Model categorical Koszul-Tate resolution for algebras over differential operators

Gennaro di Brino, Damjan Pištalo, and Norbert Poncin

Abstract

Derived \( \mathcal{D} \)-Geometry is considered as a convenient language for a coordinate-free investigation of nonlinear partial differential equations (up to symmetries). One of the first issues one meets in the functor of points approach to derived \( \mathcal{D} \)-Geometry, is the question of a model structure on the category \( \mathcal{C} \) of differential non-negatively graded quasi-coherent commutative algebras over the sheaf \( \mathcal{D} \) of differential operators of an appropriate underlying variety. In [BPP15a], we described a cofibrantly generated model structure on \( \mathcal{C} \) via the definition of its weak equivalences and its fibrations. In the present article – the second of a series of works on the Batalin-Vilkovisky-formalism – we characterize the class of cofibrations, give explicit functorial cofibration-fibration factorizations, as well as explicit functorial fibrant and cofibrant replacement functors. We then use the latter to build a model categorical Koszul-Tate resolution for \( \mathcal{D} \)-algebraic ‘on-shell function’ algebras.

Keywords: Differential operator, \( \mathcal{D} \)-module, commutative monoid, model category, relative Sullivan algebra, derived Geometry, functor of points, PDE, Koszul-Tate resolution

1 Introduction

The study of systems of nonlinear PDE-s and their symmetries, via the functor of points approach to spaces and varieties, leads to derived \( \mathcal{D} \)-stacks, i.e., roughly, locally representable sheaves \( \text{DG}_{+} \text{qcCAlg}(\mathcal{D}_{\mathcal{X}}) \to \text{SSet} \) valued in the category \( \text{SSet} \) of simplicial sets and defined on the category \( \text{DG}_{+} \text{qcCAlg}(\mathcal{D}_{\mathcal{X}}) \) of differential non-negatively graded commutative algebras – over the sheaf \( \mathcal{D}_{\mathcal{X}} \) of differential operators of a smooth affine scheme \( \mathcal{X} \), whose terms are quasi-coherent as modules over the function sheaf \( \mathcal{O}_{\mathcal{X}} \) of \( \mathcal{X} \). The sheaf condition appears a the fibrant object condition of a model structure on the category of the corresponding presheaves. This structure depends on the model structure of the source category, which is equivalent to the category \( \text{DGDA} \) of differential non-negatively graded commutative algebras over the total sections \( \mathcal{D} := \mathcal{D}_{\mathcal{X}}(\mathcal{X}) = \Gamma(\mathcal{X}, \mathcal{D}_{\mathcal{X}}) \) of \( \mathcal{D}_{\mathcal{X}} \). In [BPP15a], we defined and
studied a finitely generated model structure on $\text{DGDA}$. In the present paper, we complete its description: we characterize cofibrations as the retracts of the relative Sullivan $\mathcal{D}$-algebras. Further, we give explicit functorial ‘TrivCof – Fib’ and ‘Cof – TrivFib’ factorizations (as well as the corresponding functorial fibrant and cofibrant replacement functors). The latter are specific to the considered setting and are of course different from those provided, for arbitrary cofibrantly generated model categories, by the small object argument. Eventually, we review the $\mathcal{D}$-geometric counterpart $\mathcal{R}$ of an algebra of on-shell functions and apply our machinery to find a model categorical Koszul-Tate (KT) resolution of $\mathcal{R}$. This resolution is a cofibrant replacement of $\mathcal{R}$ in an appropriate coslice category of $\text{DGDA}$. In contrast with
- the classical KT resolution constructed in coordinates [Bar10], for any regular on-shell irreducible gauge theory (as the Tate extension of the local Koszul resolution of a regular surface), and
- the compatibility complex KT resolution built in coordinates [Ver02], under regularity and off-shell reducibility conditions (existence of a finite formally exact compatibility complex),

the mentioned $\mathcal{D}$-geometric KT resolution, obtained from the cofibrant replacement functor of $\text{DGDA}$, is functorial and exists without the preceding restrictive hypotheses.

In this series of papers, our final goal is to combine and generalize aspects of Vinogradov’s secondary calculus [Vin01], of the homotopical algebraic geometry (HAG) developed by Toën and Vezzosi [TV04, TV08], and the $\mathcal{D}$-geometry used by Beilinson and Drinfeld [BD04]. For Vinogradov, the fundamental category is roughly the homotopy category of the (coslice category under a fixed diffiety or $\mathcal{D}$-scheme [in particular, under a fixed affine $\mathcal{D}$-scheme or $\mathcal{D}$-algebra] of the) category $\text{DGDM}$ of differential graded $\mathcal{D}$-modules. In the present paper, we study the homotopy theory of ‘diffieties’ by describing a model structure on $\text{DGDA}$: we investigate the $\mathcal{D}$-analog of Rational Homotopy Theory. On the other hand, HAG deals with the category $\text{DGCA}$ of differential graded commutative algebras over a commutative ring. To study partial differential equations, we have to switch to the category of differential graded commutative algebras over the sheaf of noncommutative rings of differential operators of a scheme or variety. Eventually, in comparison with the frame considered by Beilinson and Drinfeld, we aim at dealing not only with $\mathcal{D}$-schemes, but also with (derived) $\mathcal{D}$-stacks. We expect this context to be the correct setting for a coordinate-free gauge reduction – see [PP16] and [BPP16] for first results.

Let us emphasize that the special behavior of the noncommutative ring $\mathcal{D}$ turns out to be a source of possibilities, as well as of problems. For instance, a differential graded commutative algebra (DGCA) $A$ over a field or a commutative ring $k$ is a differential graded $k$-module, endowed with a degree zero associative graded-commutative unital $k$-bilinear multiplication, for which the differential is a graded derivation. The extension of this concept to noncommutative rings $R$ is not really considered in the literature. Indeed, the former definition of a DGCA over $k$ is equivalent to saying that $A$ is a commutative monoid in the category of differential graded $k$-modules. However, for noncommutative rings $R$, the category of differential graded (left) $R$-modules is not symmetric monoidal and the notion of commutative monoid is meaning-
less. In the case \( R = \mathcal{D} \), we get differential graded (left) \( \mathcal{D} \)-modules and these are symmetric monoidal. But a commutative monoid is not exactly the noncommutative analog of a DGCA in the preceding sense: the multiplication is only \( \mathcal{O} \)-bilinear and, in addition, vector fields act on products as derivations. Further, although we largely avoid sheaves via the confinement to affine schemes – a necessary restriction, without which no projective model structure would exist on the relevant categories [Har97, Ex. III.6.2] –, sheaves and quasi-coherence do require a careful approach. Examples of more challenging aspects are the questions of flatness and projectivity of \( \mathcal{D} = \mathcal{D}_X(X) \) viewed as \( \mathcal{O} = \mathcal{O}_X(X) \)-module, the combination of ‘finite’ and ‘transfinite’ definitions and results, the functorial ‘TrivCof – Fib’ and ‘Cof – TrivFib’ factorizations...

Eventually, we hope that the present text and the one of [BPP15a] will be considered as self-contained, not only by researchers from different fields, like e.g., homotopical algebra, geometry, mathematical physics, but also by graduate students.

The paper is organized as follows:

**Contents**

1. **Introduction**

2. **Preliminaries**

In the following, we freely use notation, definitions, and the results of [BPP15a]. For the convenience of the reader, we nevertheless recall some concepts and propositions in the present
section. For explanations on \(D\)-modules, sheaves versus global sections, model categories, small objects, cofibrant generation, as well as on relative Sullivan algebras, we refer the reader to \([\text{BPP15a}, \text{Appendix}]\).

**Theorem 1.** For any unital ring \(R\), the category \(\text{Ch}_+(R)\) of non-negatively graded chain complexes of left \(R\)-modules is a finitely (and thus a cofibrantly) generated model category (in the sense of \([\text{GS06}]\) and in the sense of \([\text{Hov07}]\)), with

\[
I = \{i_k : S_{\bullet}^{k-1} \to D_{\bullet}^k, \ k \geq 0\}
\]
as its generating set of cofibrations and

\[
J = \{\zeta_k : 0 \to D_{\bullet}^k, \ k \geq 1\}
\]
as its generating set of trivial cofibrations. Here \(D_{\bullet}^k\) is the \(k\)-disc chain complex

\[
D_{\bullet}^k : \cdots \to 0 \to 0 \to (k) \to 0 \to \cdots \to 0,
\]
and \(S_{\bullet}^k\) is the \(k\)-sphere chain complex

\[
S_{\bullet}^k : \cdots \to 0 \to 0 \to (k) \to 0 \to \cdots \to 0,
\]
and \(i_k, \zeta_k\) are the canonical chain maps. The weak equivalences of this model structure are the chain maps that induce an isomorphism in homology, the cofibrations are the injective chain maps with degree-wise projective cokernel (projective object in \(\text{Mod}(R)\)), and the fibrations are the chain maps that are surjective in (strictly) positive degrees. Further, the trivial cofibrations are the injective chain maps \(i\) whose cokernel \(\text{coker}(i)\) is strongly projective as a chain complex (strongly projective object \(\text{coker}(i)\) in \(\text{Ch}_+(R)\), in the sense that, for any chain map \(c : \text{coker}(i) \to C\) and any chain map \(p : D \to C\), there is a chain map \(\ell : \text{coker}(i) \to D\) such that \(p \circ \ell = i\), if \(p\) is surjective in (strictly) positive degrees).

**Proposition 1.** If \(X\) is a smooth affine algebraic variety, its global section functor yields an equivalence of symmetric monoidal categories

\[
\Gamma(X, \bullet) : (\text{DG}_{+}\text{qcMod}(D_X), \otimes_{\mathcal{O}_X}, \mathcal{O}_X) \to (\text{DGDM}, \otimes_{\mathcal{O}}, \mathcal{O})
\]
between the category of differential non-negatively graded modules over the sheaf \(D_X\) of differential operators on \(X\), which are quasi-coherent as modules over the function sheaf \(\mathcal{O}_X\), and the category of differential non-negatively graded modules over the ring \(D = D_X(X)\) of global sections of \(D_X\). The tensor product is taken over the sheaf \(\mathcal{O}_X\) and over the algebra \(\mathcal{O} = \mathcal{O}_X(X)\), respectively.

