FLATNESS RESULTS FOR NONLOCAL MINIMAL CONES AND SUBGRAPHS

ALBERTO FARINA AND ENRICO VALDINOCI

Abstract. We show that nonlocal minimal cones which are non-singular subgraphs outside the origin are necessarily halfspaces.

The proof is based on classical ideas of [14] and on the computation of the linearized nonlocal mean curvature operator, which is proved to satisfy a suitable maximum principle.

With this, we obtain new, and somehow simpler, proofs of the Bernstein-type results for nonlocal minimal surfaces which have been recently established in [20]. In addition, we establish a new nonlocal Bernstein-Moser-type result which classifies Lipschitz nonlocal minimal subgraphs outside a ball.

1. Introduction

Recently, a Bernstein-type problem for nonlocal minimal surfaces has been settled in [20]. The two main results of [20] consist in:

• first, a “Lipschitz implies $C^\infty$” regularity result for nonlocal minimal surfaces,

• then, a “no singular cones implies Bernstein Theorem in one more dimension”.

The precise statements of these results will be explicitly recalled later on, in Theorems 2 and 3. From these results, one obtains also interesting byproducts, such as the fact that $s$-minimal subgraphs are necessarily flat if the ambient space has dimension less than or equal to 3, or less than or equal to 8 under the additional assumption that the fractional parameter is large enough.

The goal of this paper is to establish that nonlocal minimal cones with the structure of a non-singular subgraph outside the origin are necessarily flat. Interestingly, this result holds in any dimension and provides also a nonlocal version of the Bernstein Theorem for classical minimal surfaces proved by J. Moser in [27]. As a byproduct, we also obtain new results for $s$-minimal subgraphs outside a ball. Furthermore, the approach of this paper presents an alternative, and somehow simpler, proof of the results in [20].

The mathematical setting in which we work is that introduced in [5], that we now recall. We consider an ambient space of dimension $N := n + 1 \in \mathbb{N}$. For any disjoint (measurable) subsets $X$ and $Y$ of $\mathbb{R}^N$ and any $s \in (0, 1)$, we consider the $s$-interaction of $X$ and $Y$, defined by

$$\mathcal{J}_s(X, Y) := \int\int_{X \times Y} \frac{dx \, dy}{|x - y|^{N+s}}.$$

Given a (say, bounded and Lipschitz) set $\Omega \subset \mathbb{R}^N$, and $E \subset \mathbb{R}^N$, one defines the $s$-perimeter of $E$ in $\Omega$ as the sum of all the interactions of $E$ and $E^c := \mathbb{R}^n \setminus \Omega$ to which the domain $\Omega$ contributes, namely

$$\text{Per}_s(E, \Omega) := \mathcal{J}_s(E \cap \Omega, \ E^c \cap \Omega) + \mathcal{J}_s(E \cap \Omega^c, \ E^c \cap \Omega^c) + \mathcal{J}_s(E \cap \Omega^c, \ E^c \cap \Omega).$$

As customary, the superscript “c” denotes the complementary set. Then, one says that $E$ is an $s$-minimal set in $\Omega$ (or that $\partial E$ is an $s$-minimal surface in $\Omega$) if it is a local minimizer in $\Omega$ of the $s$-perimeter functional, i.e. if $\text{Per}_s(E, \Omega) < +\infty$ and

$$\text{Per}_s(E, \Omega) \leq \text{Per}_s(F, \Omega)$$

for every $F \subset \mathbb{R}^N$ such that $F \cap \Omega^c = E \cap \Omega^c$.

We also say that $E$ is an s-minimal set if it is an s-minimal set in $B_R$ for all $R > 0$.

The study of s-minimal surfaces is extremely challenging and fascinating, and their complete regularity theory is one of the most important open problems in the topic of fractional analysis. Till now, it is known that s-minimal surfaces are $C^\infty$ in the interior of the reference domain when the dimension $N$ of the ambient space is less than or equal than 3 (see [30]) and when the dimension $N$ of the ambient space is less than or equal than 8 as long as the fractional exponent $s$ is sufficiently close to 1 (see [7] and also [2]).

The boundary regularity is somehow a different story with respect to the interior case, since s-minimal surfaces have the tendency to stick at the boundary of the domain and to detach in a $C^{1,\frac{1+s}{2}}$ fashion from it, see [4,17].

Nonlocal perimeters and nonlocal minimal surfaces have also a number of applications, and they naturally arise for instance as interfaces of long-range phase coexistence models (see [29]) and models for cellular automata (see [6]). An intense research activity has been done concerning nonlocal isoperimetric problems (see e.g. [23,21,22,19]) constant nonlocal mean curvature surfaces (see e.g. [3,10] and also [12]) and nonlocal geometric flows (see [25,8,28,9]), and the topic is rich of very challenging and important open questions, with many links to other subjects, see e.g. [11,18] for recent surveys.

We say that a set $E$ is a cone (with respect to the origin) if for every $p \in E$ we have that $tp \in E$ for any $t \geq 0$.

We say that a set $E \subseteq \mathbb{R}^N$ is an s-minimal cone if it is an s-minimal set and it is a cone.

It is also interesting to consider the case in which sets have the structure of subgraphs (say, for definiteness, with respect to the last coordinate). That is, we say that $E \subseteq \mathbb{R}^N = \mathbb{R}^n + 1$ is a subgraph if there exists a (measurable) function $u : \mathbb{R}^n \to \mathbb{R}$ such that

$$E = \{x_{n+1} < u(x_1, \ldots, x_n)\}.$$  

We say that $E$ is an s-minimal subgraph if it is an s-minimal set and a subgraph.

We remark that the notion of subgraph fits well into the nonlocal minimal surface setting, since if one considers cylindrical domains $\Omega = \Omega_0 \times \mathbb{R} \subset \mathbb{R}^{n+1}$ with $\Omega_0 \subset \mathbb{R}^n$ and prescribes the data of the set outside $\Omega$ to be a subgraph, then the s-minimal sets in $\Omega$ possess a subgraph structure, though with possible discontinuities along the boundary of the cylinder (see [16], and this boundary discontinuity is an important difference with respect to the classical minimal surfaces).

In this context, the main result of this paper is the following:

**Theorem 1.** Let $n \geq 1$ and $E$ be an s-minimal cone in $\mathbb{R}^{n+1}$. Assume that $E$ is a subgraph, as in (1.1).

Suppose that

$$u \text{ is locally Lipschitz continuous in } \mathbb{R}^n \setminus \{0\}.$$  

Then $E$ is a halfspace.

