(March 24, 2022)

The classical and quantum dynamics of the Friedmann-Robertson-Walker Universe with massless scalar and massive fermion matter field as a source is discussed in the framework of the Dirac generalized Hamiltonian formalism. The Hamiltonian reduction of this constrained system is realized for two cases of minimal and conformal coupling between gravity and matter. It is shown that in both cases for all values of curvature, \( k = 0, \pm 1 \), of maximally symmetric space there exists a time independent reduced local Hamiltonian which describes the dynamics of the cosmic scale factor. The relevance of conformal time-like Killing vector fields in FRW space-time to the existence of time independent Hamiltonian and the corresponding notion of conserved energy is discussed. The extended quantization with the Wheeler-deWitt equation is compared with the canonical quantization of unconstrained system. It is shown that quantum observables treated as expectation values of the Dirac observables properly describe the original classical theory.

I. INTRODUCTION

Cosmological models apart from the main task, to investigate the large scale structure of the Universe, are highly attractive objects with the standpoint of analysis of the conceptual problems in the theory of gravitation. By studying cosmological models instead of general spacetime we can to overcome the difficulties due to the infinite number of degrees of freedom and concentrate attention to the problems arising solely from the time reparametrization invariance; such as the construction of observables.\footnote{The problem of observables consist in the determination of the invariant characteristics of gravitational field in terms of measurable quantities\footnote{For review of the cosmological models construction with applications of the ADM method see e.g.} and is closely related to that of time evolution\footnote{To make agreement between the four-dimensional covariance and the possibility to extract from the canonical coordinates hidden variables appropriate for deparametrization theory is difficult task. To solve this problem Kuchar suggested to perform the “second parametrization” of general relativity by extending its phase space by the additional embedding variables}. In the present article we attempt a contribution to the discussion of some aspects of this problem by considering the simplest cosmological model, the Friedmann-Robertson-Walker (FRW) Universe filled in the scalar massless and massive spinor matter fields. The conventional Hamiltonian description of this model is based on the original Dirac\footnote{For review of the cosmological models construction with applications of the ADM method see e.g.} and the so-called Arnowitt-Deser-Misner (ADM)\footnote{For review of the cosmological models construction with applications of the ADM method see e.g.} formulation of general relativity. The ADM method involves the choice of certain coordinate fixing conditions (gauge), solution of the constraints and construction of the observables such as energy, momentum and angular momentum, using the asymptotically flat boundary condition for gravitational field and assuming that three-dimensional space of constant time is open\footnote{For review of the cosmological models construction with applications of the ADM method see e.g.}. However, when the closed Universe is considered to build the ADM observables from initial data for canonical variables it is impossible. Since in this case there is no boundary of the space manifold and no asymptotic region can be used to construct the corresponding integrals of motion. This leads to the conclusion that for such cosmological models neither the natural notion of time evolution nor the corresponding energy definition is possible to find\footnote{To make agreement between the four-dimensional covariance and the possibility to extract from the canonical coordinates hidden variables appropriate for deparametrization theory is difficult task. To solve this problem Kuchar suggested to perform the “second parametrization” of general relativity by extending its phase space by the additional embedding variables}. To clear up this contradiction between the existence of widely used cosmological quantities and their absence in the corresponding field theoretical formulation the FRW cosmological model will be considered in the framework of the Dirac Generalized Hamiltonian formulation\footnote{For review of the cosmological models construction with applications of the ADM method see e.g.}. The key moment of the canonical treatment is the assumption that general relativity represents “already parametrized” theory due to the principle of general covariance, so that the problem of construction of observables can be solved automatically rewriting the theory in the equivalent “deparametrized” form.\footnote{For review of the cosmological models construction with applications of the ADM method see e.g.} However, careful analysis of correctness of such deparametrized program carried out by Hajicek\footnote{For review of the cosmological models construction with applications of the ADM method see e.g.} shows that even for simple mechanical system with one quadratic Hamiltonian constraint
there are topological obstructions to its implementation analogous of the well-known “Gribov ambiguity” in gauge theories. A direct way to clarify the topological structure of such a theory lies in the finding of integral curves of the dynamical equations and the investigation their global properties. Within this motivation the present note is devoted to the realization of local deparametrization of integrable cosmological FRW models considering it as a preparation for the study the global features of reduction procedure. We will follow the method of Hamiltonian reduction to construct the observables and the corresponding dynamical equations which is well elaborated for gauge theories. This approach is based on an appropriate choice of canonical coordinates on phase space and deals without explicit introduction of any gauge-fixing functions (see e.g. [17] and references therein).

The general plan of present article is as follows. In Section II we state the FRW cosmological model with real massless scalar and massive fermion fields as sources with different type of coupling to gravity. In Section III some generic features of the Hamiltonian reduction and the construction of observables in reparametrization invariant mechanical models is discussed. The aim of Section III is to explain the method to obtain the unconstrained system from reparametrized invariant one by considering the simplest example of free relativistic particle motion. Section IV is devoted to the construction of the unconstrained systems equivalent to FRW cosmology when the homogeneous matter is presented in different forms: as massless scalar field interacting with gravity minimally and conformally, massive spinor field. Finally, in Section V we discuss the correspondence principle fulfillment for observables in quantum theories based either on Wheeler-deWitt equation or on the canonical quantization scheme of the unconstrained classical system. In Appendices we state some notations and technical details of derivations in order to simplify the reading of the main text.

II. MODEL WITH SPATIAL HOMOGENEITY AND ISOTROPY

By definition, the FRW spacetime is a four-dimensional pseudo-Riemannian manifold on which a six-dimensional Lie group $G_6$ acts as group of isometries. The group of isometries $G_6$ has a three-dimensional isotropy subgroup and three-dimensional subgroup which acts simply transitive on the one parameter ("time $t$") family of spacelike hypersurfaces $\Sigma_t$. The large group of isometries restricts both the dependence and the number of independent components of the metric tensor and leads to the so-called maximally symmetric three-dimensional space. After the choice of standard coordinates [18] one has the FRW metric

$$ds^2 = -N^2(t) dt \otimes dt + a^2(t) \gamma_{ab} dx^a \otimes dx^b,$$

where $\gamma_{ab}$ is the time independent metric of three-dimensional space

$$\gamma_{ab} dx^a \otimes dx^b = \frac{dr^2}{1-k/r_o^2} + r^2(d\theta^2 + \sin^2 \theta d\phi^2)$$

of constant curvature $(3) R(\gamma_{ij}) = -6k/r_o^2$, $k = 0, \pm 1$. The lapse function $N(t)$ and the cosmic scale factor $a(t)$ describe the remaining gravitational degrees of freedom whose classical behavior is determined by varying the standard Hilbert action. However, constructed in this way the minisuperspace model is out of interest. Simple counting of the physical degrees of freedom shows that this vacuum FRW model is empty on the classical level; only unphysical degrees of freedom propagate. Thus in order to have some nontrivial observables it is necessary to introduce the source matter fields.

1. Lagrangian for scalar field with minimal coupling to gravity

The introduction of a massless scalar field as a source of gravity results in the simplest cosmological model which has direct correspondence to the classical Friedmann model. For a massless scalar field, the two most interesting

4Apart from topological obstruction arising due to the projection onto the constraint shell it is necessary also to investigate the problems connected with the topological structure of spaces of constant curvature. The well elaborated classification of three-dimensional spacelike manifolds [14] allows to estimate the influence of topological properties on physical quantities. An interesting study of the role played by this global properties is under present consideration (see [16] and references therein).