**Proposition 2.** If \(X\) is a smooth affine algebraic variety, its global section functor induces an equivalence of categories

\[
\Gamma(X, \bullet) : \text{DG}_{+}\text{qcCAlg}(D_X) \to \text{DGDA}
\]
between the category of differential non-negatively graded \(\mathcal{O}_X\)-quasi-coherent commutative algebras over \(D_X\) and the category of differential non-negatively graded commutative algebras over \(D\).
Proposition 3. The graded symmetric tensor algebra functor $S$ and the forgetful functor $F$ provide an adjoint pair

$$S : \text{DGDM} \rightleftarrows \text{DGDA} : F$$

between the category $\text{DGDM}$ and the category $\text{DGDA}$.

Theorem 2. The category $\text{DGDA}$ of differential non-negatively graded commutative $D$-algebras is a finitely (and thus a cofibrantly) generated model category (in the sense of [GS06] and in the sense of [Hov07]), with $S(I) = \{S(\iota_k) : \iota_k \in I\}$ as its generating set of cofibrations and $S(J) = \{S(\zeta_k) : \zeta_k \in J\}$ as its generating set of trivial cofibrations. The weak equivalences are the $\text{DGDA}$-morphisms that induce an isomorphism in homology. The fibrations are the $\text{DGDA}$-morphisms that are surjective in all positive degrees $p > 0$.

Below, we will describe the cofibrations and functorial fibrant and cofibrant replacement functors.

The model structure on $\text{DGDA}$ is obtained by Quillen transfer of the model structure on $\text{DGDM} = \text{Ch}^+(D)$. However, since $D$-modules (resp., $D$-algebras) are actually sheaves of modules (resp., sheaves of algebras), the category of differential graded $D$-modules (resp., differential graded $D$-algebras) over $X$ is rather $\text{DGDA}$ with $S(\iota_k) = \{S(\iota_k) : \iota_k \in \iota\}$ as its generating set of cofibrations and $S(J) = \{S(\zeta_k) : \zeta_k \in \zeta\}$ as its generating set of trivial cofibrations. The weak equivalences are the $\text{DGDA}$-morphisms that induce an isomorphism in homology. The fibrations are the $\text{DGDA}$-morphisms that are surjective in all positive degrees $p > 0$.

3 Description of $\text{DGDA}$-cofibrations

3.1 Relative Sullivan $D$-algebras

We recall the definition of relative Sullivan $D$-algebras [BPPT].

If $(A, d_A) \in \text{DGDA}$ and if $(M, d_M) \in \text{DGDM}$, then $(A \otimes SM, d)$ is $\text{DGDA}$. The differential $d_S$ of $SM$ is canonically generated by $d_M$ and the differential $d$ of $A \otimes SM$ is given by

$$d = d_A \otimes \text{id} + \text{id} \otimes d_S .$$

(5)

If $V \in \text{GDM}$, we have $(V, 0) \in \text{DGDM}$ and $A \otimes SV \in \text{GDA}$. In the sequel, we equip this graded $D$-algebra with a differential $d$ that coincides with $d_A \otimes \text{id}$ on $A \otimes 1_D \simeq A$, but not with some differential $d_M \otimes d_S$ on $1_A \otimes SV \simeq SV$. To distinguish such a differential graded $D$-algebra from $(A \otimes SV, d)$ with differential (5), we denote it by $(A \boxtimes SV, d)$.

Definition 1. A relative Sullivan $D$-algebra (RSDA) is a $\text{DGDA}$-morphism

$$(A, d_A) \rightarrow (A \boxtimes SV, d)$$

that sends $a \in A$ to $a \otimes 1 \in A \boxtimes SV$. Here $V$ is a free non-negatively graded $D$-module, which admits a homogeneous basis $(g_\alpha)_{\alpha \in J}$ that is indexed by a well-ordered set $J$, and is such that

$$dg_\alpha \in A \boxtimes SV_{<\alpha} ,$$

(6)
for all $\alpha \in J$. In the last requirement, we set $V_{<\alpha} := \bigoplus_{\beta < \alpha} D \cdot g_\beta$. We refer to Property (7) by saying that $d$ is lowering. A RSDA with Property
\begin{equation}
\alpha \leq \beta \Rightarrow \deg g_\alpha \leq \deg g_\beta ,
\end{equation}
where $\deg g_\alpha$ is the degree of $g_\alpha$ (resp., with Property (8)); over $(A,d_A) = (\mathcal{O},0)$ is called a minimal RSDA (resp., a split RSDA; a Sullivan $D$-algebra (SDA)).

The next lemma allows to define non-split RSDA-s, as well as DGDA-morphisms from such an RSDA into another differential graded $D$-algebra.

Lemma 1. Let $(T,d_T) \in \text{DGDA}$, let $(g_j)_{j \in J}$ be a family of symbols of degree $n_j \in \mathbb{N}$, and let $V = \bigoplus_{j \in J} D \cdot g_j$ be the free non-negatively graded $D$-module with homogeneous basis $(g_j)_{j \in J}$.

(i) To endow the graded $D$-algebra $T \otimes SV$ with a differential graded $D$-algebra structure $d$, it suffices to define
\begin{equation}
dg_j \in T_{n_j-1} \cap d_T^{-1}\{0\},
\end{equation}
to extend $d$ as $D$-linear map to $V$, and to equip $T \otimes SV$ with the differential $d$ given, for any $t \in T_p$, $v_1 \in V_{n_1}$, ..., $v_k \in V_{n_k}$, by
\begin{equation}
d(t \circ v_1 \circ \ldots \circ v_k) = d_T(t) \otimes v_1 \circ \ldots \circ v_k + (-1)^p \sum_{\ell=1}^k (-1)^{n_\ell} \sum_{j \leq \ell} (t_d v_j) \otimes v_1 \circ \ldots \hat{v}_\ell \circ \ldots \otimes v_k ,
\end{equation}
where $*$ is the multiplication in $T$. If $J$ is a well-ordered set, the natural map
\begin{equation}
(T,d_T) \ni t \mapsto t \otimes 1_\mathcal{O} \in (T \boxtimes SV,d)
\end{equation}
is a RSDA.

(ii) Moreover, if $(B,d_B) \in \text{DGDA}$ and $p \in \text{DGDA}(T,B)$, it suffices – to define a morphism $q \in \text{DGDA}(T \boxtimes SV,B)$ (where the differential graded $D$-algebra $(T \boxtimes SV,d)$ is constructed as described in (i)) – to define
\begin{equation}
q(g_j) \in B_{n_j} \cap d_B^{-1}\{p d(g_j)\},
\end{equation}
to extend $q$ as $D$-linear map to $V$, and to define $q$ on $T \otimes SV$ by
\begin{equation}
q(t \circ v_1 \circ \ldots \circ v_k) = p(t) \ast q(v_1) \ast \ldots \ast q(v_k) ,
\end{equation}
where $\ast$ denotes the multiplication in $B$.

The reader might consider that the definition of $d(t \otimes f)$, $f \in \mathcal{O}$, is not an edge case of Definition (1); if so, it suffices to add the definition $d(t \otimes f) = d_T(t) \circ f$. Note also that Definition (1) is the only possible one. Indeed, denote the multiplication in $T \otimes SV$ (see Equation (13) in [BPP15a]) by $\circ$ and choose, to simplify, $k = 2$. Then, if $d$ is any differential that is compatible with the graded $D$-algebra structure of $T \otimes SV$, and coincides with $d_T(t) \otimes 1_\mathcal{O} \simeq d_T(t)$ on any $t \otimes 1_\mathcal{O} \simeq t \in T$ (since $(T,d_T) \to (T \boxtimes SV,d)$ must be a
Proof. We first consider a pushout diagram for \( \phi \) is uniquely defined by the \( \text{transfer} \) model structure on \( \text{DG} \) of the transferred model structure on \( \text{RSDA} \). Similarly, since \( (\text{DG}, \text{RSDA}) \) are important instances of minimal non-split \( \text{RSDA} \)-morphism and \( d(v) \otimes 1_\mathcal{O} \simeq d(v) \) on any \( 1_T \otimes v \simeq v \in V \) (since \( d(v) \in T \)), we have necessarily

\[
d(t \otimes v_1 \otimes v_2) =
\]

\[
d(t \otimes 1_\mathcal{O}) \circ (1_T \otimes v_1) \circ (1_T \otimes v_2) +
\]

\[
(-1)^p(t \otimes 1_\mathcal{O}) \circ d(1_T \otimes v_1) \circ (1_T \otimes v_2) +
\]

\[
(-1)^{p+n_1} (t \otimes 1_\mathcal{O}) \circ (1_T \otimes v_1) \circ d(1_T \otimes v_2) =
\]

\[
(d_T(t) \otimes 1_\mathcal{O}) \circ (1_T \otimes v_1) \circ (1_T \otimes v_2) +
\]

\[
(-1)^p(t \otimes 1_\mathcal{O}) \circ (d(v_1) \otimes 1_\mathcal{O}) \circ (1_T \otimes v_2) +
\]

\[
(-1)^{p+n_1} (t \otimes 1_\mathcal{O}) \circ (1_T \otimes v_1) \circ (d(v_2) \otimes 1_\mathcal{O}) =
\]

\[
d_T(t) \otimes v_1 \otimes v_2 + (-1)^p(t \circ d(v_1)) \otimes v_2 + (-1)^{p+n_2} (t \circ d(v_2)) \otimes v_1.
\]

An analogous remark holds for Definition (11).

