gravitational waves [17] is also scale-invariant, but a slight blue tilt is predicted, in contrast to the prediction in standard inflationary cosmology. This is a prediction by means of which the scenario can be distinguished from standard inflation (meaning inflation in Einstein gravity driven by a matter field obeying the usual energy conditions). A simple modelling of the transition between the Hagedorn phase and the radiation phase leads to a running of the spectrum which is parametrically larger than what is obtained in simple inflationary models [18].

In this paper, we will study the cosmological background dynamics which follow from string theory if the target space has stable winding modes. An example where this is the case is a spatial torus. We will argue that from the point of view of string theory the dynamics is non-singular.

1 This mechanism suggests that exactly three spatial dimensions can become large [7], the others being confined to the string length by the interaction of the string winding and momentum modes [10].
II. DUAL SPACE FROM T-DUALITY

For simplicity let us assume that space is toroidal with \( d = 9 \) spatial dimensions, all of radius \( R \). Closed strings then have momentum modes whose energies are quantized in units of \( 1/R \)

\[
E_n = \frac{n}{R},
\]

where \( n \) is an integer. They also have winding modes whose energies are quantized in units of \( R \), i.e.

\[
E_m = mR,
\]

where \( m \) is an integer and we are working in units where the string length is one. Strings also have a tower of oscillatory modes whose energies are independent of \( R \). The number of oscillatory modes increases exponentially with energy.

It follows from (1) and (2) that the spectrum of string states is invariant under the T-duality transformation

\[
R \rightarrow \frac{1}{R}
\]

if the momentum and winding numbers are interchanged. The transformation (3) is also a symmetry of the string interactions, and is assumed to be a symmetry of string theory beyond perturbation theory (see e.g. [6])

As is well known, the position eigenstates \( |x\rangle \) are dual to momentum eigenstates \( |p\rangle \). In a compact space, the momenta are discrete, labelled by integers \( n \), and hence

\[
|x\rangle = \sum_n e^{inx} |n\rangle.
\]

where \( |n\rangle \) is the momentum eigenstate with momentum quantum number \( n \). As already discussed in [7], in our string theory setting, windings are T-dual to momenta, and we can define a T-dual position operator

\[
|\tilde{x}\rangle = \sum_m e^{im\tilde{x}} |m\rangle,
\]

where \( |m\rangle \) are the eigenstates of winding, labelled by an integer \( m \).

As again argued in [7], experimentalists will measure physical length in terms of the position operators which are the lightest. Thus, for \( R > 1 \) (in string units), it is the regular position operators \( |x\rangle \) which determine physical length, whereas for \( R < 1 \) it is the dual variables \( |\tilde{x}\rangle \). Hence, the physical length \( l_p(R) \) is given by

\[
l(R) = R \quad \text{for} \quad R \gg 1,
\]

\[
l(R) = \frac{1}{R} \quad \text{for} \quad R \ll 1.
\]

As was argued in [7], in String Gas Cosmology the temperature singularity of the Big Bang is automatically resolved. If we imagine the radius \( R(t) \) decreasing from some initially very large value (large compared to the string length), and matter is taken to be a gas of super-strings, then the temperature \( T \) will initially increase, since for large values of \( R \) most of the energy of the system is in the light modes, which are the momentum modes, and the energy of these modes increases as \( R \) decreases. Before \( T \) reaches the maximal temperature \( T_H \), the increase in \( T \) levels off since the energy can now go into producing oscillatory modes. For \( R < 1 \) (in string units) the energy will flow into the winding modes which are now the light modes. Hence,

\[
T(R) = T\left(\frac{1}{R}\right).
\]

A sketch of the temperature evolution as a function of \( R \) is shown in Figure 1. As a function of \( \ln R \) the curve is symmetric as a reflection of the symmetry (7). The region of \( R \) when the temperature is close to \( T_H \) and the curve in Fig. 1 is approximately horizontal is called the “Hagedorn phase”. Its extent is determined by the total entropy of the system [7].