5Below we will point out the correspondence the conventional Friedmann cosmology based on the Einstein equations supplemented by certain matter equation of state.
couplings to gravity extensively considered are the so-called minimal coupling and the conformal one. The Hilbert action for gravity minimally coupled to massless scalar field

\[ W = \int d^4x \sqrt{-g} \left[ -\frac{\kappa}{2} (\nabla^2 - \frac{k}{a^2} N_\epsilon) + \frac{1}{2} g^{\mu\nu} \partial_\mu \Phi \partial_\nu \Phi \right] \]  

(2.3)

reduces to the following

\[ W = V_3 \int dt \left[ -\frac{3}{\kappa} \left( \frac{\dot{a}^2}{N_\epsilon} - \frac{k a^2}{r_0^2} N_\epsilon \right) + \frac{a^2}{2 N_\epsilon} \dot{\Phi}^2 - \frac{3}{\kappa} \frac{d}{dt} \left( \frac{a \dot{a}}{N_\epsilon} \right) \right] , \]  

(2.4)

assuming the spatial homogeneity of the scalar field and FRW metric \((2.1)\). Here \(\kappa = 8\pi G\) and new variable \(N_\epsilon = N/a\) has been introduced. Integration over the spatial hyperplane leads to the appearance of the factor \(V_3\) — “volume” of the three-dimensional space of constant curvature.  

2. Lagrangian for a scalar field with conformal coupling to gravity

The conformally coupled scalar field is described by action

\[ W[g, \Phi] = \int d^4x \sqrt{-g} \left[ \frac{1}{2\kappa} (\nabla^2) \Phi^2 + \frac{1}{12} \left( \nabla \Phi \right)^2 + \frac{1}{2} g^{\mu\nu} \partial_\mu \Phi \partial_\nu \Phi \right] . \]  

(2.5)

Choosing the metric \((2.1)\) this leads to the action for the FRW Universe filled in by massless homogeneous scalar field \(\varphi(t) := a(t)\Phi(t)\)

\[ W[a, N_\epsilon, \varphi] = \int dt \left[ -\frac{3}{\kappa} \left( \frac{\dot{a}^2}{N_\epsilon} - \frac{k a^2}{r_0^2} N_\epsilon \right) + \frac{1}{2} \left( \frac{\varphi^2}{N_\epsilon} - \frac{k \varphi^2}{r_0^2} N_\epsilon \right) + \frac{3}{\kappa} \frac{d}{dt} \left( \frac{a \dot{a}}{N_\epsilon} \right) \right] . \]  

(2.6)

3. FRW Lagrangian with spinor matter fields

The combined system of Dirac field and FRW metric have been investigated from classical and quantum point of view by many authors. In present article we explore the model closely related to the formulation given in \([24,25]\). The starting point is the action for a massive spinor field interacting with gravity is given by

\[ W = \int d^4x \sqrt{-g} \left[ -\frac{(4)}{2\kappa} R(g) + \frac{i}{2} \left( \overline{\Psi} \gamma^\mu(x) \nabla_\mu \Psi - \nabla_\mu \overline{\Psi} \gamma^\mu(x) \Psi \right) - m \overline{\Psi} \Psi \right] , \]  

(2.7)

where the spinor field \(\Psi(x)\) (\(\overline{\Psi}\) Dirac conjugate spinor field) components are treated classically as a collection of Grassmann variables \(\Psi, \Psi_j + \Psi_j \Psi = 0\) and \(\nabla_\mu\) is the covariant derivative (see notation in Appendix \(A\)). Assuming the homogeneity of the fermion fields and after the redefinition \(\psi(t) := a^{3/2}(t)\Psi(t)\) Eq.\((2.7)\) reduces to the action of the finite dimensional system

\[ W = \int dt \left[ -3 \left( \frac{\dot{a}^2}{N_\epsilon} - \frac{k a^2}{r_0^2} N_\epsilon \right) + \frac{i}{2} (\overline{\psi} \gamma^\alpha \psi - \overline{\psi} \gamma^\alpha \psi) - aN_\epsilon \mathcal{H}_D + \frac{3}{\kappa} \frac{d}{dt} \left( \frac{a \dot{a}}{N_\epsilon} \right) \right] , \]  

(2.8)

with

\[ \mathcal{H}_D = m \overline{\psi} \psi . \]  

(2.9)

\(^6\)It is well known that essentially all types of couplings of free scalar field to the scalar curvature and its kinetic term can be reduced to minimal coupling form using rescaling of the metric and scalar field redefinition \([13]\). In 1974 based on this type of transformations Bekenstein \([20]\) proposed the method of construction solution for particular case of conformally coupled Einstein-scalar equation from solution of the minimally coupled ones (see also \([21]\)). The detailed investigation of this type solutions for FRW geometry with spatial homogeneous scalar fields can be found in \([23]\). Note also the interesting consideration of the evolution of Friedman cosmology driven by scalar fields, given in \([23]\).

\(^7\)In all formulas this factor will be omitted, in order to simplify the numerical factors.
III. REDUCTION AND OBSERVABLES IN REPARAMETRIZATION INVARIANT MECHANICAL MODELS

It is the purpose of this part to discuss the construction of observables for a system with reparametrization invariance. For our aims we shall state the ideas using a mechanical system, i.e. a system with a finite number of degrees of freedom and restrict ourselves to the case of Abelian constraints.

Let us consider a system with $2^n$-dimensional phase space $\Gamma$ whose dynamics is constrained to a certain submanifold $\Gamma_c$ describing by the functionally independent set of $m$ abelian constraints

$$\varphi_\alpha(p,q) = 0, \quad \{\varphi_\alpha(p,q), \varphi_\beta(p,q)\} = 0.$$ 

Due to the presence of constraints the Hamiltonian dynamics is described by the Poincaré-Cartan form

$$\Theta = \sum_{i=1}^{n} p_i dq_i - H_E(p,q)dt,$$

with the extended Hamiltonian $H_E(p,q)$ differing from the canonical Hamiltonian $H_C(p,q)$ by a linear combination of constraints with arbitrary multipliers $u_\alpha(t)$

$$H_E(p,q) = H_C(p,q) + u_\alpha(t)\varphi_\alpha(p,q).$$

For the case of first class constraints the functions $u_\alpha(t)$ can’t be fixed without using some additional requirements. This observation reflects the existence of the local (gauge) symmetry and the presence of coordinates in the theory whose dynamics is governed in an arbitrary way. However, according to the principle of gauge invariance, these coordinates do not affect physical quantities and thus can be treated as ignorable (gauge degrees of freedom). The question is how to identify these coordinates. If theory contains only Abelian constraints one can find these ignorable coordinates as follows. It is always possible \[20 \text{ - } 27\] to define a canonical transformation to a new set of canonical coordinates

$$q_i \mapsto Q_i = Q_i(q,p), \quad p_i \mapsto P_i = P_i(q,p),$$

so that $m$ of the new momenta ($P_1, \ldots, P_m$) become equal to the Abelian constraints

$$\overline{P}_\alpha = \varphi_\alpha(q,p).$$

In the new coordinates $(Q, \overline{P})$ and $(Q^*, P^*)$ we have the following canonical equations

$$\dot{Q}^* = \{Q^*, H_{Ph}\}, \quad \overline{P} = 0,$$

$$\dot{P}^* = \{P^*, H_{Ph}\}, \quad \overline{Q} = u(t),$$

with the physical Hamiltonian

$$H_{Ph}(P^*, Q^*) := H_C(P, Q) \bigr|_{\overline{P}_\alpha=0}.$$ 

The physical Hamiltonian $H_{Ph}$ depends only on the $(n - m)$ pairs of new gauge-invariant canonical coordinates $(Q^*, P^*)$. Moreover the form of the canonical system (3.6) expresses the explicit separation of the phase space into physical and unphysical sectors. Arbitrary functions $u(t)$ enter only into the part the equation for the ignorable coordinates $Q_\alpha$, conjugated to the momenta $\overline{P}_\alpha$. 