This result is the nonlocal analogue of that on page 79 of [14] for the minimizers of the classical perimeter functional.

Theorem 1 can be also recasted for conical subgraphs with zero fractional mean curvature. For this, given $E \subset \mathbb{R}^N$ and $x \in \partial E$, with $\partial E$ of class $C^{1,\alpha}$ with $\alpha > s$ at $x$, we define the s-mean curvature of $E$ at $x$ as

$$\mathcal{H}_s^E(x) := \int_{\mathbb{R}^n} \frac{\chi_{E^c}(y) - \chi_E(y)}{|x-y|^{n+s}},$$

As a “philosophical remark”, let us mention that the exponent $\frac{1+s}{2}$ is somehow consistent with the kernel in computations like that in (3.2) in this paper, in which the kernel is of the form $n + 2S$, with $S := \frac{1+s}{2}$. These types of operators are sort of nonlinear $S$-Beltrami Laplacian along manifolds of dimension $n$ embedded into $\mathbb{R}^N = \mathbb{R}^{n+1}$.
in the principal value sense. See \([5,1,26,19]\) for the basic properties of \(H^s\) and for the fact that it can be considered as the first variation of \(\text{Per}_s\). In this setting, one can restate Theorem 1 by saying that if a set is a subgraph and a cone, that is smooth outside the origin, and with \(H^s = 0\) on \(\partial E \setminus \{0\}\), then it must be a halfspace. The structural assumptions of such statement are somehow sharp, since the cones discussed in Theorem 3 of \(13\) are smooth outside the origin and have zero fractional mean curvature in any dimension, without being halfspaces (but such cones are not subgraphs).

As an immediate consequence of Theorem 1, we obtain a new proof of the following two results, which have been recently proved, with other methods, in \(20\):

**Theorem 2** (Theorem 1.1 in \(20\)). Let \(n \geq 1\) and let \(E\) be an \(s\)-minimal set in \(B_1 \subset \mathbb{R}^{n+1}\). Suppose that \(\partial E \cap B_1\) is locally Lipschitz. Then \(\partial E \cap B_1\) is \(C^\infty\).

**Theorem 3** (Theorem 1.2 in \(20\)). Let \(E = \{x_{n+1} < u(x_1, \ldots, x_n)\}\) be an \(s\)-minimal subgraph, and assume that there are no singular \(s\)-minimal cones in dimension \(n\) (that is, if \(C \subset \mathbb{R}^n\) is a non-empty \(s\)-minimal cone, then \(C\) is a halfspace). Then \(u\) is an affine function (thus \(E\) is a halfspace).

The proofs of Theorems 2 and 3 are based on the classification of blow-up and blow-down cones respectively (see e.g. Section 3 in \(20\) or Section 2 here for a detailed discussion on blow-up and blow-down cones). In \(20\) such classification of limit cones is obtained by geometric methods: roughly speaking, the idea in \(20\) is to use the cone itself as a barrier, modifying it in a given region by adding a “small bump” to the original cone and sliding this modified surface to a first contact point with the original one (on the one hand, the effect of this bump should change only by little the nonlocal mean curvature at a smooth point, on the other hand such nonlocal mean curvature is influenced from far-away points by an order one contribution in a non-flat picture, and these two observations provide a contradiction).

Very roughly speaking, the idea for the argument of \(20\) is quite geometric and sketched in Figure 1 (after a dilation, for instance, the subgraph reduces to a cone, which is touched from below by the dashed surface, which should have a small nonlocal mean curvature if the additional bump is small, in contradiction with the mass produced in the grey region).

In this paper instead we obtain Theorems 2 and 3 directly from Theorem 1 which classifies the blow-up and blow-down cones without any other additional geometric argument and only relying on analytical methods, such as linearization and maximum principle.

It is also interesting to point out that our results can also comprise the more general settings of subgraphs outside a ball. Namely, we say that \(E \subseteq \mathbb{R}^N = \mathbb{R}^{n+1}\) is a subgraph outside a ball if there exists a ball \(B \subset \mathbb{R}^n\) and a function \(u : \mathbb{R}^n \to \mathbb{R}\) such that
\[
E \setminus (B \times \mathbb{R}) = \{x_{n+1} < u(x_1, \ldots, x_n)\} \setminus (B \times \mathbb{R}).
\]
We say that \(E\) is an \(s\)-minimal subgraph outside a ball if it is an \(s\)-minimal set and a subgraph outside a ball.

The setting that we provide in Theorem 1 is strong enough to establish a classification result for Lipschitz \(s\)-minimal subgraphs outside a ball, which goes as follows:
Theorem 4. Let $n \geq 1$ and $E$ be an $s$-minimal subgraph outside an open ball $B$, as in (1.3). Suppose also that
\begin{equation}
\text{(1.4)} \quad u \text{ is globally Lipschitz continuous in } \mathbb{R}^n \setminus B.
\end{equation}
Then $E$ is a halfspace.

Theorem 4 can be seen as the nonlocal counterpart of the results for classical minimal surfaces that were obtained in Section 7 of [27] by means of Harnack-type inequalities. As far as we know, Theorem 4 is new even for $s$-minimal subgraphs as in (1.1).

We also point out that a strengthening of Theorem 2 holds true, where one can drop the Lipschitz assumption if no singular cones exist in one dimension less, according to the following statement:

Theorem 5. Let $n \geq 1$ and let $E$ be an $s$-minimal subgraph in $B_1 \subset \mathbb{R}^{n+1}$. Assume also that there are no singular $s$-minimal cones in dimension $n$. Then $\partial E \cap B_1$ is $C^\infty$.

Corollary 6. Let $n \in \{1, 2\}$ and let $E$ be an $s$-minimal subgraph in $B_1 \subset \mathbb{R}^{n+1}$. Then $\partial E \cap B_1$ is $C^\infty$.

Similarly, from Theorem 5 here and Theorem 2 in [7], we obtain:

Corollary 7. Let $n \in \{1, \ldots, 7\}$. Then there exists $\varepsilon_n \in (0, 1)$ such that if $s \in (1 - \varepsilon_n, 1)$ and $E$ is an $s$-minimal subgraph in $B_1 \subset \mathbb{R}^{n+1}$, it holds that $\partial E \cap B_1$ is $C^\infty$.

Corollaries 6 and 7 can be seen as a positive answer when $n \in \{1, 2\}$ (or when $n \in \{1, \ldots, 7\}$ and $s$ is close enough to 1) to the Open Problem in Section 7.3 of [11].

