Evaluation of Leachate Contamination Index Obtained from Dumpsite in Onitsha, Nigeria

Emmanuel Ikpe Michael*
Nnamdi Azikiwe University, Awka, Anambra State, Nigeria

Abstract
Physico-chemical and microbiological parameters were analyzed in leachate sample obtained at different locations (Obosi public dumpsite, groundwater and agricultural soil farmland 45.6 km from Onitsha dumpsite). This is to assess the impact of leachate and the effect of heavy metals on agricultural produce, Zea mays and Phaseolus vulgaris. In addition, pH values and the concentrations of these metals (Cd, Ag, Al, Mo, As, Hg, Mn, Zn, Cu, Hi, Cr, Mg, Fe, Pb and Co) in leachate and agricultural soil collected from a depth of 10 cm were assessed. The pH of the experimental samples ranged from 6.41-7.15. The analysis of samples for heavy metals revealed very high concentrations of Mg (14.20-20.23 ppm), Hg (0.002-2.29 ppm), Pb (0.09-0.65 ppm), Cd (0.001-0.53 ppm), but Al and As were not detected in most of the samples. Physicochemical parameters (Total dissolved Solid, Temperature, Conductivity, Turbidity, Cation Exchange Capacity, Color, Total Organic Carbon and Particle size) and Microbiological parameters (Total heterotrophic bacterial and fungal count) were analyzed using standard methods. The microbial enumeration showed heterotrophic bacterial and fungal count ranging from 12 × 10^5 to 2 × 10^6 cfu/ml for leachate and ground water samples. Heterotrophic fungal count ranged from 3 × 10^5 to 8 × 10^5 cfu/ml for leachate and ground water. Culture plate, structural form and biochemical characterization conducted on these isolates using Bergey’s manual of determinative bacteriology. Fungal atlas was used to suggest possible identities of the fungal isolates. These isolates were molecularly identified by 16 S rDNA and ITS rDNA sequence analysis for bacterial and fungal isolates respectively. The bacterial identities were identified as Lysinibacillus fusiformis and Klebsiella pneumoniae, while fungal isolates were identified as Aspergillus tamarii, and Aspergillus fumigatus. The leachate generated from Obosi overburden dumpsite has the potential to pollute the surrounding water.

Keywords: Leachate; Contamination index; Heavy metals; Dumpsite; Groundwater; Toxicity

Introduction
The accumulation of waste disposed in landfills has generated a waste water product known as leachate (8). Moreover, haphazard discharge of industrial and municipal effluent can result in environmental pollution with diverse heavy metal such as (Zn, Cr, Cd, Pb) [1-11]. Consequently, these heavy metals are absorbed by plant through their root and eventually into the food chain of mammals feeding on plant for daily survival. These heavy metals are regarded to be very environmentally unfriendly. Thus, random disposal of such unexamined wastes indicates imminent harm to livelihood [5-20]. The rate of metal contamination in our soil environment result from the constant disposal of waste generated from industrial and municipal activities ranging from batteries, leads foils, glass, metallurgical process, inks, effluent of fertilizer companies and are highly recalcitrant in nature with their presence in the soil not easily be eliminate or degraded by soil organisms through metabolic processes [4,21,22]. The negative effect of heavy metals cannot be easily underestimated as it reduces the quality of soil. It has contending influence on the properties such as pH of the soil and eventually inhibiting the proliferation of microorganism due to high contamination of metal [12]. This research analysis study was geared toward evaluating the serious heavy metal contamination index of leachate collected from Onitsha dumpsite and also include the following below:

i) To determine the rates and extent of heavy metal contaminations and ascertain their distinction in pH.

ii) To evaluate the heavy metal contamination index of leachate collected from Onitsha dumpsites on agricultural and microbial implications. Bioassays were used to establish the effect of toxicity because of their sensitivity to environmental stress.

Materials and Methods

Study area
Onitsha dumpsite was selected for study due to the age and anthropogenic activities. It is cited in the latitude of 60° 05’ 39”N to 60° 12° 13” N of the equator and longitude 60° 45’ 29”E to 60° 50’ 07”E of the Green which meridian, cited at Obosi along Onitsha-Owerri expressway on the eastern bank of the River Niger.

Experimental set-up
The choice on the research using leachate was to ascertain the effect of heavy metals on the growth of plant. Beans (Phaseolus vulgaris), maize (Zea mays) were employed as bioassays. Ground water was employed as a probe using an ex situ experimental set-up. Plant subjects were supplied with dumpsite leachate and ground water in different set-up. Unsullied agricultural soil was obtained from a farmland 45.6 km from Onitsha dumpsite to ascertain significant differences.

Leachate sampling
Pooled sample of leachate collected from the dumpsite into a sterile BOD bottle and immediately preserved in an ice box (4°C) and transported to the laboratory for analysis.

Analysis of leachate organic content

The following physicochemical parameter were examined; Temperature (°C), pH, conductivity (us/cm), Turbidity (NTU), Color, total dissolved solid (mg/l).