\[This paper deals with Abelian constraints only, but a few remarks on the general non-Abelian case may be in order. A straightforward generalization to this situation is unattainable; identification of momenta with constraints is forbidden due to the non-Abelian character of constraints. However, one can replace the non-Abelian constraints by an equivalent set of constraints forming an Abelian algebra and after this implement the above mentioned Levi-Civita transformation. For proofs of this Abelianization statement see e.g. \[11 \text{ - } 12\] and the description of iterative Abelianization conversion in \[17\].\]
Trying to apply this program to any model with reparametrization invariance we as a rule reveal that the physical Hamiltonian defined by (3.7) is zero and thus we have the dynamics of unconstrained system in the Maupertuis form

\[ \Theta_{ph} = \sum_{i=1}^{n-m} P_i^* dQ_i^* - dV, \]  

where \( dV \) is a total differential. The problem is now how to deal with the zero Hamiltonian. This situation in some sense opposite to the case known from the Hamilton-Jacobi method of integration of equations of motion. The main idea of this method is to implement on the system with Hamiltonian \( H(t, p, q) \) the canonical transformation with generating function \( S(t, q, p) \), which is the solution for the equation

\[ \frac{\partial S}{\partial t} + H(t, q, \frac{\partial S}{\partial q}) = 0. \]  

As a result the new Hamiltonian is zero and the equation of motion in the new coordinates have the simplest form

\[ \dot{Q} = 0, \quad \dot{P} = 0. \]  

After reduction we have just a system in these coordinates and the problem is to reconstruct the nonzero Hamiltonian in any other coordinates for the obtained unconstrained system. Two remarks to the picture described above may be in order. There is no difference between the local behavior in systems obtained via the reduction of reparametrization invariant theories. The specific properties, which make a difference of systems are hidden in the total differential in the Poincaré-Cartan form.

Before passing to the construction of the reduced phase space for FRW Universe it seems worth to set forth our approach to the same problem of a free relativistic particle.

### A. Digress: Reduced dynamics of free relativistic particle

For the presentation of our procedure to construct the reduced dynamical system from the degenerate system with reparametrization invariance let us start with the simplest case of free motion of a particle in Minkowski space-time writing its action in the form close to the cosmological Friedmann models (2.4), (2.6), (2.8)

\[ W[x, e] := \frac{1}{2} \int_{T_1}^{T_2} d\tau \left( \frac{x^2}{e} + em^2 \right). \]  

The independent configuration variables are particle wordline coordinates \( x_\mu(\tau) \) and the additional “vielbein” determinant \( e(\tau) \).

Invariance of the action (3.11) under the reparametrization of time \( \tau \rightarrow \tau' = f(\tau) \) spoils the uniqueness of the Cauchy problem for the corresponding equations of motion. Therefore the problem is to fix the part of the variables whose dynamics will be unique and whose initial conditions are free from any constraints. The usual way to deal with this problem consists in choosing of a gauge which tightens the parameter of evolution with the configuration variables. For example, the proper time gauge fixing \( x_0(\tau) = \tau \) leads to the instant form of the dynamics for a relativistic particle. However, let us act in spirit of the previous section and try to reproduce the results of the instant form of particle dynamics without introduction of gauge conditions.

According to the Dirac prescription the generalized Hamiltonian dynamics for the system (3.11) takes place on the phase space spanned by five canonical pairs \((e, p_e)\) and \((x_\mu, p_\mu)\) restricted by the primary constraint \( p_e = 0 \) and the secondary constraint

\[ p_\mu p^\mu - m^2 = 0. \]  

To take into account these constraints and to derive equations of motion one can consider the Poincaré-Cartan 1-form

\[ \Theta := p_e de + p_\mu dx^\mu - H_T d\tau, \]  

with the total Hamiltonian

\[ H_T := \frac{1}{2} e(p_e^2 - m^2) + \lambda(\tau)p_e. \]
The equation of motion together with both constraints follow from functional

\[ W[e, p_e; x, p; \lambda] := \int \Theta, \tag{3.15} \]

using independent variation of the canonical pairs \((e, p_e), (x, p)\) and the Lagrange multiplier \(\lambda\)

\[ \dot{x}_\mu = e p_{\mu}, \quad p_\mu = 0, \tag{3.16} \]
\[ \dot{e} = \lambda, \quad p^2 - m^2 = 0, \quad p_e = 0. \tag{3.17} \]

Let us now convince ourselves that performing certain canonical transformations one can put the equation in such form that the Lagrange multiplier function \(\lambda(\tau)\) enters only in the equation for one canonical pair. According to the general scenario described in previous section each canonical transformation

\[
\begin{pmatrix}
e \\
p_e \\
x^\mu \\
p_\mu
\end{pmatrix}
\mapsto
\begin{pmatrix}
e \\
p_e \\
X^\mu \\
\Pi_\mu
\end{pmatrix},
\]

that identifies one canonical momentum with the energy constraint (3.18), say \(\Pi_0\)

\[ \Pi_0 = \frac{1}{2}(p^2_x - m^2) \tag{3.19} \]

leads to this pattern. One possible way to complete the canonical transformations is

\[ \Pi_0 = \frac{1}{2}(p^2_x - m^2), \quad X_0 = \frac{e}{p_0}, \quad X_i = x_i - \frac{p_e}{p_0}, \tag{3.20} \]

and the inverse transformation is

\[ p_0 = \sqrt{2\Pi_0 + \Pi^2 + m^2}, \quad x_0 = X_0\sqrt{2\Pi_0 + \Pi^2 + m^2}, \quad x_i = X_i + \Pi_i x_0. \tag{3.21} \]

In terms of the new variables the total Hamiltonian is

\[ H_T = e\Pi_0 + \lambda p_e. \tag{3.22} \]

and the equations of motion separate into two parts; one for the canonical pairs \((e, p_e)\) and \(X_0, \Pi_0\), with dependence from the Lagrange multiplier \(\lambda(\tau)\)

\[ \dot{X}_0 = e, \quad \dot{e} = \lambda, \tag{3.23} \]
\[ \dot{p}_e = -\Pi_0, \quad \dot{\Pi}_0 = 0, \tag{3.24} \]

constrained by \(\Pi_0 = 0\) and the equations of motion for the variables \((X_i, \Pi_i)\)

\[ \dot{X}_i = 0 \quad \dot{\Pi}_i = 0, \tag{3.25} \]

which have a unique solution with initial values free from any restriction. One can construct the reduced Poincare-Cartan 1-form for physical unconstrained variables \(X_i, \Pi_i\) from (3.13), rewritten in terms of the new canonical variables

\[ \Theta = \Pi_0 dX^0 - \Pi_i dX_i + p_e de - (e\Pi_0 + \lambda p_e) dt + d(X_0(\Pi_0 + m^2)), \tag{3.26} \]

by considering the projection onto the constraint shell.

\[ \text{9} \]

Different possibilities to complete the canonical transformations for remaining variables will lead to another forms of dynamics, or to equivalent form but in another frame of reference.