Proof. It is easily checked that the RHS of Equation (11) is graded symmetric in its arguments \( v_i \) and \( \mathcal{O} \)-linear with respect to all arguments. Hence, the map \( d \) is a degree \(-1\) \( \mathcal{O} \)-linear map that is well-defined on \( T \otimes \mathcal{S} V \). To show that \( d \) endows \( T \otimes \mathcal{S} V \) with a differential graded \( \mathcal{D} \)-algebra structure, it remains to prove that \( d \) squares to 0, is \( \mathcal{D} \)-linear and is a graded derivation for \( \circ \). The last requirement follows immediately from the definition, for \( \mathcal{D} \)-linearity it suffices to prove linearity with respect to the action of vector fields – what is a straightforward verification –, whereas 2-nilpotency is a consequence of Condition (8). The proof of (ii) is similar.

We are now prepared to give an example of a minimal non-split \( \text{RSDA} \).

Example 1. Consider the generating cofibrations \( \iota_n : S^{n-1} \to D^n \), \( n \geq 1 \), and \( \iota_0 : 0 \to S^0 \) of the model structure of \( \text{DGGM} \). The pushouts of the induced generating cofibrations

\[
\psi_n = S(\iota_n) \quad \text{and} \quad \psi_0 = S(\iota_0)
\]

of the transferred model structure on \( \text{DGDA} \) are important instances of minimal non-split \( \text{RSDA} \)-s – see Figure 2 and Equations (12), (13), (14), (16), and (17).

Proof. We first consider a pushout diagram for \( \psi := \psi_n \), for \( n \geq 1 \) – see Figure 2 where \( (T, d_T) \in \text{DGDA} \) and where \( \phi : (S(S^{n-1}), 0) \to (T, d_T) \) is a \( \text{DGDA} \)-morphism.

In the following, the generator of \( S^{n-1} \) (resp., the generators of \( D^n \)) will be denoted by \( 1_{n-1} \) (resp., by \( 1_n \) and \( s^{-1} 1_n \), where \( s^{-1} \) is the desuspension operator).

Note that, since \( S(S^{n-1}) \) is the free \( \text{DGDA} \) over the \( \text{DGGM} \) \( S^{n-1} \), the \( \text{DGDA} \)-morphism \( \phi \) is uniquely defined by the \( \text{DGGM} \)-morphism \( \phi|_{S^{n-1}} : S^{n-1} \to \text{For}(T, d_T) \), where \( \text{For} \) is the forgetful functor. Similarly, since \( S^{n-1} \) is, as \( \text{GDM} \), free over its generator \( 1_{n-1} \), the restriction
\[
\begin{align*}
\mathcal{S}(S^{n-1}) & \xrightarrow{\phi} (T, d_T) \\
\psi & \\
\mathcal{S}(D^n) & 
\end{align*}
\]

Figure 1: Pushout diagram

\(\phi|_{S^{n-1}}\) is, as \(\mathcal{GD}M\)-morphism, completely defined by its value \(\phi(1_{n-1}) \in T_{n-1}\). The map \(\phi|_{S^{n-1}}\) is then a \(\mathcal{GD}M\)-morphism if and only if we choose

\[\kappa_{n-1} := \phi(1_{n-1}) \in \ker_{n-1} d_T.\]  \(12\)

We now define the pushout of \((\psi, \phi)\): see Figure 2. In the latter diagram, the differential

\[
\begin{align*}
\mathcal{S}(S^{n-1}) & \xrightarrow{\phi} (T, d_T) \\
\psi & \\
\mathcal{S}(D^n) & \xrightarrow{j} (T \boxtimes \mathcal{S}(S^n), d) \\
& \downarrow {i} \\
& 
\end{align*}
\]

Figure 2: Completed pushout diagram

d of the \(\mathcal{GDA} T \boxtimes \mathcal{S}(S^n)\) is defined as described in Lemma 1. Indeed, we deal here with the free non-negatively graded \(\mathcal{D}\)-module \(S^n = S^n = \mathcal{D} \cdot 1_n\) and set

\[d(1_n) := \kappa_{n-1} = \phi(1_{n-1}) \in \ker_{n-1} d_T.\]

Hence, if \(x_{\ell} \simeq x_{\ell} \cdot 1_n \in \mathcal{D} \cdot 1_n\), we get \(d(x_{\ell}) = x_{\ell} \cdot \kappa_{n-1}\), and, if \(t \in T_p\), we obtain

\[d(t \otimes x_1 \otimes \ldots \otimes x_k) =
\]

\[d_T(t) \otimes x_1 \otimes \ldots \otimes x_k + (-1)^p \sum_{\ell=1}^k (-1)^{n(t-1)}(t \ast (x_{\ell} \cdot \kappa_{n-1})) \otimes x_1 \otimes \ldots \hat{x}_\ell \ldots \otimes x_k,
\]  \(13\)

see Equation 11. Eventually the map

\[i : (T, d_T) \ni t \mapsto t \otimes 1_\mathcal{O} \in (T \boxtimes \mathcal{S}(S^n), d)
\]  \(14\)

is a (minimal and non-split) \(RSDA\).

Just as \(\phi\), the \(\mathcal{GDA}\)-morphism \(j\) is completely defined if we define it as \(\mathcal{GD}M\)-morphism on \(D^n\). The choices of \(j(1_n)\) and \(j(s^{-1}1_n)\) define \(j\) as \(\mathcal{GD}M\)-morphism. The commutation condition of \(j\) with the differentials reads

\[j(s^{-1}1_n) = d j(1_n):
\]  \(15\)
only \( j(\mathbb{I}_n) \) can be chosen freely in \((T \otimes S(S^n))_n\).

The diagram of Figure 2 is now fully described. To show that it commutes, observe that, since the involved maps \( \phi, i, \psi, \) and \( j \) are all \( \mathcal{DGDA} \)-morphisms, it suffices to check commutation for the arguments \( 1_\mathcal{O} \) and \( 1_{n-1} \). Only the second case is non-obvious; we get the condition

\[
d j(\mathbb{I}_n) = \kappa_{n-1} \otimes 1_\mathcal{O}.
\]

It is easily seen that the unique solution is

\[
j(\mathbb{I}_n) = 1_T \otimes 1_n \in (T \otimes S(S^n))_n.\tag{17}
\]

To prove that the commuting diagram of Figure 2 is the searched pushout, it now suffices to prove its universality. Therefore, take \((B, d_B) \in \mathcal{DGDA}\), as well as two \( \mathcal{DGDA} \)-morphisms \( i' : (T, d_T) \to (B, d_B) \) and \( j' : S(D^n) \to (B, d_B) \), such that \( j' \circ \psi = i' \circ \phi \), and show that there is a unique \( \mathcal{DGDA} \)-morphism \( \chi : (T \boxtimes S(S^n), d) \to (B, d_B) \), such that \( \chi \circ i = i' \) and \( \chi \circ j = j' \).

If \( \chi \) exists, we have necessarily

\[
\chi(t \otimes x_1 \otimes \ldots \otimes x_k) = \chi((t \otimes 1_\mathcal{O} \otimes 1_T \otimes x_1) \otimes \ldots \otimes 1_T \otimes x_k))
\]

\[
= \chi(i(t)) \ast \chi(1_T \otimes x_1) \ast \ldots \ast \chi(1_T \otimes x_k),\tag{18}
\]

where we used the same notation as above. Since any differential operator \( x_i \simeq x_i \cdot 1_n \) is generated by functions and vector fields, we get

\[
\chi(1_T \otimes x_i) = \chi(1_T \otimes x_i \cdot 1_n) = x_i \cdot \chi(1_T \otimes 1_n) = x_i \cdot \chi(j(\mathbb{I}_n)) = x_i \cdot j'(\mathbb{I}_n) = j'(x_i \cdot \mathbb{I}_n).\tag{19}
\]

When combining (18) and (19), we see that, if \( \chi \) exists, it is necessarily defined by

\[
\chi(t \otimes x_1 \otimes \ldots \otimes x_k) = i'(t) \ast j'(x_1 \cdot \mathbb{I}_n) \ast \ldots \ast j'(x_k \cdot \mathbb{I}_n).\tag{20}
\]

This solves the question of uniqueness.

We now convince ourselves that (20) defines a \( \mathcal{DGDA} \)-morphism \( \chi \) (let us mention explicitly that we set in particular \( \chi(t \otimes f) = f \cdot i'(t) \), if \( f \in \mathcal{O} \)). It is straightforwardly verified that \( \chi \) is a well-defined \( \mathcal{D} \)-linear map of degree 0 from \((T \boxtimes S(S^n))_n \) to \( B \), which respects the multiplications and the units. The interesting point is the chain map property of \( \chi \). Indeed, consider, to simplify, the argument \( t \otimes x \), what will disclose all relevant insights. Assume again that \( t \in T_p \) and \( x \in S^n \), and denote the differential of \( S(D^n) \), just as its restriction to \( D^n \), by \( s^{-1} \). It follows that

\[
d_B(\chi(t \otimes x)) = i'(d_T(t)) \ast j'(x \cdot \mathbb{I}_n) + (-1)^p i'(t) \ast j'(x \cdot s^{-1} \mathbb{I}_n).\]

Since \( \psi(1_{n-1}) = s^{-1} \mathbb{I}_n \) and \( j' \circ \psi = i' \circ \phi \), we obtain \( j'(s^{-1} \mathbb{I}_n) = i'(\phi(1_{n-1})) = i'(\kappa_{n-1}) \). Hence,

\[
d_B(\chi(t \otimes x)) = \chi(d_T(t) \otimes x) + (-1)^p i'(t) \ast i'(x \cdot \kappa_{n-1}) = \chi(d(t \otimes x)).
\]
As afore-mentioned, no new feature appears, if we replace $t \otimes x$ by a general argument.