![FIG. 1: T versus log R for type II superstrings. Different curves are obtained for different entropy values, which is fixed. The larger the entropy the larger the plateau, given by the Hagedorn temperature. For \( R = 1 \) we have the self-dual point.](image-url)

III. COSMOLOGICAL DYNAMICS AND DUAL SPACE-TIME

In the following we will couple a gas of strings to a background appropriate to string theory. Since the massless modes of string theory include, in addition to the graviton, the dilaton and an antisymmetric tensor field, a cosmological background will contain the metric, the dilaton and the antisymmetric tensor field. For a homogeneous and isotropic cosmology the metric can be written as

\[
ds^2 = -dt^2 + a(t)^2 d\mathbf{x}^2,
\]
where \( \alpha = 1 \) is the cosmological scale factor and \( \mathbf{x} \) are comoving spatial coordinates. We have assumed vanishing spatial curvature for simplicity. We denote the dilaton by \( \phi(t) \).

The T-duality symmetry of string theory leads to an important symmetry of the massless background fields, the \textit{scale factor duality} [20]. In the absence of an antisymmetric tensor field these take the form

\[
\begin{align*}
\alpha(t) & \rightarrow \frac{1}{\alpha(t)} \quad (9) \\
\tilde{\phi}(t) & \rightarrow \tilde{\phi}(t)
\end{align*}
\]

where the T-duality invariant combination of the scale factor and the dilaton is

\[
\tilde{\phi} \equiv \phi - d \ln a,
\]

where \( d = D - 1 \) is the number of spatial dimensions and \( D \) the number of space-time dimensions.

The background equations of motion are those of dilaton gravity (we will neglect the antisymmetric tensor field). In the absence of matter, these equations were studied in detailed in the context of Pre-Big-Bang cosmology [20]. In the presence of string matter, they have been analyzed in [21]. The equations in the presence of a gas of matter described by energy density \( \rho \) and pressure \( p \) are

\[
\begin{align*}
\left( \dot{\phi} - dH \right)^2 - dH^2 &= e^{\phi} \rho \quad (11) \\
H - H \left( \dot{\phi} - dH \right) &= \frac{1}{2} e^{\phi} p \\
2 \left( \ddot{\phi} - d\dot{H} \right) - \left( \dot{\phi} - dH \right)^2 - dH^2 &= 0, \quad (13)
\end{align*}
\]

where \( H \equiv \dot{a}/a \). These are the equations in the string frame. In particular, we can combine these equations to write a continuity equation,

\[
\dot{\rho} + (D - 1)H(\rho + p) = 0. \quad (14)
\]

We consider matter to be a gas of strings. For \( R \gg 1 \) most of the energy is in the momentum modes which act as radiation and hence have an equation of state parameter \( w \equiv p/\rho \) given by \( w = 1/d \). For \( R \ll 1 \), however, most of the energy density is in the winding modes whose equation of state parameter is \( w = -1/d \). Finally, for \( R = 1 \) the equation of state is \( w = 0 \). An interpolating form of the matter equation of state is

\[
w(a) = \frac{2}{\pi d} \arctan \left( \beta \ln \left( \frac{a}{a_0} \right) \right), \quad (15)
\]

where \( a_0 \) is the value of the scale factor when \( R = 1 \), and \( \beta \) is a constant which depends on the total entropy of the gas. The larger the entropy is, the wider the Hagedorn phase as a function of \( a \), and hence the smaller the value of \( \beta \). For this equation of state, the continuity equation for string gas matter can be integrated and yields

\[
\ln \frac{\rho}{\rho_0} = - d \ln \frac{a}{a_0} - \frac{2}{\pi} \ln \left( \frac{a}{a_0} \right) \arctan \left( \beta \ln \left( \frac{a}{a_0} \right) \right) - \frac{2}{\pi} \ln \left[ 1 + \beta^2 \left( \ln \frac{a}{a_0} \right)^2 \right], \quad (16)
\]

where \( \rho_0 \) is the energy density at the string length. This result reproduces what is expected for large and small radii,

\[
\begin{align*}
\rho \text{ (large)} & \rightarrow \rho_0 \left( \frac{a}{a_0} \right)^{-d+1} \quad (17) \\
\rho \text{ (small)} & \rightarrow \rho_0 \left( \frac{a}{a_0} \right)^{-d-1}. \quad (18)
\end{align*}
\]

for pure momentum or pure winding modes, respectively.