6
Thus we have convinced ourselves that the variables $\Pi_i, X_i$ are Jacobi’s coordinates for the obtained unconstrained theory with zero Hamiltonian. Now we shall show how to reconstruct the unconstrained Hamiltonian in terms of initial variables using the generating function to new set of canonical pairs (3.20) and Hamilton-Jacobi equation. To find the unconstrained system whose Jacobi’s coordinates are $\Pi_i, X_i$ let us write down the generating function $S(\Pi, x)$ of the canonical transformation $(x, p) \rightarrow (X, \Pi)$ (3.20)

$$p = \frac{\partial S(\Pi, x)}{\partial x}, \quad X = \frac{\partial S(\Pi, x)}{\partial \Pi}.$$ (3.28)

One can easily verify from the condition

$$\Pi dX - p dx = d(X_o(\Pi_o + m^2)),$$ (3.29)

that the function

$$S(\Pi, x) = x_0 \sqrt{2\Pi_0 + \Pi^2 + m^2 - x_i \Pi_i}$$ (3.30)

generates the above canonical transformations (3.20). Restriction the generating function by the condition $\Pi_o = 0$ leads to the function

$$S^*(\Pi_i, x_i, x_0) = S(\Pi, x)|_{\Pi_o = 0} = x_0 \sqrt{\Pi^2 + m^2 - x_i \Pi_i},$$ (3.31)

which we shall now treat as generating function defined on the unconstrained phase space $(x_i, p_i)$ and depended explicitly on some parameter $x_0$, which has the meaning of evolution parameter for the obtained reduced system. To verify this, one can use the generating function $S^*(\Pi_i, x_i, x_0)$ to write down the inverse transformation for variables in the reduced Poincare-Cartan form directly on the constraint shell

$$\Theta^* = -\Pi_i dX_i + m^2 dX_o \bigg| X_i = \frac{\partial S^*}{\partial \Pi_i} = x_i = -p_i dx_i + \sqrt{p^2 + m^2} dx_o.$$ (3.32)

From this form it follows that we get the Hamiltonian system for a relativistic particle

$$\frac{dx_i}{dt} = \{x_i, h\} = \frac{2p_i}{\sqrt{p^2 + m^2}},$$ (3.33)

$$\frac{dp_i}{dt} = \{p_i, h\} = 0,$$ (3.34)

in the instant form of the dynamics with the parameter $t := x_0$ and the Hamiltonian defined from the reduced generating function

$$h = \frac{\partial S^*}{\partial x_0} = \sqrt{p^2 + m^2}.$$ (3.35)

IV. HAMILTONIAN REDUCTION OF FRW COSMOLOGICAL MODELS

A. Scalar field with minimal coupling to gravity

After performing the Legendre transformation on the Lagrangian in the action (2.4) describing the dynamics of a homogeneous scalar field with minimal coupling to FRW space time one finds that the phase space spanned by the canonical pairs $(a, p_a), (N_c, P_N)$ and $(\Phi, P_\Phi)$ is restricted by the primary constraint

$$P_N = 0$$ (4.1)

and secondary constraint
\[ C = \frac{\kappa p_a^2}{12} + \frac{3ka^2}{\kappa r_0^2} - \frac{P_p^2}{2a^2}. \]  

(4.2)

Exploiting the nondegenerate character of the metric \((a \neq 0)\) the secondary constraint (4.2) can be rewritten in the equivalent form

\[ \dot{C} = a^2 C = a^2 \left( \frac{\kappa p_a^2}{12} + \frac{3ka^2}{\kappa r_0^2} \right) - \frac{P_p^2}{2}, \]  

(4.3)

which shows the separability of the gravitational and the matter source part in constraint. To obtain the reduced Hamiltonian describing the evolution of cosmic scalar factor \(a\) one can introduce the new canonical coordinates for scalar field

\[ \Pi_\Phi := \frac{P_p^2}{2} / \Phi, \quad T_\Phi := \Phi / P_p. \]  

(4.4)

After this redefinition the corresponding Poincare-Cartan form

\[ \Theta = p_a da + \Pi_\Phi dT_\Phi - N \frac{\dot{C}}{a^2} dt + d (\Pi_\Phi T_\Phi), \]  

(4.5)

projected onto the constraint shell reduces to

\[ \Theta^* = p_a da + H(a) dT_\Phi + d (H(a) T_\Phi), \]  

(4.6)

where the reduced Hamiltonian that governs the scale factor \(a\) evolution in time \(T_\Phi\) is

\[ H(a) := a^2 \left( \frac{\kappa p_a^2}{12} + \frac{3ka^2}{\kappa r_0^2} \right). \]  

(4.7)

Note, that there is another possibility to reduce the theory. The reduced theory can be formulated in terms of a scalar field. To find the dynamics of the scalar field we perform the canonical transformation on the scale factor

\[ \Pi_a := a^2 \left( \frac{\kappa p_a^2}{12} + \frac{3ka^2}{\kappa r_0^2} \right), \]  

(4.8)

\[ T_a := \int_{a_o}^a a^2 da \left( \frac{\kappa}{3} \Pi_a - ka^4 r_o^{-2} \right)^{-1/2} \]  

(4.9)

and as a result the reduced Poincare-Cartan form in terms of scalar field variables is

\[ \Theta^* = P_\Phi d\Phi - H(P_\Phi) dT_a + d (S(a, \Pi_a) - T_a \Pi_a), \]  

(4.10)

where the reduced Hamiltonian that describes the evolution of scalar field \(\Phi\) in time \(T_a\) is

\[ H(P_\Phi) := \frac{1}{2} P_\Phi^2, \]  

(4.11)

and the function \(S(a, \Pi_a)\) is the generating function of the canonical transformation (4.8).

**B. Scalar field with conformal coupling to gravity**

In the case of a homogeneous scalar field conformally coupled to the FRW space time (2.1) the phase space spanned by the canonical pairs \((a, p_a), (N_c, P_N)\) and \((\varphi, p_\varphi)\) is restricted by the primary constraint

\[ P_N = 0, \]  

(4.12)

and secondary constraint

\[ C := \Pi_\varphi - \Pi_a, \]  

(4.13)

where
\[ \Pi_a := \frac{k^2 p_a^2}{12} + 3k a^2 \kappa r_o^2, \quad \Pi_\varphi := \frac{p_\varphi^2}{2} + \frac{k \varphi^2}{2 r_o^2}. \] (4.14)

The total Hamiltonian \( H_T := N_c C + \lambda(t) P_N \) contains the arbitrary function \( \lambda(t) \) and thus the Hamilton-Dirac equations

\[ \dot{a} = -N_c \kappa p_a / 6 \quad \dot{\varphi} = N_c p_\varphi \quad \dot{N}_c = \lambda \quad \dot{P}_N = C \quad \dot{p}_\varphi = -N_c k \varphi / r_o^2 \] (4.15)
cannot be solved in a unique way. According to the scheme described in the preceding sections to implement the Hamiltonian reduction one can search for a transformation to a new set of canonical variables in terms of which the equations of motion separate into independent parts: the physical (independent of the arbitrary function) and the unphysical one with unpredictable evolution. To achieve this let us perform the canonical transformation from \((p_a, a)\) and \((p_\varphi, \varphi)\) to the new canonical pairs such that matter part of the constraint \( \Pi_\varphi \) becomes one of the new canonical momenta

\[ \Pi_\varphi = \frac{p_\varphi^2}{2} + \frac{k \varphi^2}{2 r_o^2}. \] (4.16)

Using the generating function

\[ S(\Pi_\varphi, \varphi) := \int_a a \sqrt{2 \Pi_\varphi - \frac{k}{2 r_o^2} \varphi^2}, \] (4.17)

the corresponding canonical conjugated coordinate \( T_\varphi \) is

\[ T_\varphi = \int_a a \sqrt{2 \Pi_\varphi - \frac{k}{2 r_o^2} \varphi^2} \] (4.18)

and the reduced action reads

\[ W^* [a] = \int p_a da + \left( \frac{k}{12} p_a^2 + \frac{3k}{\kappa r_o^2} a^2 \right) dT_\varphi + d \left( S(\Pi_\varphi, \varphi) - \Pi_\varphi T_\varphi \right), \] (4.19)

It is worth mentioning that if instead of matter part the gravitational part of constraint \( \Pi_a \) will be used for the construction of the new canonical momenta then the reduced action describing the evolution of scalar field is

\[ W^* [\varphi] = \int p_\varphi d\varphi - \frac{1}{2} \left( p_\varphi^2 + \frac{k \varphi^2}{r_o^2} \right) dT_\varphi. \] (4.20)

### C. Spinor field as source field for FRW Universe

The Hamiltonian reduction of this model is achieved along the same lines as in the previous section. However, dealing with fermion fields there are some specific features due to the presence of the second class constraints.

