**Keywords:** *Chrysophyllum albidium*; Root extract; Sperm motility; Sperm morphology; Fertility; Epididymis.

**Abstract.** This study evaluated the effects of administration of aqueous root extracts of *Chrysophyllum albidum* on sperm characteristics and histology of the epididymis of experimental rats. Forty-five adult male Wistar rats were randomized into 3 groups of 15 rats each. Each group was further randomized into 3 subgroups of 5 rats each, according to the dose and duration of extract administration. Administration of the extract for 8 weeks resulted in significant (P < 0.05) decreases in the number of progressively motile sperm cells of rats in subgroup B3 (75.00 ± 0.00 %) and C3 (75.00 ± 0.00 %) as compared with the control subgroup A3 (80.00 ± 0.00 %). Also, there were significant (p < 0.05) decreases in the number of morphologically normal sperm cells of rats in test subgroups B3 treated with low dose and C3 treated with high dose. However, there were no significant histological changes in the epididymis of the experimental rats in all the treated groups, at different doses and duration. Administration of aqueous root extract of *Chrysophyllum albidum* at varying doses and time duration negatively affects sperm motility and morphology which may compromise the fertility of the experimental rats.

**Introduction**

In Africa, thousands of plants have been used and are still been used for medicinal purposes. The use of these medicinal plants for therapeutic purposes transcends all cultures and traditions. It is a vital approach that is easily accessible to the populace and at little or no cost. An important aspect of reproductive health is the regulation of fertility, i.e. contraception and management of infertility [1]. Over the years, there has been an increase in the search for male contraceptives of natural origin with the lowest possible side effect [2]. Although there are many contraceptive agents with varying side effects, several medicinal plants have been shown to exhibit male contraceptive properties by either suppressing spermatogenesis or by spermicidal action [3].

Medicinal plants are herbal remedies for the treatment and management of different ailments [4]. *Chrysophyllum albidum*, also known as White Star Apple or African Star Apple, is a popular medicinal plant which belongs to the family *Sapotaceae*. Phytochemical analyses show that *Chrysophyllum albidum* contains alkaloids, tannin, saponin, phenol and flavonoid [5]. The different parts of the plants; leaves, bark, seeds and fruits, has its own medicinal value. The leaf is used as a skin moisturizer and for the treatment of skin eruption, stomach ache and diarrhoea [6]. The bark decoction is often used in the treatment of diseases such as yellow fever and malaria [7]. Onyeka et al. [8] reported that the root bark has anti-fertility effects while Adewoye et al. [9] reported that the stem bark has antimicrobial effects. The seed cotyledons are used as ointments in the treatment of vaginal and skin infections [10]. However, the extensive, long-term usage of herbal products without proper monitoring has brought about a number of health related problems like infertility, a
common problem affecting most couples all over the world [11]. Thus, this study was carried out to evaluate the possible dose and duration-dependent effects of aqueous *Chrysophyllum albidum* roots extract on sperm characteristics and epididymis of adult male Wister rats.

**Materials and Methods**

**Plant material and extract preparation**

The root bark of *Chrysophyllum albidum* was obtained from a local garden in Benin City and authenticated by a plant taxonomist in the Department of Plant Biology and Biotechnology, University of Benin. The root bark was properly washed, air dried at room temperature for few days and oven dried, after which it was pulverized into fine powder using a mechanical grinder. The powder was weighed and about 800g of it was macerated with 1.5 litres of distilled water for 24 hours. The mixture was stirred and shaken continuously using a magnetic stirrer and afterwards filtered using Whatman No 1 filter paper. The filtrate was concentrated using a rotary evaporator.

**Experimental animals**

Forty-five (45) adult male Wistar rats weighing between 200g and 250g were used for this study. The experimental rats were bred in the animal holdings of the Department of Anatomy, School of Basic Medical Sciences, University of Benin, Benin City. The rats were allowed to acclimatize to the animal house for two weeks with free access to feed (growers mash from Bendel Feed Flour Mill Ltd) and water. They were maintained on a 12 hour light and dark cycle and cared for in accordance with the guidelines of the Research Ethics Committee of the College of Medical Sciences, University of Benin, Benin City.