The rest of this paper is mostly devoted to the proof of Theorem 1, which in turn will imply Theorems 2 and 3 right away. We then give the proofs of Theorems 4 and 5 by exploiting Theorem 1. Before presenting the main arguments of the proof of Theorem 1 we present some basic facts about blow-up and blow-down cones.

The paper ends with an appendix collecting some ancillary (but nontrivial) estimates to check that some integrals are well-defined and can be differentiated.

2. An overview on blow-up and blow-down cones for $s$-minimal sets

Given an $s$-minimal set $E$, with $0 \in \partial E$, for any $r > 0$, we consider the family of sets $E_r := E/r$. By density estimates and monotonicity formulas, we know that $E_r$ converges up to subsequences to some $E_0$ as $r \searrow 0$ and to some $E_\infty$ as $r \nearrow +\infty$. In addition, the sets $E_0$ and $E_\infty$ are $s$-minimal cones, see Theorem 9.2 in [5].

The cone $E_0$, which is called in jargon “blow-up cone”, corresponds to the action of “looking the picture close to the origin by performing a zoom-in” and its flatness is equivalent to the regularity of the original set $E$ in a neighborhood of the origin. Indeed, from Theorem 6.1 in [5] and Theorem 5 in [2], we have that
\begin{equation}
\text{(2.1)} \quad \text{if } E_0 \text{ is a halfspace, then } \partial E \cap B_\rho \text{ is } C^\infty,
\end{equation}
for some $\rho > 0$.

The cone $E_\infty$ is called in jargon “blow-down cone” and corresponds to the action of “looking the picture from far, by making a zoom-out” and its flatness is equivalent to the flatness of the original set $E$. Indeed, we have that
\begin{equation}
\text{(2.2)} \quad \text{if } E_\infty \text{ is a halfspace, then } E = E_\infty, \text{ and so } E \text{ is a halfspace.}
\end{equation}
See e.g. Lemma 3.1 in [20].

Moreover, we recall the following dimensional reduction of Theorem 10.3 in [5] (see also Theorem 5.33 in [26]):
Lemma 8. Let $E$ be an s-minimal cone in $\mathbb{R}^{n+1}$. Let $p \in \partial E$, with $p \neq 0$.

Let $F := E - p$ and let $F_0$ be the blow-up cone for $F$.

Then $F_0$ can be written up to a rotation as the Cartesian product $\hat{F} \times \mathbb{R}$, where $\hat{F}$ is an s-minimal cone in $\mathbb{R}^n$.

Also, if $\partial E$ is not $C^\infty$ at $p$, then $\hat{F}$ is singular at the origin.

From Lemma 8 we obtain that if no singular s-minimal cones exist in one dimension less, then the origin is the only possible singularity of s-minimal cones (i.e. if no singular s-minimal cones exist in $\mathbb{R}^n$, then the s-minimal cones in $\mathbb{R}^{n+1}$ are either halfspaces or singular only at the origin):

Corollary 9. Let $E$ be an s-minimal cone in $\mathbb{R}^{n+1}$. Assume that there are no singular s-minimal cones in dimension $n$. Then, $\partial E$ is $C^\infty$ outside the origin.

Proof. Suppose, by contradiction, that $\partial E$ is not $C^\infty$ at some point $p \in \partial E$, with $p \neq 0$. Then Lemma 8 produces a singular minimal cone $\hat{F}$ in $\mathbb{R}^n$, which is in contradiction with our assumption.

The dimension reduction of Lemma 8 can be strengthen in case of Lipschitz subgraphs. To this end, we first give a detailed blow-up argument when a Lipschitz assumption is taken:

Lemma 10. Let $E$ be an s-minimal cone in $\mathbb{R}^{n+1}$. Let $\kappa \in \mathbb{R}$ and $p = (0, \ldots, 0, 1, \kappa) \in \partial E$ and suppose that $\partial E$ is a Lipschitz subgraph in a neighborhood of $p$.

Let $F := E - p$ and let $F_0$ be the blow-up cone for $F$. Then, $F_0$ is the subgraph of some Lipschitz function $v_0 : \mathbb{R}^n \to \mathbb{R}$. Furthermore, there exists a Lipschitz function $v^* : \mathbb{R}^{n-1} \to \mathbb{R}$ such that

$$v_0(\hat{x}, x_n) = v^*(\hat{x}) + \kappa x_n,$$

for any $(\hat{x}, x_n) \in \mathbb{R}^{n-1} \times \mathbb{R}$.

In addition, for any $t \geq 0$ and any $\hat{x} \in \mathbb{R}^{n-1}$,

$$v^*(t\hat{x}) = tv^*(\hat{x}).$$

Furthermore, if $\left(-\frac{\pi}{2}, \frac{\pi}{2}\right) \ni \theta := \arctan \kappa$ and we consider the rotation given by

$$\mathbb{R}^{n-1} \times \mathbb{R} \times \mathbb{R} \ni (\hat{y}, y_n, y_{n+1}) := \mathcal{R}_\theta(\hat{x}, x_n, x_{n+1}),$$

with $\hat{y} := \hat{x}$,

$$\begin{pmatrix} y_n \\ y_{n+1} \end{pmatrix} := \begin{pmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{pmatrix} \begin{pmatrix} x_n \\ x_{n+1} \end{pmatrix},$$

we have that $\mathcal{R}_\theta(F_0) = F^* \times \mathbb{R}$, where $F^*$ is an s-minimal cone in $\mathbb{R}^n$ (with variables $(\hat{y}, y_{n+1})$) and it is the subgraph $\{y_{n+1} < \cos \theta v^*(\hat{y})\}$.

Proof. We let $e_n := (0, \ldots, 0, 1) \in \mathbb{R}^n$ and $e_{n+1} := (0, \ldots, 0, 0, 1) \in \mathbb{R}^{n+1}$. In this way, we can write $p = (e_n, 0) + \kappa e_{n+1}$. We let $u$ be the subgraph describing $E$ near $p$ and $v(x) := u(x + e_n) - \kappa$. The function $v$ describes the subgraph of $F$ near the origin. Let $M > 0$ be the Lipschitz constant of $u$ in $B_{\rho}(e_n)$, for some $\rho > 0$. Then the Lipschitz constant of $v$ in $B_{\rho/\gamma}$ is bounded by $M$.