The action (2.8) for the homogeneous spinor field in FRW Universe is degenerate and the corresponding primary constraints are

\[ C_N := p_N = 0 \]
\[ C_\psi := p_\psi + \frac{1}{2} \bar{\psi} \gamma^0 \psi = 0 \]
\[ C_{\bar{\psi}} := p_{\bar{\psi}} + \frac{1}{2} \gamma^0 \bar{\psi} = 0. \] (4.21)

Based on this action one can derive the Hubble parameter \( H^2 = \frac{1}{a^2 T_\varphi} \Pi_\varphi - \frac{k}{a^2 r_o^2} \Pi_\varphi \) and convince ourselves that it corresponds to the radiation dominated Fridmann model with the constant \( \Pi_\varphi \).
They satisfy the algebra
\[
\{C_N, C_\psi\} = 0, \quad \{C_N, C_\bar{\psi}\} = 0, \quad \{C_\psi^{(1)}, C_\bar{\psi}^{(1)}\} = -i\gamma^\alpha. \tag{4.22}
\]

According to the Dirac prescription the evolution in time is governed by the total Hamiltonian
\[
H_T = H_c + \lambda N C_N + C_\psi \lambda_\psi + \lambda_\bar{\psi} C_\bar{\psi}, \tag{4.23}
\]

with the arbitrary functions \(\lambda\) and the canonical Hamiltonian \(H_c\)
\[
H_c = N_c \left[ -\left( \frac{\kappa p_a^2}{12} + \frac{3ka^2}{\kappa r_o^2} \right) + a\mathcal{H}_D \right]. \tag{4.24}
\]

The requirement to conserve the constraints during the evolution fixes the functions \(\lambda_\psi\) and \(\lambda_\bar{\psi}\)
\[
\lambda_\psi = iN_cm_\bar{\psi}\gamma^\alpha, \quad \lambda_\bar{\psi} = iN_cm_\psi\gamma^\alpha. \tag{4.25}
\]

but leaves the function \(\lambda_N\) unspecified and leads to the existence of the secondary constraint
\[
\{C, C_\psi\} = ma_\bar{\psi}, \quad \{C, C_\bar{\psi}\} = -ma_\psi, \quad \{C, C_N\} = 0, \tag{4.27}
\]

one can verify that no additional constraints emerge. \[11\] The algebra (4.22) and (4.27) shows that the constraints represent a mixed system of first and second class constraints. In order to perform the Hamiltonian reduction we will start with rewriting the constraints into an equivalent form such that the first class constraints form the ideal of algebra and the algebra of second class constraints is canonical. This equivalent set of constraints \(\bar{C}_\psi, \bar{C}_\bar{\psi}\) is given in the Appendix B. The canonical character of the new algebra \(\{\bar{C}_\psi, \bar{C}_\bar{\psi}\} = -1\) allows to perform the canonical transformation that converts the new second class constraints \(\bar{C}_\psi, \bar{C}_\bar{\psi}\) to the pair of canonical variables
\[
\bar{\Pi}_\psi = \bar{C}_\psi, \quad \Pi_\psi = ip_\psi\gamma^\alpha + \frac{1}{2}\bar{\psi}, \quad \bar{Q}_\psi = \bar{C}_\bar{\psi}, \quad Q_\psi = m_\bar{\psi} - \frac{1}{2}\gamma^\alpha\psi. \tag{4.29}
\]

This means that the dynamics of phase space variables \(\bar{Q}_\psi, \bar{\Pi}_\psi\) is completely “frozen” and other canonical pairs change in time independently of them. In other words we can everywhere in the formulas omit this variables without destroying the dynamics of the physically relevant quantities. Turning to the reduction due to the first class constraints let us pass to the new Hamiltonian constraint \(\mathcal{C}\)
\[
\mathcal{C} := \frac{1}{a} C = \frac{1}{a} \left( \frac{\kappa p_a^2}{12} + \frac{3ka^2}{\kappa r_o^2} \right) - im\Pi_\psi\gamma^\alpha Q_\psi, \tag{4.30}
\]

assuming that the metric is nondegenerate \(a \neq 0\). In order to achieve the reduction for first class constraint we perform the canonical transformation from the \((p_a, a)\) to the new variables \((\Pi_a, Q_a)\) such that
\[
\Pi_a = \frac{1}{a} \left( \frac{\kappa p_a^2}{12} + \frac{3ka^2}{\kappa r_o^2} \right). \tag{4.31}
\]

Using the generating function \(S(a, \Pi_a)\)

\[11\] Secondary constraint \(C\) is conserved in weak sense
\[
\dot{\mathcal{C}} = iNmp_a(C_\psi\gamma^\alpha\psi + \bar{\psi}\gamma^\alpha C_\bar{\psi}) \approx 0. \tag{4.28}
\]
\[ S(a, \Pi_a) = \frac{6}{\kappa} \int_a^a da \sqrt{\frac{\kappa}{3} a \Pi_a - k a^2 r_o^{-2}}, \quad (4.32) \]

one can find the variable canonically conjugated to \( \Pi_a \)

\[ T_a = \int_a^a da \left( \frac{\kappa}{3} a \Pi_a - k a^2 r_o^{-2} \right)^{-1/2}, \quad (4.33) \]

and after projection onto the constraint shell \( C = 0, \quad \bar{C}_\psi = 0, \quad \Pi_\psi = 0, \quad \bar{C}_\phi = 0, \quad \bar{Q}_\psi = 0 \) the reduced action is

\[ W^*[Q_\psi] = \int dQ_\psi \Pi_\psi + m \Pi_\psi \gamma^\circ Q_\psi dT_a. \quad (4.34) \]

Thus we have derived the standard Dirac Hamiltonian for reduced spinor field and this matter source corresponds to the case of the dust filled Universe; the Hubble constant behaves as

\[ H^2 = \left( \frac{1}{a} \frac{da}{dT_a} \right)^2 = \frac{\kappa M_D}{3} \frac{a^3}{a^2 r_o^2} \quad (4.35) \]

with the constant \( M_D \).