As the conditions $\chi \circ i = i'$ and $\chi \circ j = j'$ are easily checked, this completes the proof of the statement that any pushout of any $\psi_n$, $n \geq 1$, is a minimal non-split RS\text{DA}.

The proof of the similar claim for $\psi_0$ is analogous and even simpler, and will not be detailed here.

Actually pushouts of $\psi_0$ are border cases of pushouts of the $\psi_n$-s, $n \geq 1$. In other words, to obtain a pushout of $\psi_0$, it suffices to set, in Figure 2 and in Equation (3.1), the degree $n$ to 0. Since we consider exclusively non-negatively graded complexes, we then get $S(S^{-1}) = S(0) = 0$, $S(D^0) = S(S^0)$, and $\kappa_{-1} = 0$.

### 3.2 \textsc{dgDA}-cofibrations

The following theorem characterizes the cofibrations of the cofibrantly generated model structure we constructed on \textsc{dgda}.

**Theorem 3.** The \textsc{dgDA}-cofibrations are exactly the retracts of the relative Sullivan \textsc{d}-algebras.

We first prove the following lemma.

**Lemma 2.** The \textsc{dgDA}-cofibrations are exactly the retracts of the transfinite compositions of pushouts of generating cofibrations

$$\psi_n : S(S^{n-1}) \to S(D^n), \quad n \geq 0.$$  

**Proof.** For concise additional information on model categories, we refer to [BPP15a, Appendices 8.4 and 8.6].

In any cofibrantly generated model category $\mathcal{M}$ with generating cofibrations $I$, every cofibration is a retract of an $I$-cell [Hov07, Proposition 2.1.18]. Moreover, in view of [Hov07, Lemma 2.1.10], we have

$$I\text{-cell} \subset LLP( RLP(I)) = \text{Cof}. \quad (21)$$

Since cofibrations are closed under retracts, it follows that any retract of an $I$-cell is a cofibration. Hence, cofibrations are exactly the retracts of the $I$-cells, i.e., the retracts of the transfinite compositions of pushouts of elements of $I$. For $\mathcal{M} = \text{dgda}$, we thus find that the cofibrations are the retracts of the transfinite compositions of pushouts of $\psi_n$-s, $n \geq 0$. \Halmos

The proof of Theorem 3 thus reduces to the proof of

**Theorem 4.** The transfinite compositions of pushouts of $\psi_n$-s, $n \geq 0$, are exactly the relative Sullivan \textsc{d}-algebras.

**Lemma 3.** For any $M, N \in \text{dgDM}$, we have

$$S(M \oplus N) \simeq SM \otimes SN$$

in \text{dgDA}.  

Proof. It suffices to remember that the binary coproduct in the category \( \text{DGDM} = \text{Ch}_+(\mathcal{D}) \) (resp., the category \( \text{DGDA} = \text{CMon}(\text{DGDM}) \)) of non-negatively graded chain complexes of \( \mathcal{D} \)-modules (resp., the category of commutative monoids in \( \text{DGDM} \)) is the direct sum (resp., the tensor product). The conclusion then follows from the facts that \( \mathcal{S} \) is the left adjoint of the forgetful functor and that any left adjoint commutes with colimits.

Any ordinal is zero, a successor ordinal, or a limit ordinal. We denote the class of all successor ordinals (resp., all limit ordinals) by \( \Omega_\alpha \) (resp., \( \Omega_\ell \)).

Proof of Theorem \([\text{11}]\) (i) Consider an ordinal \( \lambda \) and a \( \lambda \)-sequence in \( \text{DGDA} \), i.e., a colimit respecting functor \( X : \lambda \to \text{DGDA} \) (here \( \lambda \) is viewed as the category whose objects are the ordinals \( \alpha < \lambda \) and which contains a unique morphism \( \alpha \to \beta \) if and only if \( \alpha \leq \beta \)):

\[
X_0 \to X_1 \to \ldots \to X_n \to X_{n+1} \to \ldots X_{\omega} \to X_{\omega+1} \to \ldots \to X_\alpha \to X_{\alpha+1} \to \ldots
\]

We assume that, for any \( \alpha \) such that \( \alpha + 1 < \lambda \), the morphism \( X_\alpha \to X_{\alpha+1} \) is a pushout of some \( \psi_{n_\alpha+1} \) \( (n_{\alpha+1} \geq 0) \). Then the morphism \( X_0 \to \text{colim}_{\alpha<\lambda}X_\alpha \) is exactly what we call a transfinite composition of pushouts of \( \psi_{n} \)-s. Our task is to show that this morphism is a \( \text{RSDA} \).

We first compute the terms \( X_\alpha \), \( \alpha < \lambda \), of the \( \lambda \)-sequence, then we determine its colimit. For \( \alpha < \lambda \) (resp., for \( \alpha < \lambda, \alpha \in \Omega_\Lambda \)), we denote the differential graded \( \mathcal{D} \)-algebra \( X_\alpha \) (resp., the \( \mathcal{DGDA} \)-morphism \( X_{\alpha-1} \to X_\alpha \)) by \( (A_\alpha, d_\alpha) \) (resp., by \( X_{\alpha,\alpha-1} : (A_{\alpha-1}, d_{\alpha-1}) \to (A_\alpha, d_\alpha) \)). Since \( X_{\alpha,\alpha-1} \) is the pushout of some \( \psi_{n_\alpha} \) and some \( \mathcal{DGDA} \)-morphism \( \phi_\alpha \), its target algebra is of the form

\[
(A_\alpha, d_\alpha) = (A_{\alpha-1} \boxtimes \mathcal{S}(a_\alpha), d_\alpha)
\]

and \( X_{\alpha,\alpha-1} \) is the canonical inclusion

\[
X_{\alpha,\alpha-1} : (A_{\alpha-1}, d_{\alpha-1}) \ni a_{\alpha-1} \mapsto a_{\alpha-1} \otimes 1_\mathcal{O} \in (A_{\alpha-1} \boxtimes \mathcal{S}(a_\alpha), d_\alpha),
\]

see Example \([\text{11}]\). Here \( a_\alpha \) is the generator \( 1_{n_\alpha} \) of \( \mathcal{S}^{n_\alpha} \) and \( \langle a_\alpha \rangle \) is the free non-negatively graded \( \mathcal{D} \)-module \( \mathcal{S}^{n_\alpha} = \mathcal{D} \cdot a_\alpha \) concentrated in degree \( n_\alpha \); further, the differential

\[
d_\alpha \text{ is defined by } (3.1) \text{ from } d_{\alpha-1} \text{ and } \kappa_{n_\alpha-1} := \phi_\alpha (1_{n_\alpha-1}).
\]

In particular, \( A_1 = A_0 \boxtimes \mathcal{S}(a_1), d_1(a_1) = \kappa_{n_1-1} = \phi_1 (1_{n_1-1}) \in A_0, \) and \( X_{10} : A_0 \to A_1 \) is the inclusion.

Lemma 4. For any \( \alpha < \lambda \), we have

\[
A_\alpha \cong A_0 \otimes \mathcal{S}(a_\delta : \delta \leq \alpha, \delta \in \Omega_\alpha)
\]

as a graded \( \mathcal{D} \)-algebra, and

\[
d_\alpha(a_\delta) \in A_0 \otimes \mathcal{S}(a_\varepsilon : \varepsilon < \delta, \varepsilon \in \Omega_\delta),
\]
for all \( \delta \leq \alpha, \delta \in \Omega_s \). Moreover, for any \( \gamma \leq \beta \leq \alpha < \lambda \), we have

\[
A_\beta = A_\gamma \otimes S\langle a_\delta : \gamma < \delta \leq \beta, \delta \in \Omega_s \rangle
\]

and the \( \mathcal{DGDA} \)-morphism \( X_{\beta\gamma} \) is the natural inclusion

\[
X_{\beta\gamma} : (A_\gamma, d_\gamma) \ni a_\gamma \mapsto a_\gamma \otimes 1_\Omega \in (A_\beta, d_\beta).
\]  

Since the latter statement holds in particular for \( \gamma = 0 \) and \( \beta = \alpha \), the \( \mathcal{DGDA} \)-inclusion \( X_{\alpha_0} : (A_0,d_0) \rightarrow (A_\alpha, d_\alpha) \) is a \( \text{RSDA} \) (for the natural ordering of \( \{a_\delta : \delta \leq \alpha, \delta \in \Omega_s \} \)).

**Proof of Lemma 4.** To prove that this claim (i.e., Equations (25) – (27)) is valid for all ordinals that are smaller than \( \lambda \), we use a transfinite induction. Since the assertion obviously holds for \( \alpha = 1 \), it suffices to prove these properties for \( \alpha < \lambda \), assuming that they are true for all \( \beta < \alpha \). We distinguish (as usually in transfinite induction) the cases \( \alpha \in \Omega_s \) and \( \alpha \in \Omega_\ell \).

If \( \alpha \in \Omega_s \), it follows from Equation (22), from the induction assumption, and from Lemma 3 that

\[
A_\alpha = A_{\alpha-1} \otimes S(a_\alpha) \simeq A_0 \otimes S\langle a_\delta : \delta \leq \alpha, \delta \in \Omega_s \rangle,
\]

as graded \( \mathcal{D} \)-algebra. Further, in view of Equation (24) and the induction hypothesis, we get

\[
d_\alpha(a_\alpha) = \phi_\alpha(1_{\alpha-1}) \in A_{\alpha-1} = A_0 \otimes S\langle a_\delta : \delta < \alpha, \delta \in \Omega_s \rangle,
\]

and, for \( \delta \leq \alpha - 1, \delta \in \Omega_s \),

\[
d_\alpha(a_\delta) = d_{\alpha-1}(a_\delta) \in A_0 \otimes S\langle a_\gamma : \gamma < \delta, \gamma \in \Omega_s \rangle.
\]

Finally, as concerns \( X_{\beta\gamma} \), the unique case to check is \( \gamma \leq \alpha - 1 \) and \( \beta = \alpha \). The \( \mathcal{DGDA} \)-map \( X_{\alpha-1,\gamma} \) is an inclusion

\[
X_{\alpha-1,\gamma} : A_\gamma \ni a_\gamma \mapsto a_\gamma \otimes 1_\Omega \in A_{\alpha-1}
\]

(by induction), and so is the \( \mathcal{DGDA} \)-map

\[
X_{\alpha,\alpha-1} : A_{\alpha-1} \ni a_{\alpha-1} \mapsto a_{\alpha-1} \otimes 1_\Omega \in A_\alpha
\]

(in view of (23)). The composite \( X_{\alpha\gamma} \) is thus a \( \mathcal{DGDA} \)-inclusion as well.