We also define $v_r(x) := \frac{v(rx)}{r}$. By construction, $v(0) = u(e_n) - \kappa = 0$ and so $v_r(0) = 0$. Also, the Lipschitz constant of $v$ in $B_{\rho/\gamma}$ is bounded by $M$. Consequently, from the Arzelà-Ascoli Theorem, up to subsequence, as $r \searrow 0$, $v_r$ converges locally uniformly to some Lipschitz function $v_0$.

Now, since $E$ is a cone, for any $\hat{y} \in \mathbb{R}^{n-1}$ and $t \geq 0$, we have that

$$u(t\hat{y}, t) = tu(\hat{y}, 1).$$

Accordingly, fixed $\hat{x} \in \mathbb{R}^{n-1}$ and $\tau \geq -\frac{1}{r}$, taking $t := r\tau + 1 \geq 0$ and $\hat{y} := \frac{r\hat{x}}{r\tau + 1} = \frac{r\hat{x}}{t}$, we see that

$$v(r\hat{x}, r\tau) = u(r\hat{x}, r\tau + 1) - \kappa = u(t\hat{y}, t) - \kappa = tu(\hat{y}, 1) - \kappa = \frac{r\hat{x}}{r\tau + 1} u(\hat{y}, 1) + u(\hat{y}, 1) - \kappa$$

$$= r\tau u\left(\frac{r\hat{x}}{r\tau + 1}, 1\right) + u\left(\frac{r\hat{x}}{r\tau + 1}, 1\right) - \kappa.$$
and thus

\begin{equation}
(2.6) \quad v_r(\hat{x}, \tau) = \tau u \left( \frac{r \hat{x}}{r \tau + 1}, 1 \right) + \frac{u \left( \frac{r \hat{x}}{r \tau + 1}, 1 \right) - u(r \hat{x}, 1)}{r} + \frac{u(r \hat{x}, 1) - \kappa}{r}.
\end{equation}

So, we now fix $\tau \in \mathbb{R}$ and $\hat{x} \in \mathbb{R}^{n-1}$. We take $r > 0$ so small that $\tau \geq - \frac{1}{r}$. Also, for small $r$, we have that $(\frac{r \hat{x}}{r \tau + 1}, 1)$ and $(r \hat{x}, 1)$ belong to $B_{\rho/2}(e_n)$ and therefore

\begin{equation}
(2.7) \quad \left| u \left( \frac{r \hat{x}}{r \tau + 1}, 1 \right) - u(r \hat{x}, 1) \right| \leq \frac{M |r \hat{x}|}{r} \leq M |\hat{x}| |\tau| r, \quad \text{which is infinitesimal as } r \searrow 0.
\end{equation}

We also set $w_r(\hat{x}) := \frac{u(r \hat{x}, 1) - \kappa}{r}$. Notice that $w_r(0) = \frac{u(0,1) - \kappa}{r} = 0$, and $w_r$ has Lipschitz constant locally bounded by $M$ when $r$ is small. Thus, up to a subsequence, we suppose that $w_r$ converges locally uniformly to a Lipschitz function $v^*$. Using this information and (2.7), we can pass to the limit in (2.6) and conclude that

\begin{equation}
(2.8) \quad v_0(\hat{x}, \tau) = \lim_{r \searrow 0} v_r(\hat{x}, \tau) = \lim_{r \searrow 0} \tau u \left( \frac{r \hat{x}}{r \tau + 1}, 1 \right) + \frac{u \left( \frac{r \hat{x}}{r \tau + 1}, 1 \right) - u(r \hat{x}, 1)}{r} + w_r(\hat{x}) = \tau u(0,1) + v^*(\hat{x}) = \kappa \tau + v^*(\hat{x}).
\end{equation}

This establishes (2.3), as desired.

Now, from (2.3) and the fact that $F_0$ is a cone, we have that

\begin{equation}
\left( v^*(t \hat{x}) + \kappa tx_n \right) = v_0(t \hat{x}, tx_n) = tv_0(\hat{x}, x_n) = t(v^*(\hat{x}) + \kappa x_n) = tv^*(\hat{x}) + \kappa tx_n,
\end{equation}

from which (2.4) easily follows.

Now, we consider the rotation in (2.5), and we perform a geometric argument to complete the proof of Lemma 10, as described by Figure 2.
The analytic details go as follows. We substitute \( \dot{x} = \dot{y}, \ x_n = \cos \theta y_n - \sin \theta y_{n+1} \) and \( x_{n+1} = \sin \theta y_n + \cos \theta y_{n+1} \). In this way, we have that
\[
R_\theta(F_0) = R_\theta\left( \{ x_{n+1} < v_0(\dot{x}, x_n) \} \right)
= R_\theta\left( \{ x_{n+1} < v^*(\dot{x}) + \tan \theta x_n \} \right)
= \{ \sin \theta y_n + \cos \theta y_{n+1} < v^*(\dot{y}) + \tan \theta (\cos \theta y_n - \sin \theta y_{n+1}) \}
= \{ (\cos \theta + \tan \theta \sin \theta)y_{n+1} < v^*(\dot{y}) \}
= \{ y_{n+1} < \cos \theta v^*(\dot{y}) \}
= \{ (\dot{y}, y_n, y_{n+1}) \text{ with } y_{n+1} < \cos \theta v^*(\dot{y}) \text{ and } y_n \in \mathbb{R} \}.
\]
This gives the desired expression for \( F^* \). Also, since \( F_0 \) is \( s \)-minimal in \( \mathbb{R}^{n+1} \), so is \( R_\theta(F_0) = F^* \times \mathbb{R} \) and then \( F^* \) is \( s \)-minimal in \( \mathbb{R}^n \) by dimension reduction (see Theorem 10.3 in [5] or Theorem 5.33 in [26]).

3. PROOF OF THEOREM 1

The idea of the proof, inspired by the work in [14] (with the very minor correction in [15]), is based on two observations:

- the derivatives of \( u \) should satisfy a linearized equation,
- since \( E \) is a cone, these derivatives are positively homogeneous of degree zero, and therefore their maxima and minima along the unit sphere must be global maxima and minima.

Then, if the linearized equation possesses a maximum, or minimum, principle, the derivatives of \( u \) are necessarily constant, hence \( u \) must be affine and \( E \) is proved to be a halfspace, as desired.