Chemical analysis

The following metals are assessed from leachate; cadmium, silver, Aluminium, Molybdenium, Arsenic, Mercury, Magnesium, Zinc, Nickel, Chromium, Manganese, Iron, Lead and Cobalt. Heavy metals analyzed using Varian AA240 (Atomic Absorption Spectrophotometer) with method by APHA 1995 (American Public Health Association).

Analysis of soil sample (Pristine agricultural soil)

Pristine agricultural soil obtained for the experimental set-up was examined for the following physical and chemical parameters; pH, Cation Exchange capacity (mol/kg), Total organic carbon (%), %sand, %silt, %clay. Different method were of adopted for the analysis of various parameters. The pH was measured by electrometric method using laboratory pH meter Hanna model H 1991300(APHA: 1998). The analysis of Total Dissolved Solid (TDS) was adopted by APHA 1998 using APHA 2510A TDS 139 tester.

Microbiological enumeration

Analysis of the total culturable heterotrophic bacterial and fungal count was carried out using method described by Jorgensen et al. Spread plate method using nutrient agar fortified with nystatin to inhibit fungal growth and Sabouraud dextrose agar (SDA) amended with chloramphenicol to impede bacterial growth to isolate bacterial growth to isolate bacterial and fungi within the incubation period of 18-24 hrs (bacterial culture) and 18-72 hrs (fungal culture) respectively. Colonies where expressed and expressed in colony forming unit per ml (cfu/ml). The suspensions of different sample (9 ml of distilled water in 1 m samples of experimental) was prepared and serially diluted to $10^{-3}$ via serial dilution with 1 ml of leachate using distilled water as the diluents. 0.1 ml aliquots of appropriate dilutions were spread on triplicates of sterile nutrient agar.

Assessment of contamination index on pristine agriculture soil

Municipal dumpsite leachate toxicity impact was ascertained using agriculture soil and bioassays Maize (Zea may) and beans (Phaseolus vulgaris). The phytotoxicity analysis for samples was used in the cultivation of beans and maize plant as subjects. Petri dishes were used for experimental samples (leachate and ground water). 10 grains of beans and maize were planted and equally spaced in the petri dish. The experimental set-up ground water was used as control. The plants were constantly irrigated or sprinkled with leachate and ground water in this study as indicated in Table 1. The level of pollution by heavy metals in Onitsha dumpsite on seed germination as expressed in Table 3. This data indicates that Magnesium, Mercury, Molybdenium have pollution value of an extreme rate. Meanwhile, Arsenic, Aluminium, Chromium had significantly low rate of pollution and are of no threat to increase in the leachate. Lead, Cobalt, Iron was relatively high compared to the standard of USEPA in 2002 [21]. Other metals had significantly low rate of pollution and are of no threat to increase in the leachate. Lead, Cobalt, Iron was relatively high compared to the standard of USEPA in 2002 [21]. Other metals had significantly low rate of pollution and are of no threat to increase in the leachate. Lead, Cobalt, Iron was relatively high compared to the standard of USEPA in 2002 [21]. Other metals had significantly low rate of pollution and are of no threat to increase in the leachate. Lead, Cobalt, Iron was relatively high compared to the standard of USEPA in 2002 [21]. Other metals had significantly low rate of pollution and are of no threat to increase in the leachate. Lead, Cobalt, Iron was relatively high compared to the standard of USEPA in 2002 [21]. Other metals had significantly low rate of pollution and are of no threat to increase in the leachate.

Chemical analysis of agricultural soil, leachate and ground water used for experimental set-up

The cation exchange capacity (mol/kg), pH, %Total organic carbon, %silt, %clay, heavy metals (Cd, Ag, Al, Mo, As, Hg, Mn, Zn, Cu, Ni, Cr, Mg, Fe, Pb and Co) from dumpsite, leachate, agricultural soil were assessed. The pH ratio of agricultural soil, leachate and ground water samples range from 6.39-6.41, 7.14-7.16, 6.56-6.58 respectively. The ratio of soil, leachate and ground water was used for experimental set-up as indicated in Table 1. Other metals had slightly significant and insignificant ratio in the leachate, Pristine agricultural soil, ground water samples range from 6.39-6.41, 7.14-7.16, 6.56-6.58 respectively. The reason for high pH in Onitsha dumpsite leachate may obviously be due to the frequent discharge of industrial and municipal effluent into the dumpsite as compared with the pH of dumpsites in some cities in the South-West region of Nigeria such as Ekpoma (6.00 ± 0.24), Warri (5.19 ± 0.20) in previous research (1). Porousness report high pH rate in the presence of heavy metals with the range of 6.0-9.0 and this high concentration have been known to percolate into the soil of the landfill (14). The average ratio of metal concentration in the soil, leachate and ground water in this study as indicated in Table 1. The ratio of the heavy metal concentrations in the leachate sample clearly indicates the high rate of anthropogenic influence that has adversely affected the environment. The adverse effect on the experimental bioassays (Beans and Maize) indicated how it inhibited their growth and the effect of heavy metal assessment expressing their line of action in inhibiting the growth by altering their physiological activities as well as morphologically decreases the functionality of plant structures [4] (Table 2). The level of pollution by heavy metals in Onitsha dumpsite on seed germination as expressed in Table 3. This data indicates that Magnesium, Mercury, Molybdenium have pollution value of an extreme rate. Meanwhile, Arsenic, Aluminium, Chromium had significantly low rate of pollution and are of no threat to increase in the leachate. Lead, Cobalt, Iron was relatively high compared to the standard of USEPA in 2002 [21]. Other metals had slightly significant and insignificant ratio in the leachate. Leachate, soil, ground water were analyzed for physical, chemical and biological parameters like Metals, Temperature, pH, Conductivity, Turbidity, Color, Total Dissolved Solid (TDS) using standard methods of analysis.