At this point we have a system of background and matter in which both components have the same symmetries. We now turn to an exploration of solutions. Following closely [20], we make the ansatz

\[
\begin{align*}
\alpha(t) & \sim \left( \frac{t}{t_0} \right)^\alpha \quad (19) \\
\tilde{\phi}(t) & \sim - \beta \ln \left( \frac{t}{t_0} \right),
\end{align*}
\]

where \( \alpha \) and \( \beta \) are constants, and \( t_0 \) is a reference time. Inserting into the dilaton gravity equations gives the following constraints on the constants

\[
\begin{align*}
(D - 1) w \alpha + \beta &= 2 \quad (20) \\
\beta^2 + (D - 1) \alpha^2 &= 2 \beta.
\end{align*}
\]

Deep in the Hagedorn phase when \( w = 0 \) we get

\[
(\alpha, \beta) = (0, 2). \quad (21)
\]

This corresponds to a static scale factor in the string frame. Converting to the Einstein frame in which the scale factor \( \tilde{a}(t) \) is given by

\[
\tilde{a}(t) = a(t)e^{-\phi/(d-1)} \quad (22)
\]

we find

\[
\tilde{a}(t) \sim \left( \frac{t}{t_0} \right)^{2/(d-1)}. \quad (23)
\]

In the large \( a \) phase when \( w = 1/d \) we get

\[
(\alpha, \beta) = \left( \frac{2}{D}, \frac{2}{D} (D - 1) \right). \quad (24)
\]

In this case, the dilaton is constant and hence the string frame and Einstein frame scale factors are the same. As expected, the scale factor evolves as in a standard radiation dominated universe. There is a second solution of (20), but that solution is consistent only for \( p = 0 \).
When \( w = -1/d \) we have
\[
(\alpha, \beta) = \left( -\frac{2}{D}, \frac{2}{D}(D-1) \right). \tag{25}
\]
The string frame scale factor is expanding as we go backwards in time. Translating to the Einstein frame we get
\[
\dot{a}(t) \sim \left( \frac{t}{t_0} \right)^{2/(d-1)}. \tag{26}
\]
In the Einstein frame, the scale factor vanishes at \( t = 0 \) while in the string frame it blows up in this limit.

Let us track the dynamics backwards in time, beginning with a large torus \((R \gg 1)\). The energy will hence be in the momentum modes and the equation of state is that of radiation. As we go back in time, the scale factor decreases (it is the same in the two frames), the energy density increases, and eventually the temperature approaches the Hagedorn value at which point oscillatory and winding modes of the string gas get excited, leading to a transition to an equation of state with \( p = 0 \). We enter a Hagedorn phase during which the string frame scale factor is constant while the Einstein frame scale factor is decreasing. This means that the radius of the torus \( R \) is decreasing, and it soon becomes energetically preferable for the energy of the string gas to drift to the winding modes, leading to an equation of state \( w = -1/d \). In the winding phase the Einstein frame scale factor is still decreasing, which is a self-consistency check on the assumption that the energy of the string gas is mostly in the winding modes\(^3\).

We see that in the string frame, there is no curvature singularity. As the coordinate time \( t \) runs from \( t = 0 \) to \( t = \infty \), the scale factor is initially contracting, bounces in the Hagedorn phase and expands afterwards in the radiation phase, as showed schematically in Fig. 2.

Following [22], we argue that in the phase dominated by winding modes we should measure time in terms of the dual time variable
\[
t_d \equiv -\frac{t_c^2}{t} \tag{27}
\]
where \( t_c \) corresponds to the coordinate time at the center of the Hagedorn phase. In terms of \( t_d \), the solution looks like a contracting universe.

From the point of view of the Einstein frame, the scale factor vanishes at \( t = 0 \). But from the point of view of a detector made up of winding modes, the measured scale factor is proportional to \( a(t)^{-1} \). Hence, the time interval \( 0 < t < t_c \) corresponds to a contracting universe in terms of the dual position basis.