**Experimental design**

The experimental animals were randomized into 3 groups of 15 rats each and treated as follows:

**Group A**: The rats in this group served as control and were given normal diet and distilled water.

**Group B**: Aqueous extract of *Chrysophyllum albidum* was administered orally at 250mg/kg (low dose) to the rats in this group.

**Group C**: Aqueous extract of *Chrysophyllum albidum* was administered orally at 500mg/kg (high) to the rats in this group.

Each group was further subdivided (randomized) into 3 subgroups, with 5 rats each, according to the duration of administration of the extract as follows;

| Grouping of experimental rats according to dose and duration of administration |
|-------------------------------|----------------|-----------------|----------------|
| **Main groups** | **Control** | **Low Dose** | **High Dose** |
| **Sub groups** | **A** | **B** | **C** |
| **A1** | **A2** | **A3** | **B1** | **B2** | **B3** | **C1** | **C2** | **C3** |
| 4 wks | 6 wks | 8 wks | 4 wks | 6 wks | 8 wks | 4 wks | 6 wks | 8 wks |

**Body and organ weight measurements**

The body weights of the rats were taken weekly while their organ weights were taken at the end of the experiment (after sacrifice) using a Top loader weighing balance. The differences in body weights were determined.

**Determination of LD$_{50}$**

The LD$_{50}$ of *Chrysophyllum albidum* root bark as determined by Adewoye et al. [12] is 1850mg/kg body weight.
Extract administration and duration

The extract was administered orally and daily using an orogastric tube. Subgroups A1, B1 and C1 were given extract for 4 weeks (28 days), subgroups A2, B2, and C2 for 6 weeks (42 days) while A3, B3 and C3 were given extract for 8 weeks (56 days).

Sacrifice of animals

At the end of each experimental period (i.e. at week 4, week 6 and week 8), a transverse incision was made through the ventral wall of the abdomen of each rat under slight chloroform anaesthesia. The epididymis were excised and fixed in Bouin’s fluid in readiness for routine histological procedure. Sperm cells were collected from the vas deferens of the sacrificed rats. Sperm analysis were conducted immediately the sperm cells were excised from the vas deferens.

Sperm analysis

Sperm cells were collected from the epididymis during the sacrifice by ligating the extremities of the vas deferens to a length of about 36 nm and 6 μl normal saline was added to the ligitated extremities. The ligated extremities of the vas deferens were placed on a Petri dish and teased to allow the sperm cells diffuse. The section was viewed under the microscope for sperm motility. The results were evaluated using two variables as stated below:

1) Progressive (or qualitative) motility, usually expressed in terms of mean Progressive motility score - Progressive Motility (PM), Non Progressive Motility (NPM), Immotile (IM).
2) Percentage of motile spermatozoa.

Vitality test was carried out to evaluated living and dead spermatozoa. This was done with a supra-vital stain (eosin Y).

Sperm Morphology was evaluated by making a smear of sperm cell on a grease free slide and allowing it to air dry. The sample was stained using the Bryan-Leishman technique [20] for 30 mins. The smear was rinsed with distilled water, bloated and finally air dried. It was then viewed under oil immersion objective lens. The scores or results were recorded as a percentage of normal and abnormal sperm cells. Normal sperm shows a normal sperm characteristic of head, axoneme, middle piece and a tail. Abnormal sperm cells were characterized by large heads; headless, tailless, bulgy mid-piece curved tail and joined head.

Histological procedure

The tissues were fixed in Bouin’s fluid for less than 24 hours. The tissues were then processed via paraffin wax embed method of Drury and Wallington [13] and Scheehan and Brapchak [14].

Haematoxylin and eosin staining method

Staining of the tissues was done using H & E dyes (Haematoxylin and Eosin dyes).

Photomicrography

The sections were examined under a Leica DM750 research microscope with a digital camera Leica ICC50 attached. Digital photomicrographs of the tissues section were taken at various magnifications.