We shall finish with one remark concerning the simple generalization of the above result to a more complex system. It is interesting to note that if one includes the interaction of massive spinor with the scalar massless one in the action of the following type

\[ W[g, \Phi, \Psi] = \int d^4 x \sqrt{-g} \left[ -\frac{1}{16 \pi G} (4)^R + \frac{1}{12} (4)^R \Phi^2 + \frac{1}{2} g^{\mu \nu} \partial_\mu \Phi \partial_\nu \Phi \right. \]
\[ + \frac{i}{2} (\bar{\Psi} \gamma^\mu (x) \nabla_\mu \Psi - \nabla_\mu \bar{\Psi} \gamma^\mu (x) \Psi) - m \bar{\Psi} \Psi - \mu \Phi \bar{\Psi} \Psi \], \quad (4.36) \]

then the action obtained after supposition of the FRW Universe

\[ W[a, N_c, \varphi, \psi] = \int dt \left[ -\frac{3 A^2}{\kappa N_c} + \frac{1}{2} \dot{\varphi}^2 + \frac{i}{2} (\bar{\psi} \gamma^\mu \dot{\psi} - \dot{\psi} \gamma^\mu \psi) \right. \]
\[ \left. - N_c \left( -\frac{3 k a^2}{\kappa r_o^2} + \frac{k \varphi^2}{2 r_o^2} + (ma + \mu \varphi) \bar{\psi} \psi \right) \right], \quad (4.37) \]

can be connected with the action describing the interaction of fermion field and massless scalar field. Let us consider two possible cases.

a). \( \kappa m^2 < 6 \mu^2 \). One can convince ourself that after introduction of the new scalar field \( \phi \) and the scale factor \( \alpha \)

\[ ma + \mu \varphi = \mu \phi \sqrt{1 - \frac{\kappa m^2}{6 \mu^2}} ; \quad a + m \frac{\kappa}{\mu} \varphi = A \sqrt{1 - \frac{\kappa m^2}{6 \mu^2}} \quad (4.38) \]

we get the action for the massless spinor interacting with the field \( \phi \)

\[ W[A, N_c, \phi, \psi] = \int dt \left[ -\frac{3 A^2}{\kappa N_c} + \frac{1}{2} \dot{A}^2 + \frac{i}{2} (\bar{\psi} \gamma^\mu \dot{\psi} - \dot{\psi} \gamma^\mu \psi) \right. \]
\[ \left. - N_c \left( -\frac{3 k A^2}{\kappa r_o^2} + \frac{k \varphi^2}{2 r_o^2} + \tilde{\mu} \phi \bar{\psi} \psi \right) \right], \quad (4.39) \]

and the new coupling constant

\[ \tilde{\mu} = \mu \sqrt{1 - \frac{\kappa m^2}{6 \mu^2}} \quad (4.40) \]
b). \( \kappa m^2 > 6\mu^2 \). In this case one can use another transformation,

\[
\varphi = \frac{1}{\sqrt{1 - \frac{6\mu^2}{\kappa m^2}}} \left( \phi - \frac{6\mu}{\kappa m} A \right) ; \quad a = \frac{1}{\sqrt{1 - \frac{6\mu^2}{\kappa m^2}}} \left( A - \frac{\mu}{m} \phi \right),
\]

and get the action

\[
W[A, N_c, \phi, \psi] = \int dt \left[ -\frac{3}{\kappa} \dot{A}^2 + \frac{1}{2N_c} \dot{\phi}^2 + \frac{i}{2} (\bar{\psi} \gamma^\alpha \gamma^\beta \psi - \frac{\kappa}{N_c} \phi \bar{\psi} \gamma^\alpha \gamma^\beta \gamma \psi) \right. \\
- N_c \left( -\frac{3}{\kappa} \frac{kA^2}{r_o^2} + \frac{k\phi^2}{2r_o^2} + \tilde{m}A \bar{\psi} \gamma^\alpha \gamma^\beta \gamma \psi \right),
\]

with the new mass for the fermion field \( \tilde{m} = m \sqrt{1 - \frac{6\mu^2}{\kappa m^2}} \). One can verify that these two actions are related by the field redefinition

\[
A \to \frac{i}{\kappa} \phi, \quad \phi \to \frac{i}{\kappa} A,
\]

and thus it is enough to reduce one of the actions (4.39), (4.42).

For the action (4.39) the energy constraint

\[
C = -\frac{\kappa p_a^2}{12} - \frac{3k}{\kappa} a^2 + \frac{p_\phi^2}{2} + \frac{k^2}{2r_o^2} + \tilde{m}\phi \mathcal{H}_D,
\]

again has separable contributions from the gravitational and the matter part. After introduction of the new canonical momentum

\[
\Pi_a := \frac{\kappa p_a^2}{12} - \frac{3k^2}{\kappa r_o^2} \phi^2
\]

and the corresponding conjugated coordinate \( T_a \) in the same manner as for the case of the conformal scalar field the following action for the physical scalar and spinor fields can be derived

\[
W^*[\phi, \psi] = \int dQ \Pi \psi + p_\phi d\phi - H dT,
\]

with physical Hamiltonian describing the system of interacting spinor and scalar fields

\[
H := p_\phi^2 + k\phi^2 + \tilde{m}\phi \mathcal{H}_D.
\]

V. CLASSICAL AND QUANTUM OBSERVABLES FOR FRW UNIVERSE

A. Extended quantization: Wheeler-deWitt equation

According to the Dirac prescription in the extended quantization scheme one considers the classical constraints to be the conditions on the state vector \( \Psi \)

\[
P_N \Psi = 0, \quad H_T \Psi = 0.
\]

12The standard procedure of letting \( P_N \to -i\partial_N, P_\phi \to -i\partial_\phi \) is assumed.
Quantum observable in this quantization scheme are constructed with analogy to that of the two-dimensional relativistic spin zero bosonic Klein-Gordon field as expectation value

\[ \langle O \rangle = \int d\phi (\Psi^* O \partial_\phi (\Psi) - \partial_\phi (\Psi^*) O \Psi) . \] (5.3)

However, as it has been analyzed by Kaup and Vitello [30] this conventional interpretation cannot be used without violating the correspondence principle. More precisely, it has been shown that the expectation values for the scalar fields and the cosmic scale factor do not correspond to the classical values; their evolution describe the expansion phase of Friedmann evolution, but then instead of contraction, the expectation values tunnel through the barrier and continue to expand. Below it will be demonstrated that opposite to this situation the canonical quantization of the unconstrained system obtained in the preceding part of the paper leads directly to the fulfillment of the correspondence principle.

**B. Reduced quantization: Heisenberg equation**

To analyze the correspondence principle let us consider the case of a conformal scalar field in the closed Friedmann Universe. As it has been shown the evolution of scale factor \( a \) in conformal time \( t \) is governed by the harmonic oscillator Hamiltonian which after conventional quantization reads

\[ \hat{H} = \frac{\kappa}{12} \hat{p}^2 + \frac{3}{\kappa r_o^2} \hat{a}^2 . \] (5.4)

Assuming the quantum state in the form

\[ \Psi = \frac{1}{(\alpha^2 \pi)^{1/4}} \exp \left[ -\frac{i}{\hbar} p_o a - \frac{(a - a_o)^2}{2\alpha^2} \right] \] (5.5)

where \( a_o \) and \( p_o \) are the mean values of the coordinate and the momentum respectively (real parameter \( \alpha \) characterizes the mean square deviation of \( a \)) and using the solution of Heisenberg equations for the operators \( \hat{a}(t) \) and \( \hat{p}(t) \)

\[ \hat{a}(t) = \hat{a}(0) \cos \frac{t}{r_o} - \frac{\kappa r_o}{6} \hat{p}(0) \sin \frac{t}{r_o} , \] (5.6)

\[ \hat{p}(t) = \frac{6}{\kappa r_o} \hat{a}(0) \sin \frac{t}{r_o} + \hat{p}(0) \cos \frac{t}{r_o} , \] (5.7)

one can find the time dependence of the mean values of \( \hat{a}(t) \) and \( \hat{p}(t) \),

\[ a(t) = \int_{-\infty}^{+\infty} \Psi^* \hat{a}(t) \Psi da = a_o \cos \frac{t}{r_o} - \frac{\kappa r_o}{6} p_o \sin \frac{t}{r_o} , \] (5.8)

\[ p(t) = \int_{-\infty}^{+\infty} \Psi^* \hat{p}(t) \Psi da = \frac{6}{\kappa r_o} a_o \sin \frac{t}{r_o} + p_o \cos \frac{t}{r_o} . \] (5.9)