In our setting, the goal is thus to write an appropriate equation for \( u \) and for its derivatives and check that a suitable maximum principle is satisfied for such linearized equation. The main idea for this is that the fractional mean curvature of \( E \) at any boundary point must vanish (see Theorem 5.1 [5] or Corollary 4.13 in [26]). Then, by some computation one can write such fractional mean curvature directly in term of the function \( u \): this expression is not completely explicit, since one cannot write “simple expressions” of all the integrals involved, nevertheless the formulas that we provide (which can be useful in other contexts as well) are suitable to carry out detailed analytic arguments. Indeed, outside the origin the function \( u \) is differentiable and the fractional mean curvature equation can be linearized. A careful inspection of the sign of the integrands reveals that this linearized equation “charges positive masses” and so it possess a sort of maximum principle, which in turn provides the desired result.

In further details, the analytical ingredients which effectively implement this general strategy go as follows. We write \( E \) as a subgraph, as in (1.1). First, we establish Theorem 1 under the additional assumption that
\[
(3.1) \quad u \in C^0(\mathbb{R}^n \setminus \{0\}).
\]
Since \( E \) is \( s \)-minimal, at any point \( X = (x, u(x)) \in \mathbb{R}^{n+1} \), with \( x \in \mathbb{R}^n \setminus \{0\} \), we have that the fractional mean curvature of \( E \) at \( X \) must vanish (see Theorem 5.1 in [5] or Corollary 4.13 in [26]). We also consider the tangent halfspace at \( X \), namely
\[
L_X := \{ Y = (y, y_{n+1}) \in \mathbb{R}^n \times \mathbb{R} \text{ s.t. } y_{n+1} < \nabla u(x) \cdot (y - x) + u(x) \}.
\]
Of course, the fractional mean curvature of \( L_X \) at \( X \) must vanish as well. Notice in addition that
\[
\chi_E - \chi_L = \begin{cases} 1 & \text{in } E \cap L^c, \\ -1 & \text{in } L \cap E^c, \\ 0 & \text{otherwise} \end{cases}
\]
and similarly
\[
\chi_{E^c} - \chi_{L^c} = \begin{cases} 
1 & \text{in } E^c \cap L \\
-1 & \text{in } L^c \cap E \\
0 & \text{otherwise}
\end{cases}
\]
These considerations imply that, for any \( X = (x, x_{n+1}) = (x, u(x)) \in \mathbb{R}^n \times \mathbb{R} \), with \( x \neq 0 \),
\[
0 = \frac{1}{2} \int_{\mathbb{R}^N} \frac{\left(\chi_{E^c}(Y) - \chi_{L^c}(Y)\right) - \left(\chi_{E}(Y) - \chi_{L}(Y)\right)}{|X - Y|^{n+s}} \, dY
\]
(3.2)
where, for any \( r \in \mathbb{R} \),
\[
\int_{\mathbb{R}^n} \frac{dY}{|X - Y|^{n+1+s}} = \int_{\mathbb{R}^n} \frac{dY}{|X - Y|^{n+s}} - \int_{\mathbb{R}^n} \frac{dY}{|X - Y|^{n+1+s}}
\]
Now, fixed \( X = (x, x_{n+1}) \in \mathbb{R}^n \times \mathbb{R} \), given two functions \( f, g : \mathbb{R}^n \to \mathbb{R} \), with \( f(x) = g(x) = x_{n+1} \), we use the substitutions
\[
\mathbb{R} \ni \tau := \frac{y_n + x_{n+1}}{|y - x|} \quad \text{and} \quad \mathbb{R}^n \ni \vartheta := y - x
\]
to make the following calculation:
\[
\int_{\mathbb{R}^n} \frac{dY}{|X - Y|^{n+1+s}} = \int_{\mathbb{R}^n} \frac{dY}{|X - Y|^{n+s}} - \int_{\mathbb{R}^n} \frac{dY}{|X - Y|^{n+1+s}}
\]
(3.3)
where, for any \( r \in \mathbb{R} \), we used the notation\(^2\)
\[
F(r) := \int_0^r \frac{d\tau}{(1 + \tau^2)^{\frac{n+1+s}{2}}}
\]
Making use of (3.3) into (3.2), with the choice \( f(y) := u(y) \) and \( g(y) := \nabla u(x) \cdot (y - x) + u(x) \), we conclude that
\[
\mathcal{F}[u](x) := \int_{\mathbb{R}^n} \frac{F\left(\frac{u(x) - u(x)}{|\vartheta|} - F\left(\frac{\nabla u(x) \cdot \vartheta}{|\vartheta|}\right)\right)}{|\vartheta|^{n+s}} \, d\vartheta = 0,
\]
for any \( x \in \mathbb{R}^n \setminus \{0\} \).
To avoid integrals in the principal value sense, it is now convenient to produce a “more symmetric” version of (3.5), by taking into account the fact that \( F(r) = \frac{1}{(1 + r^2)^{\frac{n+1+s}{2}}} \), which is an even function, and so \( F \) is an odd function. Therefore, the change of variable \( \vartheta \mapsto -\vartheta \) gives that
\[
\int_{\mathbb{R}^n} \frac{F\left(\frac{u(x) - u(x)}{|\vartheta|} - F\left(\frac{\nabla u(x) \cdot \vartheta}{|\vartheta|}\right)\right)}{|\vartheta|^{n+s}} \, d\vartheta = \int_{\mathbb{R}^n} \frac{F\left(\frac{u(x) - u(x)}{|\vartheta|} - F\left(\frac{\nabla u(x) \cdot \vartheta}{|\vartheta|}\right)\right)}{|\vartheta|^{n+s}} \, d\vartheta
\]
(3.4)
\[
= \int_{\mathbb{R}^n} \frac{F\left(\frac{u(x) - u(x)}{|\vartheta|} + F\left(\frac{\nabla u(x) \cdot \vartheta}{|\vartheta|}\right)\right)}{|\vartheta|^{n+s}} \, d\vartheta
\]
\(^2\)The function \( F \) was introduced in formula (49) of [2]. See also [3] for other applications of such function in related contexts.
Summing up this to (3.5), we conclude that

\[
(3.6) \quad 2\mathcal{F}[u](x) := \int_{\mathbb{R}^n} \frac{F\left(\frac{u(x+\vartheta)-u(x)}{\left|\vartheta\right|}\right) + F\left(\frac{u(x-\vartheta)-u(x)}{\left|\vartheta\right|}\right)}{\left|\vartheta\right|^{n+s}} \, d\vartheta = 0.
\]

One can check that

\[
(3.7) \quad \text{the integral in (3.6) is well-posed, see Appendix (A). Then, for any } j \in \{1, \ldots, n\} \text{ we take}^3 \text{ a derivative of (3.6) and we obtain that } v := \partial_j u \text{ satisfies the linearized equation}
\]

\[
(3.8) \quad \mathcal{L}_u[v](x) := \int_{\mathbb{R}^n} \frac{F'\left(\frac{u(x+\vartheta)-u(x)}{\left|\vartheta\right|}\right) \left(v(x+\vartheta) - v(x)\right) + F'\left(\frac{u(x-\vartheta)-u(x)}{\left|\vartheta\right|}\right) \left(v(x-\vartheta) - v(x)\right)}{\left|\vartheta\right|^{n+s+1}} \, d\vartheta = 0.
\]

The fact that the derivative in (3.6) can be safely taken, thus leading to (3.8) is checked in details in Appendix B.