Statistical analysis

The data generated were analyzed using descriptive and inferential statistics. Data were presented as Mean ± Standard Error of Means (S.E.M). Significance difference of means was determined using one-way analysis of variance (ANOVA) at 95% confidence interval. Least Square Difference (LSD) and post-hoc tests were carried out for all groups. All statistical analysis was carried out using Statistical Package for Social Sciences (SPSS) (version 17) manufactured by International Business Machine Corporation (IBM) in Armonk, New York.
Results

The effects of administration of aqueous root extracts of *Chrysophyllum albidum* on the body weights, organ weights, sperm characteristics and histology of the epididymis of the experimental rats are as shown below;

**Effect on body weight**

![Figure 1](image1.png)

**Figure 1.** Effect of aqueous root extract of *Chrysophyllum albidum* on the initial and final body weight of the experimental rats for 4 Weeks

![Figure 2](image2.png)

**Figure 2.** Effect of aqueous root extract of *Chrysophyllum albidum* on the initial and final body weight of the experimental rats for 6 Weeks
Figure 3. Effect of aqueous root extract of *Chrysophyllum albidum* on the initial and final body weight of the experimental rats for 8 Weeks

At the 4th week (day 28), 6th week (day 42) and 8th week (day 56) of the experiment (Fig 1, 2 & 3), animals in the three groups showed both decrease and increase in body weight at varying periods of the experiment. There was no significant difference (p > 0.05) between the initial and final body weight of the treated group as compared to the control group.

**Effect on organ weight**

Figure 4. Effect of aqueous root extract of *Chrysophyllum albidum* on the relative organ weight of the right epididymis of the experimental rats
There was no significant difference (p > 0.05) in changes in the relative organ (right and left epididymis) weight between the treated groups and the control group, at the 4th, 6th and 8th week of the experiment (Fig. 4 & 5).

### Effect on total sperm count

At the 4th week of extract administration (Fig. 6), there was no significant difference (p > 0.05) between the total sperm count of the rats in the control group A1 (34.00 ± 4.00 x 10^6 cells/ml) and those of the treated groups (B1: 36.50 ± 1.5 x 10^6 cells/ml and C1: 35.50 ± 3.50 x 10^6 cells/ml).

At the 6th week (Fig. 6), the total sperm count of rats in the control group A2 (35.50 ± 4.00 x 10^6 cells/ml) was not significantly different (p > 0.05) from those in the treated groups (B2: 33.50 ± 0.5 x 10^6 cells/ml and C2: 34.50 ± 1.5 x 10^6 cells/ml).
At the 8th week of administration (Fig. 6), the total sperm count of rats in the control group A3 (34.00 ± 2.00 x 10^6 cells/ml) was not significantly different (p > 0.05) from those in the treated groups (B3: 32.00 ± 1.0 x 10^6 cells/ml and C3: 30.00 ± 2.00 x 10^6 cells/ml).

**Effect on sperm motility**

![Sperm Motility Graph](image)

**Figure 7.** Effect of aqueous root extract of *Chrysophyllum albidium* on Sperm Motility (Progressive, Non-progressive and immotile) of the experimental Rats for 4 weeks, 6weeks and 8 weeks. Bars represent Mean ± SEM. Superscript * indicate means with significant (P<0.05) difference compared to group A (Control)

At the 4th week (day 28) of extract administration, there was no significant difference (p > 0.05) between the number of progressively motile sperm cells of rats in subgroup B1 treated with low dose (80.00 ± 0.00 %) and that of the control rats A1 (80.00 ± 0.00 %). However, there was a significant (P < 0.05) decrease in the number of progressively motile sperm cells in sub group C1 treated with high dose (75.00 ± 5.00 %) than the control A1 (80.00 ± 0.00 %). Also, there were significant (P < 0.05) decreases in the percentages of non-progressively motile sperm of rats in subgroup B1 (10.00 ± 0.00 %) and subgroup C1 (10.00 ± 0.00 %) than those of rats in the control group A1 (15.00 ± 0.00 %). The administration of the extract for 4 weeks caused significant (P < 0.05) increases in the percentages of immotile sperm of the experimental rats in subgroups B1 and C1 (10.00 ± 5.00 % and 15.00 ± 0.00 % respectively) than those of the control rats A1 (5.00 ± 0.00 %) (Fig. 7).