This means that we have the correspondence with the classical formulae

\[ a(t) = r_o \sqrt{\frac{3}{\kappa |H|}} \sin \left( \frac{Q - T_c}{r_o} \right) \] (5.10)

\[ p(t) = \sqrt{\frac{12}{\kappa |H|}} \cos \left( \frac{Q - T_c}{r_o} \right) \] (5.11)

when constants are taken as

\[ a_o = r_o \sqrt{\frac{\kappa}{3 |H|}} \sin \frac{Q}{r_o} , \quad p_o = \sqrt{\frac{12}{\kappa |H|}} \cos \frac{Q}{r_o} . \] (5.12)

At the end we note that there is no wave packet diffusion when the mean square deviation
\[(\Delta a(t))^{2} = \frac{\alpha^{2}}{2} \left( \cos^{2} \frac{t}{r_{\sigma}} + \left( \frac{\kappa r_{\sigma}}{6} \right)^{2} \frac{h^{2}}{\alpha^{4}} \sin^{2} \frac{t}{r_{\sigma}} \right) \quad (5.13)\]

is time independent. This holds for the special value of \(\alpha\)
\[\alpha^{2} = \frac{h^{2}}{6} \kappa r_{\sigma}. \quad (5.14)\]

VI. CONCLUDING REMARKS

In the present paper the method of Hamiltonian reduction for reparametrization invariant mechanical systems have been elaborated. This approach is based on the choice of adapted coordinates using the generating function of the canonical transformation that is a solution of the corresponding Hamilton – Jacobi equation. We have derived the reduced Hamiltonians for the Friedmann cosmological models with homogeneous scalar and spinor field matter sources and find the corresponding observable time. The obtained reduced Hamiltonians have two attractive peculiarities:

i. They are the generators of evolution with respect to observable time;

ii. They are conserved quantities which can be treated as the energy of the reduced systems.

Furthermore, the representation for the Hubble parameter and the red shift is founded in terms of the Dirac observables in the frame of the generalized Hamiltonian dynamics and correspondence between field Friedmann models and perfect fluid Friedmann models with different equations of state has been established.

The comparison of extended quantization with the Wheeler-deWitt equation and the canonical quantization of unconstrained system shows the conceptual advantage of later. In reduced system with the Schrödinger type equation instead of the to the Wheeler-deWitt equation the wave function is normalizable and has clear standard quantum mechanical interpretation. It is shown that quantum observables treated as expectation values of the Dirac observables properly describe the original classical theory.

It is in order here to make a remark concerning the relation to the conventional gauge-fixing method. Certainly, the results derived in the present note by reduction without introduction of gauge functions can be reproduced by the gauge fixing method. However, from our derivation it is clear that due to the complicated relations between the initial variables and the observable time the gauge functions depend on the initial variables in a complex way which is difficult to guess.

Finally we would like to point out the possibility to exploit the suggested approach. The method elaborated in the present article can be used in the description of the other cosmological models, like Bianchi cosmologies, with different type of global symmetries. But the applicability of obtained results to a general problem of observables meets with the several difficulties. Nevertheless, we hope that in combination with other refined methods our approach will help to extend our understanding of the puzzle of the observables in theory of gravity.

VII. ACKNOWLEDGMENTS

We would like to thank S.Gogilidze, D.Mladenov, H.-P.Pavel and V.Pervushin for helpful and critical discussions. This work was supported in part by the Russian Foundation of Basic Research, Grant No 99-01-00101.

APPENDIX A: DIRAC EQUATION IN FRW SPACE TIME

To describe a spinor field on a Rimanian manifold the vierbein fields \(h^{\mu}_{\nu}(x)\) \(\mu, \nu, a, b = 0, 1, 2, 3\)
\[ds^{2} = g_{\mu \nu}dx^{\mu}dx^{\nu} = \eta_{ab}(h^{a}_{\mu}dx^{\mu})(h^{b}_{\nu}dx^{\nu}) ; \quad \eta_{ab} := (+ - - -),\]
and the Dirac \(\gamma\)-matrices with a specific dependence on space time coordinates are introduced
\[\gamma^{\mu}(x) = h^{\mu}_{a}(x)\gamma^{a}.\]

\[\text{The conservation of the conformal matter Hamiltonian with respect to conformal time translations follows from conformal symmetry of the Robertson – Walker space-time.}\]
The following relations between the vierbein fields and the metric tensor \( g_{\mu \nu} \) hold

\[
\begin{align*}
  h^{\mu}_{a} h_{\mu} &= \eta_{ab} ; \\
  h^{\mu}_{a} h_{\mu a} &= g_{\mu \nu} ; \\
  h^{\mu}_{a} h^{\nu}_{b} &= \delta_{b}^{\nu} ; \\
  h^{\mu}_{a} h_{\mu} &= \delta_{a}^{\mu} ; \\
  h_{a \mu} &= \eta_{ab} h^b_{\mu} = g_{\mu \nu} h_{\nu a} .
\end{align*}
\] 

(A1)

The Dirac equation for spinors in curved space time reads

\[
(i \gamma^\mu (x) \nabla_\mu - m) \Psi(x) = 0 ,
\]

(A2)

with the covariant derivative

\[
\nabla_\mu \Psi(x) = [\partial_\mu + \frac{1}{4} C_{abc} \gamma^b h^c_\mu] \Psi(x) ,
\]

(A3)

where Ricci coefficients

\[
C_{abc} = (\nabla_\mu h^c_\nu) h_{b\nu} h^a_\mu ; \\
\nabla_\mu h^a_\nu = (\Gamma^\nu_{\mu \lambda} - h^c_\nu \partial_\mu h^b_\lambda) h^a_\lambda,
\]

(A4)

are introduced. For the specific case of the Robertson – Walker metric,

\[
ds^2 = a^2(t) ds^2 = a^2(t) \left[ (N(t) dt)^2 - \left( 1 + \frac{kr^2}{4r_o^2} \right)^{-2} (dr^2 + r^2 (d\xi^2 + \sin^2 \xi d\zeta^2)) \right]
\]

(A5)

the following vierbein fields

\[
\begin{align*}
  h^{\mu}_{o} &= aN \\
  h^{\mu}_{1} &= a \left( 1 + \frac{kr^2}{4r_o^2} \right)^{-1} \\
  h^{\mu}_{2} &= ar \left( 1 + \frac{kr^2}{4r_o^2} \right)^{-1} \\
  h^{\mu}_{3} &= ar \sin \zeta \left( 1 + \frac{kr^2}{4r_o^2} \right)^{-1}
\end{align*}
\]

(A6)

are used in the main text. Here the vierbein indices are underlined. The Dirac equation then looks

\[
\frac{i}{a} \left[ \begin{array}{c}
\gamma^0 \frac{1}{N} \partial_t + \gamma^1 \left( 1 + \frac{kr^2}{4r_o^2} \right) \frac{\partial}{\partial r} + \gamma^2 \frac{1 + \frac{kr^2}{4r^2}}{r} \frac{\partial}{\partial \zeta} + \gamma^3 \frac{1 + \frac{kr^2}{4r_o^2}}{r \sin \zeta} \frac{\partial}{\partial \xi}
\end{array} \right] \Psi(x) - m \Psi(x) = 0 .
\]

(A7)