In the case \( \alpha \in \Omega_\ell \), i.e., \( \alpha = \text{colim}_{\beta<\alpha} \beta \), we obtain \( (A_\alpha, d_\alpha) = \text{colim}_{\beta<\alpha}(A_\beta, d_\beta) \) in \( \mathcal{DGDA} \), since \( \mathcal{X} \) is a colimit respecting functor. The index set \( \alpha \) is well-ordered, hence, it is a directed poset. Moreover, for any \( \delta \leq \gamma \leq \beta < \alpha \), the \( \mathcal{DGDA} \)-maps \( X_{\beta\gamma}, X_{\gamma\delta}, \) and \( X_{\beta\gamma} \) satisfy \( X_{\beta\gamma} = X_{\beta\gamma} \circ X_{\gamma\delta} \). It follows that the family \( (A_\beta, d_\beta)_{\beta<\alpha} \), together with the family \( X_{\beta\gamma}, \gamma \leq \beta < \alpha \), is a direct system in \( \mathcal{DGDA} \), whose morphisms are, in view of the induction assumption, natural inclusions

\[
X_{\beta\gamma} : A_\gamma \ni a_\gamma \mapsto a_\gamma \otimes 1_\Omega \in A_\beta.
\]

The colimit \( (A_\alpha, d_\alpha) = \text{colim}_{\beta<\alpha}(A_\beta, d_\beta) \) is thus a direct limit. We proved in [BPP15a] that a direct limit in \( \mathcal{DGDA} \) coincides with the corresponding direct limit in \( \mathcal{DGDA} \), or even in \( \text{Set} \).
(which is then naturally endowed with a differential graded \( D \)-algebra structure). As a set, the direct limit \( (A_\alpha, d_\alpha) = \text{colim}_{\beta < \alpha} (A_\beta, d_\beta) \) is given by

\[
A_\alpha = \bigsqcup_{\beta < \alpha} A_\beta / \sim ,
\]

where \( \sim \) means that we identify \( a_\gamma, \gamma \leq \beta \), with

\[
a_\gamma \sim X_{\beta \gamma}(a_\gamma) = a_\gamma \otimes 1_O ,
\]
i.e., that we identify \( A_\gamma \) with

\[
A_\gamma \sim A_\gamma \otimes O \subset A_\beta .
\]

It follows that

\[
A_\alpha = \bigsqcup_{\beta < \alpha} A_\beta = A_0 \otimes S(a_{\delta} : \delta < \alpha, \delta \in O_s) = A_0 \otimes S(a_{\delta} : \delta \leq \alpha, \delta \in O_s) .
\]

As just mentioned, this set \( A_\alpha \) can naturally be endowed with a differential graded \( D \)-algebra structure. For instance, since, in view of what has been said, all \( \sim \)-classes consist of a single element, and since any \( a_\alpha \in A_\alpha \) belongs to some \( A_\beta, \beta < \alpha \), the differential \( d_\alpha \) is defined by

\[
d_\alpha(a_\alpha) = d_\beta(a_\alpha) .
\]

In particular, any generator \( a_{\delta}, \delta \leq \alpha, \delta \in O_s \), belongs to \( A_{\delta} \). Hence, by definition of \( d_\alpha \) and in view of the induction assumption, we get

\[
d_\alpha(a_{\delta}) = d_{\delta}(a_{\delta}) \in A_0 \otimes S(a_{\varepsilon} : \varepsilon < \delta, \varepsilon \in O_s) .
\]

Eventually, since \( X \) is colimit respecting, not only \( A_\alpha = \text{colim}_{\beta < \alpha} A_\beta \) but, furthermore, for any \( \gamma < \alpha \), the \( \text{DGDA} \)-morphism \( X_{\alpha \gamma} : A_\gamma \rightarrow A_\alpha \) is the map \( X_{\alpha \gamma} : A_\gamma \rightarrow \bigcup_{\beta < \alpha} A_\beta \), i.e., the canonical inclusion.

We now come back to the proof of Part (i) of Theorem 4, i.e., we now explain why the morphism \( i : (A_0, d_0) \rightarrow C \), where \( C = \text{colim}_{\alpha \leq \lambda} (A_\alpha, d_\alpha) \) and where \( i \) is the first of the morphisms that are part of the colimit construction, is a \( \text{RSDA} \) – see above. If \( \lambda \in O_s \), the colimit \( C \) coincides with \( (A_{\lambda-1}, d_{\lambda-1}) \) and \( i = X_{\lambda-1,0} \). Hence, the morphism \( i \) is a \( \text{RSDA} \) in view of Lemma 4. If \( \lambda \in O_\ell \), the colimit \( C = \text{colim}_{\alpha \leq \lambda}(A_\alpha, d_\alpha) \) is, like above, the direct limit of the direct \( \text{DGDA} \)-system \( (X_\alpha = (A_\alpha, d_\alpha), X_{\alpha \beta}) \) indexed by the directed poset \( \lambda \), whose morphisms \( X_{\alpha \beta} \) are, in view of Lemma 4 canonical inclusions. Hence, \( C \) is again an ordinary union:

\[
C = \bigcup_{\alpha < \lambda} A_\alpha = A_0 \otimes S(a_{\delta} : \delta < \lambda, \delta \in O_s) ,
\]

where the last equality is due to Lemma 4. We define the differential \( d_C \) on \( C \) exactly as we defined the differential \( d_\alpha \) on the direct limit in the proof of Lemma 4. It is then straightforwardly checked that \( i \) is a \( \text{RSDA} \).

(ii) We still have to show that any \( \text{RSDA} \) \( (A_0, d_0) \rightarrow (A_0 \boxtimes SV, d) \) can be constructed as a transfinite composition of pushouts of generating cofibrations \( \psi_n, n \geq 0 \). Let \( (a_j)_{j \in J} \) be the
basis of the free non-negatively graded $D$-module $V$. Since $J$ is a well-ordered set, it is order-isomorphic to a unique ordinal $\mu = \{0, 1, \ldots, n, \omega, \omega + 1, \ldots\}$, whose elements can thus be utilized to label the basis vectors. However, we prefer using the following order-respecting relabelling of these vectors:

$$a_0 \leadsto a_1, a_1 \leadsto a_2, \ldots, a_n \leadsto a_{n+1}, \ldots, a_\omega \leadsto a_{\omega+1}, a_{\omega+1} \leadsto a_{\omega+2}, \ldots$$

In other words, the basis vectors of $V$ can be labelled by the successor ordinals that are strictly smaller than $\lambda := \mu + 1$ (this is true, whether $\mu \in \mathcal{D}_s$, or $\mu \in \mathcal{D}_t$):

$$V = \bigoplus_{\delta < \lambda, \delta \in \mathcal{D}_s} D \cdot a_\delta.$$

For any $\alpha < \lambda$, we now set

$$(A_\alpha, d_\alpha) := (A_0 \boxtimes S\langle a_\delta : \delta \leq \alpha, \delta \in \mathcal{D}_s, d|_{A_\alpha} \rangle).$$

It is clear that $A_\alpha$ is a graded $D$-subalgebra of $A_0 \boxtimes SV$. Since $A_\alpha$ is generated, as an algebra, by the elements of the types $a_0 \otimes 1_\mathcal{O}$ and $D \cdot (1_{A_\alpha} \otimes a_\delta)$, $D \in D$, $\delta \leq \alpha$, $\delta \in \mathcal{D}_s$, and since

$$d(a_0 \otimes 1_\mathcal{O}) = d_0(a_0) \otimes 1_\mathcal{O} \in A_\alpha$$

and

$$d(D \cdot (1_{A_\alpha} \otimes a_\delta)) \in A_0 \otimes S\langle a_\varepsilon : \varepsilon < \delta, \varepsilon \in \mathcal{D}_s \rangle \subset A_\alpha,$$

the derivation $d$ stabilizes $A_\alpha$. Hence, $(A_\alpha, d_\alpha) = (A_\alpha, d|_{A_\alpha})$ is actually a differential graded $D$-subalgebra of $(A_0 \boxtimes SV, d)$.

If $\beta \leq \alpha < \lambda$, the algebra $(A_\beta, d|_{A_\beta})$ is a differential graded $D$-subalgebra of $(A_\alpha, d|_{A_\alpha})$, so that the canonical inclusion $i_{\alpha \beta} : (A_\beta, d_\beta) \rightarrow (A_\alpha, d_\alpha)$ is a $\mathbf{DGDA}$-morphism. In view of the techniques used in (i), it is obvious that the functor $X = (A_-, d_-) : \lambda \rightarrow \mathbf{DGDA}$ respects colimits, and that the colimit of the whole $\lambda$-sequence (remember that $\lambda = \mu + 1 \in \mathcal{D}_s$) is the algebra $(A_\mu, d_\mu) = (A_0 \boxtimes SV, d)$, i.e., the original algebra.