At week 6 (day 42) of the experiment, administration of the extract did not result in any significant (P>0.05) difference in the number of progressively motile sperm cells of rats in subgroup B2 treated with low dose of the extract (80.00 ± 0.00 %) as compared with the control A2 (80.00 ± 0.00 %). Administration of the extract resulted in a significant (p < 0.05) decrease in the number of progressively motile sperm cells in sub group C2 treated with high dose (75.00 ± 5.00 %) as compared to the control A2 (80.00 ± 0.00 %). At the 6th week of extract administration, the percentage of non-progressively motile sperm cells in subgroup B2 (10.00 ± 0.00 %) was not significantly different (P > 0.05) from that of the control A2 (10.00 ± 0.00 %) while that of subgroup C2 (15.00 ± 5.00 %) was significantly (P < 0.05) higher than that of the control group A2 (10.00 ± 0.00 %). There was no significant difference (P > 0.05) in the percentages of immotile sperm cells of rats in subgroup B2 and C2 (10.00 ± 5.00 % and
10.00 ± 0.00 % respectively) compared with that of the control (10.00 ± 0.00 %) after 6 weeks of extract administration (Fig. 7).

In Fig. 7, administration of extract of *Chrysophyllum albidium* for 8 weeks resulted in significant (P < 0.05) decreases in the number of progressively motile sperm cells of rats in subgroup B3 (75.00 ± 0.00 %) and C3 (75.00 ± 0.00 %) as compared with the control group A3 (80.00 ± 0.00 %). Also, the administration of the extract resulted in a significant (P < 0.05) increase in the percentage of non-progressively motile sperm cells in subgroup B3 (15.00 ± 5.00 %) and no significant difference (P > 0.05) in subgroup C3 (10.00 ± 0.00 %). Although, as compared with control group A3 (10.00 ± 0.00 %), there was no significant difference (P > 0.05) in the percentage of immotile sperm cells of rats in subgroup B3 (10.00 ± 0.00 %), there was a significant (P < 0.05) increase in subgroup C3 treated with high dose (15.00 ± 5.00 %).

**Effect on sperm morphology**

![Sperm Morphology](image)

**Figure 8.** Effect of aqueous root extract of *Chrysophyllum albidium* on the Sperm Morphology of the experimental Rats at the 4th week (day 28), 6th week (day 42) and 8th week (day 56) of the experiment. Bars represent Mean ± SEM. Superscript * indicate means with significant (P<0.05) difference compared to group A

In Fig. 8, after administration of aqueous root extract of *Chrysophyllum albidium* for 4 weeks, there was no significant difference (P > 0.05) in the number of morphologically normal sperm cells of test rats in subgroups B1 (36.50 ± 1.5 x 106 cells/ml; 80.00 ± 0.00 %) and C1 35.50 ± 3.50 x 106 cells/ml; 80.00 ± 0.00 %) compared to those of the control subgroup A1 (34.00 ± 4.00 x 106 cells/ml; 85.00 ± 5.00 %). Also, there was no significant difference (P > 0.05) in the number of morphologically abnormal sperm cells of test rats in subgroups B1 (36.50 ± 1.5 x 106 cells/ml; 20.00 ± 0.00 %) and C1 (35.50 ± 3.50 x 106 cells/ml; 20.00 ± 0.00 %) compared to those in control subgroup A1 (34.00 ± 4.00 x 106 cells/ml; 15.00 ± 5.00 %).

Administration of aqueous root extract of *Chrysophyllum albidium* for 6 weeks (Fig. 8) resulted in significant (P < 0.05) decreases in number of morphologically normal sperm cells of rats in subgroup B2 treated with low dose of the extract (36.50 ± 1.5 x 106 cells/ml; 75.00 ± 5.00 %) and
subgroup C2 treated with high dose of the extract (34.50 ± 1.5 x 10^6 cells/ml; 70.00±0.00 %) as compared to the control subgroup A2 (35.50±4.00 x 10^6 cells/ml; 85.00±5.00 %). Also, it resulted in significant (P < 0.05) increases in the number of morphologically abnormal sperm cells of rats in test subgroups B2 (36.50±1.5 x 10^6cells/ml; 25.00±0.00 %) and C2 (34.50±1.5 x 10^6 cells/ml; 30.00±0.00 %) as compared to the control subgroup A2 (35.50±4.00 x 10^6 cells/ml; 15.00±5.00 %).