To maintain the space homogeneity of the Friedmann Universe we suppose that the spinor field is only time dependent. In the main text the FRW Universe with the spinor matter source is formulated in terms of the fermion variable \( \psi \)

\[
\psi(t) = a^{3/2}(t) \Psi(t).
\]

(A8)

**APPENDIX B: SEPARATION OF FIRST AND SECOND CLASS CONSTRAINTS IN MODEL WITH SPINOR FIELD**

The set of constraints \( C_A = (C_\psi, C_{\bar{\psi}}, C) \) represent a mixed system of first and second class constraints; the rank of the Poisson matrix \( \mathcal{M} = \{ C_A, C_B \} \) is equal to two. The explicit form of the Poisson matrix is

\[
\mathcal{M} = \begin{pmatrix} \triangle & K \\ -K^T & 0 \end{pmatrix},
\]

where and \( \triangle \) and \( K \) denote

\[
\triangle = \begin{pmatrix} 0 & -i\gamma^0 \\ -i\gamma^0 & 0 \end{pmatrix} \quad \quad K = \begin{pmatrix} -ma\bar{\psi} \\ ma\psi \end{pmatrix}.
\]

15
In order to perform the reduction procedure it is useful to separate first and second class constraints. One can easily verify that applying the similarity transformation

$$T = \begin{pmatrix} 1 & 0 \\ K T \Delta & 1 \end{pmatrix}, \quad \text{Sdet}T \neq 0$$

to the constraints $C_A$

$$\tilde{C} = T \cdot C = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ ima \gamma^o \psi & -i am \bar{\psi} \gamma^o \\ 1 \end{pmatrix} \cdot \begin{pmatrix} C_v \\ C_{\bar{\psi}} \\ C \end{pmatrix}$$

we achieve the separation of the constraints on the surface defined by the second class constraints

$$\{\tilde{C}, \tilde{C}_v\} = ima \tilde{C}_v \gamma^o \quad \{\tilde{C}, \tilde{C}_{\bar{\psi}}\} = -i ma \gamma^o \tilde{C}_{\bar{\psi}}.$$  

To have this separation on the whole phase space one can pass to the new set of constraints

$$\tilde{C} = \tilde{C} + ma \tilde{C}_v \tilde{C}_{\bar{\psi}}$$

$$= \Pi + ma \left( p_\psi p_{\bar{\psi}} - i 2 \left[ p_\psi \gamma^o \psi + \bar{\psi} \gamma^o p_{\bar{\psi}} \right] \right) - \frac{1}{4} a \mathcal{H}, \quad (B1)$$

$$\tilde{C}_v = -i \tilde{C}_v \gamma^o = -i p_\psi \gamma^o + \frac{1}{2} \bar{\psi}, \quad (B2)$$

$$\tilde{C}_{\bar{\psi}} = \tilde{C}_{\bar{\psi}} = p_{\bar{\psi}} + \frac{i}{2} \gamma^o \psi. \quad (B3)$$

In this new set $\tilde{C}$ belongs to the ideal of the algebra of constraints

$$\{\tilde{C}, \tilde{C}_v\} = \{\tilde{C}, \tilde{C}_{\bar{\psi}}\} = 0, \quad (B4)$$

and second class constraints $\tilde{C}_v, \tilde{C}_{\bar{\psi}}$ obey the canonical algebra

$$\{\tilde{C}_v, \tilde{C}_{\bar{\psi}}\} = -1. \quad (B5)$$

**APPENDIX C: REDUCED HAMILTONIAN AS CONSERVED QUANTITY FROM CONFORMAL SYMMETRY**

In this Appendix we discuss the existence of time independent reduced Hamiltonians from the geometrical standpoint. The Friedmann – Robertson – Walker space-time is conformally flat

$$ds_{FRW}^2 = A^2(x)^2 \cdot ds_{Minkowski}^2. \quad (C1)$$

In the flat Friedmann Universe the conformal factor $A(x)$ is simple scale factor $a(T_c)$ and it is easy to verify that the conformal time translation is a conformal symmetry

$$\mathcal{L}_{\partial_T} g_{\mu \nu} = \mathcal{L}_{\partial_T} (a^2(T_c) \eta_{\mu \nu}) = \eta_{\mu \nu} \partial_T a^2(T_c) = g_{\mu \nu} \frac{\dot{a}}{a}. \quad (C2)$$

It is well-known that if space time possesses the conformal Killing vector and matter energy-momentum tensor is traceless, then one can construct the conserved quantity as follows. Considering the covariant derivative of contraction of the stress tensor and the conformal Killing vector

$$\nabla_\mu P^\mu = \nabla_\mu (\xi_\nu T^{\mu \nu}) = \xi_\nu \nabla_\mu T^{\mu \nu} + T^{\mu \nu} \frac{1}{2} (\nabla_\mu \xi_\nu + \nabla_\nu \xi_\mu)$$

$$= \xi_\nu \nabla_\mu T^{\mu \nu} + \frac{1}{2} T^{\mu \nu} \nabla_\mu \xi_\nu,$$

and assuming the covariant conservation of the traceless matter energy-momentum tensor

$$\dot{\mathcal{H}} = \mathcal{L}(\dot{a}, a) \mathcal{H} = 0 = \frac{\dot{a}}{a} \mathcal{H}.$$
\[ \nabla_{\mu} T^{\mu\nu} = 0, \quad T^\mu_\mu = 0, \]  

we have the conservation law for four-vector \( P^\mu \) in the covariant differential form

\[ \nabla_{\mu} P^\mu = 0. \]  

To get the global conserved quantity one can integrate this equality over the whole space-time and use Gauss theorem

\[ \int_V d^4x \sqrt{-g} \nabla_{\mu} (\xi_\nu T^{\mu\nu}) = \int_V d^4x \frac{\partial}{\partial x^\mu} (\sqrt{-g} \xi_\nu T^{\mu\nu}) \]

\[ = \int_{T_c} (\xi_\nu T^{\mu\nu} \sqrt{-g} d^3x - \int_{T_c} (\xi_\nu T^{\mu\nu} \sqrt{-g} d^3x, \]

where in the last line we specify the Killing vector corresponding to the conformal translation in Robertson – Walker space-time. For the conformal scalar field with Lagrangian

\[ L = \sqrt{-g} \left( \frac{1}{2} g^{\mu\nu} \partial_\mu \Phi \partial_\nu \Phi + \frac{1}{12} (\mathcal{R} \Phi^2) \right), \]

the canonical stress tensor

\[ T^{\mu\nu}_C = \partial_\mu \Phi \partial_\nu \Phi - g_{\mu\nu} \frac{1}{\sqrt{-g}} L \]

has nonzero trace \( T^{\mu\mu}_C \neq 0 \). However, according to [31], one can pass to the improved tensor

\[ T_{\mu\nu} = T^{\mu\nu}_C - \frac{1}{6} \left[ (\mathcal{R}^{\mu\nu} + \partial_\mu \partial_\nu - g_{\mu\nu} \partial^\rho \partial_\rho) \Phi^2 \right], \]

which is traceless \( T_{\mu}^\mu = 0 \). Thus for a conformal time Killing vector in adapted coordinates \( \xi_{T_c} = (1, 0, 0, 0) \) and for homogeneous scalar field \( \varphi(T_c) = a(T_c) \Phi(T_c) \) from eq. (C5) it follows that

\[ H = \int_{T_c} (\xi_\nu T^{\mu\nu} \sqrt{-g} d^3x - \int_{T_c} (\xi_\nu T^{\mu\nu} \sqrt{-g} d^3x, \]

is conserved charge that coincides with the reduced Hamiltonian derived in the main text.