Now we claim that

\[
(3.9) \quad v \text{ is constant.}
\]

The proof of (3.9) is based on the maximum principle, applied to the linearized equation in (3.8). In order to achieve this aim, we take \(\bar{x} \in S^{n-1}\) be such that

\[
v(\bar{x}) = \max_{S^{n-1}} v.
\]

Since \(E\) is a cone, it follows that \(u\) is positively homogeneous of degree one, and so \(v\) is positively homogeneous of degree zero. As a result, it follows that, for any \(x \in \mathbb{R}^n \setminus \{0\}\),

\[
v(x) = v\left(\frac{x}{|x|}\right) \leq \max_{S^{n-1}} v = v(\bar{x}).
\]

Consequently, we have that

\[
v(\bar{x} \pm \vartheta) - v(\bar{x}) \leq 0,
\]

and this expression vanishes identically for \(\vartheta \in \mathbb{R}^n\) if and only if \(v\) is constant. Also, by (3.4), we have that

\[
F'\left(\frac{u(\bar{x} \pm \vartheta) - u(x)}{|\vartheta|}\right) > 0.
\]

Therefore, the map

\[
\mathbb{R}^n \ni \vartheta \mapsto \frac{F'\left(\frac{u(\bar{x}+\vartheta)-u(x)}{\left|\vartheta\right|}\right) \left(v(\bar{x}+\vartheta) - v(\bar{x})\right) + F'\left(\frac{u(\bar{x}-\vartheta)-u(x)}{\left|\vartheta\right|}\right) \left(v(\bar{x}-\vartheta) - v(\bar{x})\right)}{\left|\vartheta\right|^{n+s+1}}
\]

is non-positive, and strictly negative on a positive measure set of \(\vartheta\)'s, unless \(v\) is constant. This observation and (3.8) imply (3.9).

In view of (3.9), we have therefore completed the proof of Theorem 1 under the additional assumption in (3.1).

\[3\]We also observe that, in (3.8), one can also write the short-hand expression

\[
\mathcal{L}_u[v](x) = 2 \int_{\mathbb{R}^n} \frac{F'\left(\frac{u(x+\vartheta)-u(x)}{\left|\vartheta\right|}\right) \left(v(x+\vartheta) - v(x)\right)}{\left|\vartheta\right|^{n+s+1}} \, d\vartheta,
\]

provided that the integral is taken in the principal value sense.
We now remove this additional hypothesis. To this end, we first make the following general observation:

if \( G \) is an \( s \)-minimal set

\[
(3.10) \quad \text{which is a Lipschitz continuous subgraph in a neighborhood of the origin, with } 0 \in \partial G,
\]

then its blow-up cone \( G_0 \) is a subgraph and it is globally Lipschitz continuous.

To check this, let us suppose that \( G \), in some \( B_\rho \subset \mathbb{R}^n \), is the subgraph of a function \( v \) with Lipschitz constant bounded by some \( M > 0 \) in \( B_\rho \). Then \( G_r := G/r \) is the subgraph of \( v_r(x) := v(rx) \) in \( B_{\rho/r} \).

Since \( v_r(0) = 0 \) and the Lipschitz constant of \( v_r \) is bounded by \( M \) in \( B_{\rho/r} \), it follows from the Arzelà-Ascoli Theorem that, as \( r \searrow 0 \), \( v_r \) converges locally uniformly to some \( v_0 \), which has Lipschitz constant bounded by \( M \). These considerations prove \((3.10)\).

Now, to remove the additional assumption in \((3.1)\), we suppose that there exists \( p \in \partial E \), \( p \neq 0 \), at which \( E \) is not of class \( C^3 \). By Lemma 10, by a blow-up at \( p \), we obtain a Lipschitz subgraph \( F^* \) which is an \( s \)-minimal cone in \( \mathbb{R}^n \) that is singular at the origin.

Suppose first that \( F^* \) is \( C^3 \) outside the origin. But then we could apply Theorem 1 under the additional assumption in \((3.1)\) and conclude that \( F^* \) is a halfspace, which is a contradiction.

Hence, there must be a boundary point \( q \neq 0 \) at which \( F^* \) is not \( C^3 \). But then we can apply again Lemma 10 (i.e. we can blow-up \( F^* \) at the point \( q \)), and find a new \( s \)-minimal cone in dimension \( n - 1 \). Hence, by repeating the blow-up argument at most a finite number of times, we reach a contradiction, thus completing the proof of Theorem 1 in its full generality. \( \square \)

4. PROOF OF THEOREM 2

The blow-up cone \( E_0 \) constructed before formula (4.3) in \[20\] satisfies the assumptions of Theorem 1 and so it is a halfspace. From this and \((2.2)\), Theorem 2 plainly follows. \( \square \)

5. PROOF OF THEOREM 3

The blow-down cone \( E_\infty \) constructed before formula (5.1) in \[20\] satisfies the assumptions of Theorem 1 and so it is a halfspace. From this, Theorem 3 plainly follows. \( \square \)

6. PROOF OF THEOREM 4

Without loss of generality, we suppose that \( B = B_1 \). We look at the blow-down limit of \( E \). That is, up to a translation, we assume that the origin belongs to the boundary of \( E \) and we consider the blow-down cone \( E_\infty \). We claim that

\[
(6.1) \quad E_\infty \text{ is a Lipschitz subgraph.}
\]

For this, we write

\[
E_r = \frac{E}{r} = \left\{ \left( y, y_{n+1} \right) \in \mathbb{R}^{n+1} \mid \text{s.t. } y = \frac{x}{r}, \ y_{n+1} = \frac{x_{n+1}}{r} \text{ and } x_{n+1} < u(x) \right\}
\]

\[
= \left\{ \left( y, \frac{u(ry)}{r} - \mu \right), \text{ with } y \in \mathbb{R}^n \text{ and } \mu > 0 \right\}.
\]