Correlation studies

Heavy metal concentration studies in the experimental samples as shown in Figure 1. The correlation contamination index in excessive rate are categorized in the following order: Mg ≥ Fe ≥ Mn ≥ Pb ≥ Cu ≥ Ni ≥ Ag ≥ Hg ≥ Cr ≥ Al (and As) and very insignificant values (Ground water), Mg ≥ Zn ≥ Mn ≥ Cu ≥ Ni ≥ Pb ≥ Co ≥ Hg ≥ (Cr, Ag) ≥ (Al/Cd) ≥ Mo (Soil), Mg ≥ Hg ≥ Mo ≥ Pb ≥ Cd ≥ Zn ≥ Co ≥ (Ni/Cu) ≥ Ag ≥ Fe ≥ Mn ≥ (Al/Ar/Cr) for leachate. The metal correlation relatively implies that they all originate from common source. This speculation may be correct due to the fact that several industrial effluents discharged into this dumpsite originate from various combinations of these metals. Scientific researches on metals and alloys indicate that alloys of metals are combined to increase the...
purity of less valuable substances, especially during the process of electroplating metals [9,16,18].

**Data analysis**

GraphPad Prism 7.00 Software was employed for the analysis of mean values and standard deviation (± SD) using the three-mean data set result. Experimental data were obtained in replicate of three.

**Risk assessment of leachate on the growth of bioassays**

Evaluation of toxicity from the dumpsite leachate obtained for the experiment on bioassays indicated it result as an inhibitory substance due to the presence of high metals that were traceable to indiscriminate disposal of refuse and untreated industrial effluent. In accordance to the findings on the application of leachate on crops confirmed the toxicity of leachate on germinating plants [19] (Figures 2-5).

The mean correlation of germination rate of bioassays indicated in Table 4 showed that the beans and maize irrigated with leachate were inhibited as compared to that of the groundwater (control) as shown in Table 3. The germination curve of plants irrigated with leachate showed steady growth at week 1-3 and eventually reduced from week 4-7 due to the high level of toxicity from the leachate sample containing metal contaminant as their growth terminated at week 8. Steady germination rate of plants subjected to groundwater had rapid and steady growth from week 1-8 to confirm the cause of inhibition in the leachate sample experimental set-up. Srinivas et al. recorded decrease in growth of plants due to high level of heavy metals concentration. The reason for reduction of shoot length as shown in Table 4 was due to the reduced meristematic cells and certain enzymes present in the endosperm and cotyledon cells that are responsible for the digestion and storage of food to be converted to soluble form for transportation to the tip of the radical and plumule. Adverse effect of heavy metals such as Lead and Nickel on enzymatic activities affects seed germination and growth of plants [6,15,17].

**Microbial count and molecular identification**

The microbial enumeration showed heterotrophic bacterial and fungal count ranging from $12 \times 10^5$ to $2 \times 10^5$ cfu/ml for leachate and ground water samples. Heterotrophic fungal count ranged from $3 \times 10^5$ to $8 \times 10^5$ cfu/ml for leachate and ground water. The molecular identification performed by ITS rDNA sequence analysis using the FASTA algorithm with fungus data base from EBI. The fungal isolates were identified as *Aspergillus tamarii* and *Aspergillus fumigatus* and 16 S rDNA sequencing analysis, using FASTA algorithm with prokaryote

Results are Means of Triplicate Determination ± Standard Deviation (SD). NG=No Growth
The characteristics of the leachate obtained from Onitsha dumpsite, Obosi along Onitsha-Owerri expressway Anambra State of Nigeria. In this research work, it was observed that the high toxicity level of the heavy metals in leachate sample tested on bioassays (plants) inhibited germination as it decreases with increase in number of weeks. The decrease in number of germinated plants (maize and beans) was due to the high accumulation of heavy metals like Cd, Pb, Zn, and Ag especially in leachate sample. All the samples contain heavy metals in different concentration and leachate sample had the highest concentration of heavy metals against ground water that served as control.