The $\mathbf{RSPA}$ $(A_0, d_0) \rightarrow (A_0 \boxtimes SV, d)$ has thus been built as transfinite composition of canonical $\mathbf{DGDA}$-inclusions $i : (A_\alpha, d_\alpha) \rightarrow (A_{\alpha+1}, d_{\alpha+1})$, $\alpha + 1 < \lambda$. Recall that

$$A_{\alpha+1} = A_\alpha \otimes S\langle a_{\alpha+1} \rangle \simeq A_\alpha \otimes S(S^n),$$

if we set $n := \deg(a_{\alpha+1})$. It suffices to show that $i$ is a pushout of $\psi_\alpha$, see Figure 3. We will detail the case $n \geq 1$. Since all the differentials are restrictions of $d$, we have $\kappa_{n-1} := d_{\alpha+1}(a_{\alpha+1}) \in A_\alpha \cap \ker_\alpha d_\alpha$, and $\phi(1_{\alpha-1}) := \kappa_{n-1}$ defines a $\mathbf{DGDA}$-morphism $\phi$, see Example 1. When using the construction described in Example 1 we get the pushout $i : (A_\alpha, d_\alpha) \rightarrow (A_\alpha \boxtimes S(S^n), \bar{\partial})$ of the morphisms $\psi_\alpha$ and $\phi$. Here $i$ is the usual canonical inclusion and $\bar{\partial}$ is the differential defined by Equation (5.1). It thus suffices to check that $\bar{\partial} = d_{\alpha+1}$. Let $a_\alpha \in A_\alpha^p$ and let $x_1 \simeq x_1 \cdot a_{\alpha+1}, \ldots, x_k \simeq x_k \cdot a_{\alpha+1} \in D \cdot a_{\alpha+1} = S^n$. Assume, to simplify, that $k = 2$: the
4 Explicit functorial cofibration – fibration decompositions

In [BPP15a, Theorem 4], we proved that any DGDA-morphism \( \phi : A \to B \) admits a functorial factorization

\[
A \xrightarrow{i} A \otimes SU \xrightarrow{p} B ,
\]

where \( p \) is a fibration and \( i \) is a weak equivalence, as well as a split minimal RSDA. In view of Theorem 3 of the present paper, the morphism \( i \) is thus a cofibration, with the result that we actually constructed a natural decomposition \( \phi = p \circ i \) of an arbitrary DGDA-morphism \( \phi \) into \( i \in \text{TrivCof} \) and \( p \in \text{Fib} \). The description of this factorization is summarized below, in Theorem 5 which provides essentially an explicit natural ‘Cof – TrivFib’ decomposition

\[
A \xrightarrow{i'} A \otimes SU' \xrightarrow{p'} B .
\]
Since the model category $\text{DGDA}$ is cofibrantly generated with generating cofibrations (resp., trivial cofibrations) $S(I)$ (resp., $S(J)$), it admits as well functorial factorizations ‘TrivCof – Fib’ and ‘Cof – TrivFib’ given by the small object argument (SOA). The latter general technique factors a morphism $\phi : A \to B$ into morphisms

$$A \xrightarrow{i} C \xrightarrow{p} B \quad (31)$$

that are obtained as the colimit of a sequence

$$A \xrightarrow{i_n} C_n \xrightarrow{p_n} B,$$

in a way such that $p \in \text{RLP}(S(J)) = \text{Fib}$ (resp., $p \in \text{RLP}(S(I)) = \text{TrivFib}$). The idea is that, in view of the smallness of the sources in $S$ (resp., $S(J)$), each commutative square with right down arrow $p : C \to B$ that must admit a lift, factors through a commutative square with right down arrow $p_n : C_n \to B$, and that it therefore suffices to construct $C_{n+1}$ in a way such that ‘it contains the required lift’. More details can be found in Appendix 6.1.

The decompositions (29) and (30) are $\text{DGDA}$-specific and different from the general SOA-factorizations (31). Further, they implement less abstract, in some sense Koszul-Tate type, functorial fibrant and cofibrant resolution functors.

Before stating the afore-mentioned Theorem 5, we sketch the construction of the factorization (30). To simplify, we denote algebras of the type $\text{Cof} – \text{TrivFib}$ and ‘trivial cofibrations) $S$.

The decompositions (29) and (30) are $\text{DGDA}$-specific and different from the general SOA-factorizations (31). Further, they implement less abstract, in some sense Koszul-Tate type, functorial fibrant and cofibrant resolution functors.

Before stating the afore-mentioned Theorem 5, we sketch the construction of the factorization (30). To simplify, we denote algebras of the type $A \otimes \text{SV}_k$ by $R_{V_k}$, or simply $R_k$.

We start from the ‘small’ ‘Cof – Fib’ decomposition (29) of a $\text{DGDA}$-morphism $A \xrightarrow{\phi} B$, i.e., from the factorization $A \xrightarrow{i} R_U \xrightarrow{p} B$, see [BPP15a, Section 7.7]. To find a substitute $q$ for $p$, which is a trivial fibration, we mimic an idea used in the construction of the Koszul-Tate resolution: we add generators to improve homological properties.

Note first that $H(p)$ is surjective if, for any homology class $[\beta_n] \in H_n(B)$, there is a class $[\beta_n] \in H_n(R_U)$, such that $[p \rho_n] = [\beta_n]$. Hence, consider all the homology classes $[\beta_n]$, $n \geq 0$, of $B$, choose in each class a representative $\hat{\beta}_n \simeq [\beta_n]$, and add generators $I_{\hat{\beta}_n}$ to those of $U$. It then suffices to extend the differential $d_1$ (resp., the fibration $p$) defined on $R_U = A \otimes SU$, so that the differential of $I_{\hat{\beta}_n}$ vanishes (resp., so that the projection of $I_{\hat{\beta}_n}$ coincides with $\hat{\beta}_n$) ($\triangleright_1$ – this triangle is just a mark that allows us to retrieve this place later on). To get a functorial ‘Cof – TrivFib’ factorization, we do not add a new generator $I_{\beta_n}$, for each homology class $\hat{\beta}_n \simeq [\beta_n] \in H_n(B)$, $n \geq 0$, but we add a new generator $I_{\beta_n}$, for each cycle $\beta_n \in \ker d_B$, $n \geq 0$. Let us implement this idea in a rigorous manner. Assign the degree $n$ to $I_{\beta_n}$ and set

$$V_0 := U \oplus G_0 := U \oplus \langle I_{\hat{\beta}_n} : \beta_n \in \ker d_B, n \geq 0 \rangle =$$

$$\langle s^{-1}I_{b_n}, I_{b_n}, I_{\hat{\beta}_n} : b_n \in B_n, n > 0, \beta_n \in \ker d_B, n \geq 0 \rangle. \quad (32)$$

Set now

$$\delta_{V_0}(s^{-1}I_{b_n}) = d_1(s^{-1}I_{b_n}) = 0, \quad \delta_{V_0}I_{b_n} = d_1I_{b_n} = s^{-1}I_{b_n}, \quad \delta_{V_0}I_{\hat{\beta}_n} = 0, \quad (33)$$
Model categorical Koszul-Tate resolution

thus defining, in view of [BPP15a, Lemma 1], a differential graded \( \mathcal{D} \)-module structure on \( V_0 \).

It follows that \( (SV_0, \delta_{V_0}) \in \text{DGDA} \) and that

\[
(R_0, \delta_0) := (A \otimes SV_0, d_A \otimes \text{id} + \text{id} \otimes \delta_{V_0}) \in \text{DGDA} .
\] (34)

Similarly, we set

\[
q_{V_0}(s^{-1}1_{b_n}) = p(s^{-1}1_{b_n}) = \varepsilon(s^{-1}1_{b_n}) = d_B b_n, \quad q_{V_0}1_{b_n} = p1_{b_n} = \varepsilon1_{b_n} = b_n, \quad q_{V_0}1_{\beta_n} = \beta_n .
\] (35)

We thus obtain [BPP15a, Lemma 2] a morphism \( q_{V_0} \in \text{DGDA}(V_0, B) \) – which uniquely extends to a morphism \( q_{V_0} \in \text{DGDA}(SV_0, B) \). Finally,

\[
q_0 = \mu_B \circ (\phi \otimes q_{V_0}) \in \text{DGDA}(R_0, B) ,
\] (36)

where \( \mu_B \) denotes the multiplication in \( B \). Let us emphasize that \( R_U = A \otimes SU \) is a direct summand of \( R_0 = A \otimes SV_0 \), and that \( \delta_0 \) and \( q_0 \) just extend the corresponding morphisms on \( R_U: \delta_0|_{R_U} = d_1 \) and \( q_0|_{R_U} = p \).

So far we ensured that \( H(q_0) : H(R_0) \to H(B) \) is surjective; however, it must be injective as well, i.e., for any \( \sigma_n \in \text{ker} \delta_0, n \geq 0 \), such that \( H(q_0)[\sigma_n] = 0 \), i.e., such that \( q_0\sigma_n \in \text{im} d_B \), there should exist \( \sigma_{n+1} \in R_0 \) such that

\[
\sigma_n = \delta_0\sigma_{n+1} .
\] (37)

We denote by \( B_0 \) the set of \( \delta_0 \)-cycles that are sent to \( d_B \)-boundaries by \( q_0 \):

\[
B_0 = \{ \sigma_n \in \text{ker} \delta_0 : q_0\sigma_n \in \text{im} d_B, n \geq 0 \} .
\]

In principle it now suffices to add, to the generators of \( V_0 \), generators \( 1_{\sigma_n} \) of degree \( n+1 \), \( \sigma_n \in B_0 \), and to extend the differential \( \delta_0 \) on \( R_0 \) so that the differential of \( 1_{\sigma_n} \) coincides with \( \sigma_n (\geq 2) \). However, it turns out that to obtain a *functorial* ‘Cof – TrivFib’ decomposition, we must add a new generator \( 1_{\sigma_n, b_{n+1}} \) of degree \( n+1 \), for each pair \( (\sigma_n, b_{n+1}) \) such that \( \sigma_n \in \text{ker} \delta_0 \) and \( q_0\sigma_n = d_B b_{n+1} : \) we set

\[
B_0 = \{ (\sigma_n, b_{n+1}) : \sigma_n \in \text{ker} \delta_0, b_{n+1} \in d_B^{-1}\{q_0\sigma_n\}, n \geq 0 \} .
\] (38)

and

\[
V_1 := V_0 \oplus G_1 := V_0 \oplus \langle 1_{\sigma_n, b_{n+1}} : (\sigma_n, b_{n+1}) \in B_0 \rangle .
\] (39)

To endow the graded \( \mathcal{D} \)-algebra

\[
R_1 := A \otimes SV_1 \simeq R_0 \otimes SG_1
\] (40)

with a differential graded \( \mathcal{D} \)-algebra structure \( \delta_1 \), we apply Lemma 4 (of the present paper), with

\[
\delta_1(1_{\sigma_n, b_{n+1}}) = \sigma_n \in (R_0)_n \cap \text{ker} \delta_0 ,
\] (41)
Lemma 1, as well as on equations of the same type as (41) and (42). The definition of the differentials δ of canonical inclusions of differential graded DG to

 together with a sequence of δ definitions of the differentials δ of canonical inclusions of differential graded DG to

 the generators and from Equation (11) in Lemma 1.