We recall \((1.4)\), which also implies that \( u \) is continuous along \( \partial B \subset \mathbb{R}^n \setminus B \), and we take \( M > 0 \) which controls \(|u| \) along \( \partial B_1 \) and the Lipschitz constant of \( u \) in \( \mathbb{R}^n \setminus B_1 \). Then, for any \( x \in \mathbb{R}^n \setminus B_1 \),

\[
|u(x)| \leq \left| u \left( \frac{x}{|x|} \right) \right| + \left| u(x) - u \left( \frac{x}{|x|} \right) \right| \leq M + M \left| x - \frac{x}{|x|} \right|
\]

\[
= M + M \left| \frac{x}{|x|} (|x| - 1) \right| = M + M \left| |x| - 1 \right| = M + M \left( |x| - 1 \right) = M |x|.
\]

Now, we consider the function \( \mathbb{R}^n \ni y \mapsto \frac{u(ry)}{r} =: u_r(y) \) and we observe that \(|u_r(x)| \leq M |x| \) for any \( x \in \mathbb{R}^n \setminus B_{1/r} \), due to \((6.2)\). Furthermore, the Lipschitz constant of \( u_r \) in \( x \in \mathbb{R}^n \setminus B_{1/r} \) is bounded...
by $M$, thanks to (1.4). From this and the Arzelà-Ascoli Theorem, up to a subsequence, we have that $u_r$ converges locally uniformly to some function $u_\infty$, with Lipschitz constant in $\mathbb{R}^n \setminus \{0\}$ bounded by $M$, and $E_\infty$ is a subgraph described by the function $u_\infty$. This proves (6.1).

Now, from (6.1) and Theorem 1, we infer that $E_\infty$ is a halfspace. This and the blow-down theory in (2.2) imply that $E$ is a halfspace, as desired. □

7. Proof of Theorem 5

Suppose that $0 \in \partial E$ and let $E_0$ be the blow-up cone of $E$. Since $E$ is a subgraph, from Lemma 16.3 in [24], we know that $E_0$ is a quasi-subgraph, i.e. there exists $u_0 : \mathbb{R}^n \to \mathbb{R} \cup \{-\infty\} \cup \{+\infty\}$ such that

$$E_0 = \{x_{n+1} < u(x_1, \ldots, x_n)\}.$$

We also stress that the only possible singular point for $E_0$ is the origin, thanks to Corollary 9 and our assumption on the cones in one dimension less.

Now, we distinguish two cases: either $E_0$ is a subgraph, or not. In the first case, since there are no singular cones in one dimension less, then $E_0$ satisfies the assumption of Theorem 1 and consequently must be a halfspace. Consequently, by (2.1), it follows that $E$ is $C^\infty$ near the origin.

Viceversa, if $E_0$ is not a subgraph, there exists $\tau > 0$ such that $\partial E_0$ and $\partial E_0 + \tau e_n$ touch at some point, different than the origin. Hence, we can apply the strong maximum principle at such touching point and conclude that

$$(7.1) \quad E_0 = \tilde{E} \times \mathbb{R},$$

where $\tilde{E}$ is an $s$-minimal cone in one dimension less (see e.g. footnote 3 in [20] for the details on the maximum principle). By assumption, $\tilde{E}$ has to be a halfspace, which means that $E_0$ is a (vertical) halfspace. Once again, by the theory of blow-up cones in (2.1), it follows that $E$ is a $C^\infty$ near the origin (in vertical coordinates). □

Appendix A. Proof of (3.7)

We point out that, since $F$ is odd and (3.1) holds true, then for any $x \neq 0$ and $\vartheta \in B_\varrho(x)$, with $\varrho := \frac{1}{2} \min\{1, |x|\}$,

$$|F\left(\frac{u(x+\vartheta)-u(x)}{|\vartheta|}\right) + F\left(\frac{u(x-\vartheta)-u(x)}{|\vartheta|}\right)| \leq \frac{\text{const} \left|\frac{u(x+\vartheta)-u(x)}{|\vartheta|}\right|}{|\vartheta|^{n+s}} \left(\frac{\left|\frac{u(x+\vartheta)-u(x)}{|\vartheta|}\right|}{|\vartheta|^{n+s}} - \frac{\left|\frac{u(x-\vartheta)-u(x)}{|\vartheta|}\right|}{|\vartheta|^{n+s}}\right) \leq \frac{\text{const} \left|\frac{u(x+\vartheta)+u(x-\vartheta)-2u(x)}{|\vartheta|^{n+s+1}}\right|}{|\vartheta|^{n+s+1}},$$

which is locally integrable near the origin as a function of $\vartheta$. This computation shows (3.7). □

Appendix B. Proof of (3.8)

We observe that, for all $A, B, a, b \in \mathbb{R}$, since $F'$ is even, it holds that

$$(B.1) \quad |F'(A)B + F'(a)b| \leq |F'(A)(B+b)| + |(F'(A) - F'(a))b| \leq \text{const} \left(|B+b| + |A+a| |b|\right).$$

We take

$$A := \frac{u(x+\vartheta)-u(x)}{|\vartheta|}, \quad B := v(x+\vartheta) - v(x),$$

$$a := \frac{u(x-\vartheta)-u(x)}{|\vartheta|}, \quad b := v(x-\vartheta) - v(x).$$
Then, by (3.1), if \( \varrho := \frac{1}{2} \min \{1, |x| \} \) and \( \vartheta \in B_{\varrho}(x) \),
\[
|b| \leq \text{const} \, |\vartheta|,
\]
\[
|A + a| = \frac{|u(x + \vartheta) + u(x - \vartheta) - 2u(x)|}{|\vartheta|} \leq \text{const} \, |\vartheta|
\]
and
\[
|B + b| = |v(x + \vartheta) + v(x - \vartheta) - 2v(x)| \leq \text{const} \, |\vartheta|^2.
\]
As a result, for any \( \vartheta \in B_{\varrho} \subset \mathbb{R}^n \),
\[
F' \left( \frac{u(x + \vartheta) - u(x)}{|\vartheta|} \right) \left( v(x + \vartheta) - v(x) \right) + F' \left( \frac{u(x - \vartheta) - u(x)}{|\vartheta|} \right) \left( v(x - \vartheta) - v(x) \right) \leq \frac{\text{const} \, |\vartheta|^2}{|\vartheta|^{n+s+1}},
\]
which, as a function of \( \vartheta \), belongs to \( L^1(B_{\varrho}) \). These considerations give that the integral in (3.8) is well-defined.