Heuristically, there are two simple reasons for introducing a dual time coordinate. Let us consider for simplicity a fixed dilaton, so that we have a radiation solution. It is clear that there is an asymmetry between large and small scale factor, since the proper time for the scale factor to go to infinity diverges, while it is finite when the scale factor decreases to zero from some finite value. However, from the point of view of T-duality we should not be able to distinguish between a large and a small universe. This is the first hint towards a more general definition of the physical clock, \( t_p \).

Another qualitative argument follows from special relativity considerations brought together with T-duality. For a large radius, rods are made out of momentum modes, and time measurements for a given physical length, \( \Delta x \), are given by
\[
|\Delta t| = |\Delta x|, \tag{28}
\]
where the speed of light has been set to unit. If the universe is composed of closed strings, in principle we could have considered measuring physical length in terms of winding modes as well, and the natural rods built out of these modes are related to the physical length by
\[
\Delta \tilde{x} \to \alpha' \frac{\Delta x}{\Delta x}, \tag{29}
\]
where \( \alpha' \) is

\(^3\) If we do not allow momentum and winding modes to decay, then, as studied in [21], we obtain solutions where the string frame scale factor oscillates about \( a_0 \).
where \( \alpha' \) is the string tension. Thus, we can rewrite (28) as,

\[
|\Delta \tilde{x}| \to \left| \frac{\alpha^2}{\Delta \tilde{t}} \right|. \tag{30}
\]

Now, if we cannot distinguish large from small, we could have started the argument using winding modes instead, so that we would write the following relation\(^4\),

\[
|\Delta \tilde{x}| = |\Delta \tilde{t}|. \tag{31}
\]

Thus, it is also natural to propose a *winding-clock* that is dual to the momentum-clock by combining the above formulae,

\[
|\Delta \tilde{t}| \to \left| \frac{\alpha^2}{\Delta t} \right|. \tag{32}
\]

Evidently, physically speaking there is only a single clock. When only winding or momentum modes are light, the existence of a unique time coordinate is already clear. Around the self-dual point, when both modes are energetically favorable, that should also be the case. Therefore, we need a prescription to reduce both time coordinates to a single physical time. We call this prescription *physical clock constraint* and it is given by the identification (27).

These ideas likely have a very natural interpretation in terms of Double Field Theory \([23]\) (see also \([24]\) for some early work). Double Field Theory is a generalization of supergravity which lives in \(2d\) spatial dimensions, with the first \(d\) dimensions corresponding to the usual \(x\) variables, and the second \(d\) dimensions to the dual spatial variables \(\tilde{x}\). In Double Field Theory there is a generalized metric which for homogeneous and isotropic cosmology and in the absence of an antisymmetric tensor field is given by

\[
ds^2 = -dt^2 + a^2(t) \delta_{ij} dx^i dx^j + a^{-2}(t) \delta^{ij} d\tilde{x}_i d\tilde{x}_j. \tag{33}
\]

The determinant of the generalized metric is one. As space shrinks in the \(x\) directions, it opens up in the \(\tilde{x}\) directions. This is sketched in Fig. 3. In work in progress \([25]\) we are exploring this connection in more detail, in particular using the \(O(D,D)\)-formalism for formalizing the introduction of a dual time, and discussing how the physical clock constraint can be seen analogously to the imposition of the section condition in DFT for the dual coordinates \([26]\).

**IV. DISCUSSION**

We have studied the equations of motion of a cosmological background containing the scale factor \(a(t)\) and the dilaton in the presence of string gas matter sources. Both the background action and the matter action are consistent with the T-duality symmetry of string theory. While we do not expect our description to be adequate in the high density phase when truly stringy effects must be considered, our analysis is an improvement over the usual effective field theory of string cosmology where the underlying background geometry is not covariant with the T-duality symmetry.

We find that the solutions are nonsingular, at least when interpreted in the context of double space-time. We conjecture that an improved description could be obtained using the tools of Double Field Theory\(^5\).