Eventually, starting from \((R_U, d_1) \in \text{DGDA} \) and \(p \in \text{DGDA}(R_U, B)\), we end up − when trying to make \(H(p)\) bijective − with \((R_1, \delta_1) \in \text{DGDA} \) and \(q_1 \in \text{DGDA}(R_1, B)\)− so that now \(H(q_1) : H(R_1) \to H(B)\) must be bijective. Since \((R_1, \delta_1)\) extends \((R_0, \delta_0)\) and \(H(q_0) : H(R_0) \to H(B)\) is surjective, it is easily checked that this property holds a fortiori for \(H(q_1)\). However, when working with \(R_1 \supset R_0\), the ‘critical set’ \(\mathcal{B}_1 \supset \mathcal{B}_0\) increases, so that we must add new generators \(\mathcal{I}^2_{\sigma_n}, \sigma_n \in \mathcal{B}_1 \setminus \mathcal{B}_0\), where

\[
\mathcal{B}_1 = \{ \sigma_n \in \ker \delta_1 : q_1 \sigma_n \in \im d_B, n \geq 0 \} \quad (\triangleright_3)
\]

To build a functorial factorization, we consider not only the ‘critical set’

\[
\mathfrak{B}_1 = \{ (\sigma_n, b_{n+1}) : \sigma_n \in \ker \delta_1, b_{n+1} \in d_B^{-1} \{ q_1 \sigma_n \}, n \geq 0 \}, \quad (43)
\]

but also the module of new generators

\[
G_2 = \{ (\mathcal{I}^2_{\sigma_n, b_{n+1}} : (\sigma_n, b_{n+1}) \in \mathfrak{B}_1) \}, \quad (44)
\]

indexed, not by \(\mathfrak{B}_1 \setminus \mathfrak{B}_0\), but by \(\mathfrak{B}_1\). Hence an iteration of the procedure (38) - (42) and the definition of a sequence

\[
(R_0, \delta_0) \to (R_1, \delta_1) \to (R_2, \delta_2) \to \ldots \to (R_{k-1}, \delta_{k-1}) \to (R_k, \delta_k) \to \ldots
\]

of canonical inclusions of differential graded D-algebras \((R_k, \delta_k)\), \(R_k = A \otimes SV_k, \delta_k|_{R_{k-1}} = \delta_{k-1}\), together with a sequence of DGDA-morphisms \(q_k : R_k \to B\), such that \(q_k|_{R_{k-1}} = q_{k-1}\). The definitions of the differentials \(\delta_k\) and the morphisms \(q_k\) are obtained inductively, and are based on Lemma 1 as well as on equations of the same type as (11) and (42).

The direct limit of this sequence is a differential graded D-algebra \((R_V, d_2) = (A \otimes SV, d_2)\), together with a morphism \(q : A \otimes SV \to B\).

As a set, the colimit of the considered system of canonically included algebras \((R_k, \delta_k)\), is just the union of the sets \(R_k\), see Equation (23). We proved above that this set-theoretical inductive limit can be endowed in the standard manner with a differential graded D-algebra structure and that the resulting algebra is the direct limit in DGDA. One thus obtains in particular that \(d_2|_{R_k} = \delta_k\).

Finally, the morphism \(q : R_V \to B\) comes from the universality property of the colimit and it allows to factor the morphisms \(q_k : R_k \to B\) through \(R_V\). We have: \(q|_{R_k} = q_k\).

We will show that this morphism \(A \otimes SV \xrightarrow{\phi} B\) really leads to a ‘Cof – TrivFib’ decomposition \(A \xrightarrow{j} A \otimes SV \xrightarrow{\delta} B\) of \(A \xrightarrow{\phi} B\).
Theorem 5. In $\text{DGDA}$, a functorial ‘TrivCof – Fib’ factorization $(i,p)$ and a functorial ‘Cof – TrivFib’ factorization $(j,q)$ of an arbitrary morphism 
\[ \phi : (A,d_A) \to (B,d_B), \]
see Figure 4 can be constructed as follows:

\[
\begin{array}{c}
(A,d_A) \xrightarrow{\sim} (A \boxtimes SU,d_1) \\
\downarrow j \quad \quad \downarrow \phi \\
(A \boxtimes SV,d_2) \xrightarrow{\sim} (B,d_B)
\end{array}
\]

Figure 4: Functorial factorizations

(1) The module $U$ is the free non-negatively graded $D$-module with homogeneous basis
\[ \bigcup \{ s^{-1}I_{b_n}, l_{b_n} \}, \]
where the union is over all $b_n \in B_n$ and all $n > 0$, and where $\deg(s^{-1}I_{b_n}) = n - 1$ and $\deg(l_{b_n}) = n$. In other words, the module $U$ is a direct sum of copies of the discs $D = D \cdot I_{b_n} \oplus D \cdot s^{-1}I_{b_n}$, $n > 0$. The differentials $s^{-1} : D^n \ni I_{b_n} \to s^{-1}I_{b_n} \in D^n$ induce a differential $d_U$ in $U$, which in turn implements a differential $d_S$ in $SU$. The differential $d_1$ is then given by $d_1 = d_A \otimes \text{id} + \text{id} \otimes d_S$. The trivial cofibration $i : A \to A \otimes SU$ is a minimal split RSDA defined by $i : a \mapsto a \otimes 1_\mathcal{O}$, and the fibration $p : A \otimes SU \to B$ is defined by $p = \mu_B \circ (\phi \otimes \varepsilon)$, where $\mu_B$ is the multiplication of $B$ and where $\varepsilon(I_{b_n}) = b_n$ and $\varepsilon(s^{-1}I_{b_n}) = d_B b_n$.

(2) The module $V$ is the free non-negatively graded $D$-module with homogeneous basis
\[ \bigcup \{ s^{-1}I_{b_n}, l_{b_n}, \beta_n, I_{\sigma_n}, I_{\sigma_n+1}, \ldots, I_{\sigma_n,b_n+1}, \ldots \}, \]
where the union is over all $b_n \in B_n$, $n > 0$, all $\beta_n \in \ker_n d_B$, $n \geq 0$, and all pairs $(\sigma_n, b_{n+1})$, $n \geq 0$, in $\mathcal{B}_0, \mathcal{B}_1, \ldots, \mathcal{B}_k, \ldots$, respectively. The sequence of sets
\[ \mathcal{B}_{k-1} = \{ (\sigma_n, b_{n+1}) : \sigma_n \in \ker \delta_{k-1}, b_{n+1} \in d_B^{-1}\{q_{k-1}\sigma_n\}, n \geq 0 \} \]
is defined inductively, together with an increasing sequence of differential graded $D$-algebras $(A \otimes SV_k, \delta_k)$ and a sequence of morphisms $q_k : A \otimes SV_k \to B$, by means of formulas of the type (38) - (42) (see also (32) - (36)). The degrees of the generators of $V$ are
\[ n - 1, n, n, n + 1, n + 1, \ldots, n + 1, \ldots \]
Model categorical Koszul-Tate resolution

The differential graded $\mathcal{D}$-algebra $(A \otimes SV, d_2)$ is the colimit of the preceding increasing sequence of algebras:

$$d_2|_{A \otimes SV_k} = \delta_k.$$  \hspace{1cm} (46)

The trivial fibration $q : A \otimes SV \to B$ is induced by the $q_k$-s via universality of the colimit:

$$q|_{A \otimes SV_k} = q_k.$$  \hspace{1cm} (47)

Eventually, the cofibration $j : A \to A \otimes SV$ is a minimal (non-split) RSDA, which is defined as in (1) as the canonical inclusion; the canonical inclusion $j_k : A \to A \otimes SV_k$, $k > 0$, is also a minimal (non-split) RSDA, whereas $j_0 : A \to A \otimes SV_0$ is a minimal split RSDA.

Proof. See Appendix 6.2.

Remark 1. \hspace{1cm} • If we are content with a non-functorial ‘Cof – TrivFib’ factorization, we may consider the colimit $A \otimes SV$ of the sequence $A \otimes SV_k$ that is obtained by adding only generators (see (\ref{1}))

$$I^1_{\hat{\beta}_n}, \ n \geq 0, \ \hat{\beta}_n \simeq [\beta_n] \in H_n(B),$$

and by adding only generators (see (\ref{2}) and (\ref{3}))

$$I^1_{\sigma_n}, I^2_{\sigma_n}, \ldots, \ n \geq 0, \ \sigma_n \in B_0, B_1 \setminus B_0, \ldots$$

• An explicit description of the functorial fibrant and cofibrant replacement functors, induced by the ‘TrivCof – Fib’ and ‘Cof – TrivFib’ decompositions of Theorem 5, can be found in Appendix 6.3.