At the 8th week of experiment, administration of the extract caused significant (p < 0.05) decreases in the number of morphologically normal sperm cells of rats in test subgroups B3 treated with low dose (32.00±1.0 x 10^6 cells/ml; 70.00 ± 0.00 %) and C3 treated with high dose (30.00 ± 2.00 x 10^6 cells/ml; 70.00 ± 0.00 %) as compared to the control subgroup A3 (34.00 ± 2.00 x 10^6 cells/ml; 90.00 ± 0.00 %). Also, there were significant (P < 0.05) decreases in the number of morphologically abnormal sperm cells of rats in the test subgroups B3 (32.00±1.0 x 10^6 cells/ml; 30.00±0.00 %) and C3 (30.00±2.00 x 10^6 cells/ml; 30.00±0.00 %) as compared to rats in the control subgroup A3 (34.00±2.00 x 10^6 cells/ml; 10.00±0.00 %).

Effect on sperm morphology

Discussion

The male reproductive system is a complex system which consists of the hypothalamus, anterior pituitary gland, the testes and glands like the epididymis. These structures work together to maintain the potency, fertility, and male secondary sexual characteristics [15]. Spermatogenesis, the first part of sperm production which includes stem cell mitosis and meiosis, is the biological process of gradual transformation of germ cells into spermatozoa over an extended period of time within the seminiferous tubules of the testis [16]. While spermiogenesis is the final differentiation process which occurs in the haploid male germ cells [17], sperm cells are produced in the seminiferous tubules at a rate of about $2 \times 10^8$ per day in the young adult. However, spermatogenic process in rats requires 53 days, out of which the spermatozoa spends the last 6 to 7 days in the final transit through the epididymis.

There were no significant histological changes in the epididymis of the experimental rats in all the treated groups, at different doses and duration, as compared to the rats in the control group.
In this study, aqueous root extract of *Chrysophyllum albidium* was administered to the experimental rats for 28 days (4 weeks), 42 days (6 weeks) and 56 days (8 weeks), at different doses. This was done to ascertain the possible dose and duration effects of *Chrysophyllum albidium* on the sperm characteristics of the rats, as well as changes in body and organ weights. Our findings show that administration of *Chrysophyllum albidium* did not cause significant changes in body weights and organ (testes and epididymis) weights of the experimental rats irrespective of the dose and duration of extract administration. Also, the total epididymal sperm count was not significantly affected. These findings, which correlate with non-changing histology of the epididymis, may possibly indicate that the aqueous root extract of *Chrysophyllum albidium* had no adverse effect on the sperm characteristics of the experimental rats.

However, the effects on sperm motility indicates that increasing dosage and duration of administration of the aqueous root extract of *Chrysophyllum albidium* caused increased number of non-progressive sperm cells and immotile sperm cells, and decreased number of progressive motile sperm cells. This may portend possible disruption of sperm development by the extract. Disruption in the development of sperm cells could result in the production of more immotile and none progressive motile sperm cell which therefore decreases sperm motility. Sperm morphology, a relative function of the testes, was also affected by increasing dose and duration of extract administration. The number of normal sperm cells decreased while the number of abnormal sperm cells increased. Abnormal development of sperm cells in the testes, possibly caused by the extract, may lead to increase abnormal sperm cells which may compromise the fertility of the experimental rats.

Histology revealed that there were no changes in the epididymis of the test rats irrespective of the dose and duration of extract administration. The epididymis has its own blood epididymis barrier [18], contains substances such as proteins and its structure is quite different from that of the testes [19]. According to Friend and Gilula [20], the zonula occludens of the epididymis is the most highly developed, even more than the testes. These factors possibly played a major role in countering the effects of the extract on the epididymis, causing it to maintain its normal histological appearance.

**Conclusion**

Administration of aqueous root extract of *Chrysophyllum albidium* resulted in dose and duration dependent adverse effects on sperm motility and morphology which may compromise the fertility of the experimental rats.