Furthermore, for all \( h \in \mathbb{R} \) with \( |h| \) small, if \( \vartheta \in B_{\varrho} \),
\[
u(x + he_j \pm \vartheta) - u(x + he_j) = u(x \pm \vartheta) - u(x) + h \int_0^1 v(x + the_j \pm \vartheta) - v(x + the_j) \, dt
\]
and therefore
\[
F \left( \frac{u(x + he_j \pm \vartheta) - u(x + he_j)}{|\vartheta|} \right) = F \left( \frac{u(x \pm \vartheta) - u(x)}{|\vartheta|} \right) + h \int_0^1 v(x + the_j \pm \vartheta) - v(x + the_j) \, dt
\]
\[
= \left( \int_0^1 F' \left( \frac{u(x \pm \vartheta) - u(x)}{|\vartheta|} \right) v(x + the_j \pm \vartheta) - v(x + the_j) \, dt \right) d\tau + \frac{h}{|\vartheta|} \int_0^1 v(x + the_j \pm \vartheta) - v(x + the_j) \, dt.
\]
Hence, we exploit (B.1) with
\[
A := \frac{u(x + \vartheta) - u(x)}{|\vartheta|} + \frac{\tau h}{|\vartheta|} \int_0^1 v(x + the_j + \vartheta) - v(x + the_j) \, dt
\]
\[
B := \frac{1}{|\vartheta|} \int_0^1 v(x + the_j + \vartheta) - v(x + the_j) \, dt
\]
\[
a := \frac{u(x - \vartheta) - u(x)}{|\vartheta|} + \frac{\tau h}{|\vartheta|} \int_0^1 v(x + the_j - \vartheta) - v(x + the_j) \, dt
\]
and
\[
b := \frac{1}{|\vartheta|} \int_0^1 v(x + the_j - \vartheta) - v(x + the_j) \, dt.
\]
We remark that, in this case,
\[
|A + a| \leq \frac{|u(x + \vartheta) + u(x - \vartheta) - 2u(x)|}{|\vartheta|} + \frac{|h|}{|\vartheta|} \int_0^1 \left| v(x + the_j + \vartheta) + v(x + the_j - \vartheta) - 2v(x + the_j) \right| \, dt
\]
\[
\leq \text{const} \min \{1, |\vartheta|\}.
\]
Also,
\[
|b| \leq \text{const}
\]
and
\[ |B + b| \leq \frac{1}{|\vartheta|} \int_0^1 \left| v(x + \text{the}_j + \vartheta) + v(x + \text{the}_j - \vartheta) - 2v(x + \text{the}_j) \right| dt \]
\[ \leq \text{const min}\{1, |\vartheta|\}. \]

In this way, using (B.1), we find that if
\[ \mathcal{F}(x, \vartheta) := \frac{F\left(\frac{u(x+\vartheta)-u(x)}{|\vartheta|}\right) + F\left(\frac{u(x-\vartheta)-u(x)}{|\vartheta|}\right)}{|\vartheta|^{n+s}}, \]
then
\[
\begin{align*}
\left| \mathcal{F}(x + he_j, \vartheta) - \mathcal{F}(x, \vartheta) \right| & = \frac{1}{|h| |\vartheta|^{n+s}} \left[ \int_0^1 F' \left( \frac{u(x + \vartheta) - u(x)}{|\vartheta|} \right) + \frac{\tau h}{|\vartheta|} \int_0^1 v(x + \text{the}_j + \vartheta) - v(x + \text{the}_j) dt \right] d\tau \\
& \quad + \frac{h}{|\vartheta|} \int_0^1 v(x + \text{the}_j + \vartheta) - v(x + \text{the}_j) dt \\
& \quad + F' \left( \frac{u(x - \vartheta) - u(x)}{|\vartheta|} \right) + \frac{\tau h}{|\vartheta|} \int_0^1 v(x + \text{the}_j - \vartheta) - v(x + \text{the}_j) dt \\
& \quad \cdot \frac{h}{|\vartheta|} \int_0^1 v(x + \text{the}_j - \vartheta) - v(x + \text{the}_j) dt \\
& = \frac{1}{|\vartheta|^{n+s}} \left[ \int_0^1 F'(A)B - F'(a)b \right] d\tau \\
& \leq \int_0^1 \text{const} \left( |B + b| + |A + a| |b| \right) d\tau \\
& \leq \text{const min}\{1, |\vartheta|\}
\end{align*}
\]
and the latter function belongs to $L^1(\mathbb{R}^n)$. This says that we can make use of the Dominated Convergence Theorem and conclude that
\[
\lim_{h \to 0} \frac{\mathcal{F}[u](x + he_j) - \mathcal{F}[u](x + h)}{h} = \lim_{h \to 0} \frac{1}{h} \left[ \int_{\mathbb{R}^n} \frac{F\left(\frac{u(x+he_j+\vartheta)-u(x)}{|\vartheta|}\right) + F\left(\frac{u(x+he_j-\vartheta)-u(x)}{|\vartheta|}\right)}{|\vartheta|^{n+s}} - F\left(\frac{u(x+\vartheta)-u(x)}{|\vartheta|}\right) + F\left(\frac{u(x-\vartheta)-u(x)}{|\vartheta|}\right) d\vartheta \right]
\]
\[
= \lim_{h \to 0} \int_{\mathbb{R}^n} \frac{\mathcal{F}(x + he_j, \vartheta) - \mathcal{F}(x, \vartheta)}{h} d\vartheta
\]
\[
= \int_{\mathbb{R}^n} \lim_{h \to 0} \frac{\mathcal{F}(x + he_j, \vartheta) - \mathcal{F}(x, \vartheta)}{h} d\vartheta
\]
\[
= \int_{\mathbb{R}^n} \partial_{x_j} \mathcal{F}(x, \vartheta) d\vartheta
\]
\[
= \int_{\mathbb{R}^n} F' \left( \frac{u(x+\vartheta)-u(x)}{|\vartheta|} \right) \left( v(x + \vartheta) - v(x) \right) + F' \left( \frac{u(x-\vartheta)-u(x)}{|\vartheta|} \right) \left( v(x - \vartheta) - v(x) \right) d\vartheta.
\]
This establishes (3.8), as desired.