5 \hfill First remarks on Koszul-Tate resolutions

In this last section, we provide first insight into Koszul-Tate resolutions. Given a polynomial partial differential equation acting on sections of a vector bundle, we obtain, via our preceding constructions, a Koszul-Tate resolution (KTR) of the corresponding algebra $R$ of on-shell functions. This resolution is a cofibrant replacement of $R$ in the appropriate undercategory of $\mathcal{D}GDA$.

In a separate paper [PP16], we give a general and precise definition of Koszul-Tate resolutions. We further show in that work that the classical Tate extension of the Koszul resolution [HT92], the KTR implemented by a compatibility complex [Ver02], as well as our just mentioned and below detailed model categorical KTR, are Koszul-Tate resolutions in the sense of this improved definition. Eventually, we investigate the relationships between these three resolutions.

Hence, the present section should be viewed as an introduction to topics on which we will elaborate in [PP16].
5.1 Undercategories of model categories

Given a category $\mathcal{C}$ and an object $C \in \mathcal{C}$, the undercategory or coslice category $C \downarrow \mathcal{C}$ is the category whose objects are the $\mathcal{C}$-morphisms $C \to D$ with source $C$, and whose morphisms between $C \to D_1$ and $C \to D_2$ are the $\mathcal{C}$-morphisms $D_1 \to D_2$ such that the triangle

$$
\begin{array}{ccc}
C & \xleftarrow{D_1} & D_2 \\
\downarrow & & \downarrow \\
D_1 & \xrightarrow{f} & D_2
\end{array}
$$

commutes. Composition and units are defined in the obvious manner.

There is a forgetful functor $\text{For} : C \downarrow \mathcal{C} \to \mathcal{C}$ that associates to each $(C \downarrow \mathcal{C})$-object its target and to each $(C \downarrow \mathcal{C})$-morphism its base $D_1 \to D_2$. It is customary to write the objects $A$ and morphisms $t$ of the undercategory simply as $\text{For}(A)$ and $\text{For}(t)$ – whenever no confusion arises (think for instance about smooth vector bundles over a fixed smooth base manifold and corresponding bundle maps). If $\mathcal{C}$ is cocomplete, the functor $\text{For}$ has a left adjoint $L_{\downarrow} : \mathcal{C} \to C \downarrow \mathcal{C}$, which takes a $\mathcal{C}$-object $D$ to the morphism $C \to C \coprod D$ and a $\mathcal{C}$-morphism $f : D_1 \to D_2$ to the commutative triangle

$$
\begin{array}{ccc}
C & \xleftarrow{\coprod D_1} & C \coprod D_2 \\
\coprod D_1 & \xrightarrow{f} & \coprod D_2
\end{array}
$$

that is induced via universality by the canonical morphisms $i_{D_2} \circ f : D_1 \to C \coprod D_2$ and $i_C : C \to C \coprod D_2$.

Note also that $\text{id} : C \to C$ is the initial object in $C \downarrow \mathcal{C}$, and that, if $\mathcal{C}$ has a terminal object $\star$, the unique morphism $C \to \star$ is the terminal object of $C \downarrow \mathcal{C}$.

The next proposition can be found in [Hir05].

**Proposition 4.** If $C$ is an object of a model category $\mathcal{C}$, the coslice category $C \downarrow \mathcal{C}$ is also a model category: a $(C \downarrow \mathcal{C})$-morphism $t$ is a cofibration, a fibration, or a weak equivalence, if $\text{For}(t)$ is a cofibration, a fibration, or a weak equivalence in $\mathcal{C}$. Moreover, if $\mathcal{C}$ is cofibrantly generated with generating cofibrations $I$ and generating trivial cofibrations $J$, the model category $C \downarrow \mathcal{C}$ is cofibrantly generated as well, with generating cofibrations $L_{\downarrow} I$ and generating trivial cofibrations $L_{\downarrow} J$.

When recalling that the coproduct in $\text{DGA}$ is the tensor product, we deduce from Theorem 3 in [BPP15a] and from Proposition 4 above that:

**Corollary 1.** For any differential graded $D$-algebra $A$, the coslice category $A \downarrow \text{DGA}$ carries a cofibrantly generated model structure given by the adjoint pair $L_{\otimes} : \text{DGA} \rightleftarrows A \downarrow \text{DGA} : \text{For}$, in the sense that its distinguished morphism classes are defined by $\text{For}$ and its generating cofibrations and generating trivial cofibrations are given by $L_{\otimes}$. 
Let us conclude by noting that for $A = \mathcal{O}$ the Quillen adjunction

$$L_\otimes : \text{DGDA} \rightleftarrows \mathcal{O} \downarrow \text{DGDA} : \text{For}$$

is obviously an isomorphism of categories.

### 5.2 Basics of jet bundle formalism

The jet bundle formalism allows for a coordinate-free approach to partial differential equations (PDE-s), i.e., to (not necessarily linear) differential operators (DO-s) acting between sections of smooth vector bundles (the confinement to vector bundles does not appear in more advanced approaches). To uncover the main ideas, we implicitly consider in this subsection trivialized line bundles $E$ over a 1-dimensional manifold $X$, i.e., we assume that $E \cong \mathbb{R} \times \mathbb{R}$.

The key-aspect of the jet bundle approach to PDE-s is the passage to purely algebraic equations. Consider the order $k$ differential equation (DE)

$$F(t, \phi(t), d_t \phi, \ldots, d^k_t \phi) = F(t, \phi, \phi', \ldots, \phi^{(k)})|_{j^k \phi} = 0,$$

where $(t, \phi, \phi', \ldots, \phi^{(k)})$ are coordinates of the $k$-th space $J^k E$ and where $j^k \phi$ is the $k$-jet of the section $\phi(t)$. Note that the algebraic equation

$$F(t, \phi, \phi', \ldots, \phi^{(k)}) = 0$$

defines a ‘surface’ $\mathcal{E}^k \subset J^k E$, and that a solution of the considered DE is nothing but a section $\phi(t)$ whose $k$-jet is located on $\mathcal{E}^k$.

A second fundamental feature is that one prefers replacing the original system of PDE-s by an enlarged system, its infinite prolongation, which also takes into account the consequences of the original one. More precisely, if $\phi(t)$ satisfies the original PDE, we have also

$$d^\ell_t(F(t, \phi(t), d_t \phi, \ldots, d^k_t \phi)) = (\partial_t + \phi' \partial_\phi + \phi'' \partial_{\phi'} + \ldots)^\ell F(t, \phi, \phi', \ldots, \phi^{(k)})|_{j^\infty \phi} =: D^\ell_t F(t, \phi, \phi', \ldots, \phi^{(k)})|_{j^\infty \phi} = 0, \quad \forall \ell \in \mathbb{N}.$$ 

Let us stress that the ‘total derivative’ $D_t$ or horizontal lift $D_t$ of $d_t$ is actually an infinite sum. The two systems of PDE-s, [48] and [50], have clearly the same solutions, so we may focus just as well on [50]. The corresponding algebraic system

$$D_t^\ell F(t, \phi, \phi', \ldots, \phi^{(k)}) = 0, \quad \forall \ell \in \mathbb{N}$$

defines a ‘surface’ $\mathcal{E}^\infty$ in the infinite jet bundle $\pi_\infty : J^\infty E \to X$. A solution of the original system [48] is now a section $\phi \in \Gamma(X, E)$ such that $(j^\infty \phi)(X) \subset \mathcal{E}^\infty$. The ‘surface’ $\mathcal{E}^\infty$ is often referred to as the ‘stationary surface’ or the ‘shell’.

The just described passage from prolonged PDE-s to prolonged algebraic equations involves the lift of differential operators $d^\ell_t$ acting on $\mathcal{O}(X) = \Gamma(X, X \times \mathbb{R})$ (resp., sending – more generally – sections $\Gamma(X, G)$ of some vector bundle to sections $\Gamma(X, K)$), to horizontal differential
operators $D_i^\ell$ acting on $\mathcal{O}(J^\infty E)$ (resp., acting from $\Gamma(J^\infty E, \pi_*^\infty G)$ to $\Gamma(J^\infty E, \pi_*^\infty K)$). As seen from Equation (50), this lift is defined by

$$(D_i^\ell F) \circ j^\infty \phi = d_i^\ell (F \circ j^\infty \phi)$$

(note that composites of the type $F \circ j^\infty \phi$, where $F$ is a section of the pullback bundle $\pi_*^\infty G$, are sections of $G$). The interesting observation is that the jet bundle formalism naturally leads to a systematic base change $X \rightarrow J^\infty E$. The remark is fundamental in the sense that both, the classical Koszul-Tate resolution (i.e., the Tate extension of the Koszul resolution of a regular surface) and Verbovetsky’s Koszul-Tate resolution (i.e., the resolution induced by the compatibility complex of the linearization of the equation), use the jet formalism to resolve on-shell functions $\mathcal{O}(E^\infty)$, and thus enclose the base change $\bullet \rightarrow X \rightarrow \bullet \rightarrow J^\infty E$. This means, dually, that we pass from $DGDA$, i.e., from the coslice category $\mathcal{O}(X) \downarrow DGDA$ to the coslice category $\mathcal{O}(J^\infty E) \downarrow DGDA$.

5.3 Revision of the classical Koszul-Tate resolution

We first recall the local construction of the Koszul resolution of the function algebra $\mathcal{O}(\Sigma)$ of a regular surface $\Sigma \subset \mathbb{R}^n$. Such a surface $\Sigma$, say of codimension $r$, can locally always be described – in appropriate coordinates – by the equations

$$\Sigma : x^a = 0, \forall a \in \{1, \ldots, r\}.$$  (52)

The Koszul resolution of $\mathcal{O}(\Sigma)$ is then the chain complex made of the free Grassmann algebra

$$K = \mathcal{O}(\mathbb{R}^n) \otimes S[\phi^{\alpha*}]$$

on $r$ odd generators $\phi^{\alpha*}$ – associated to the equations (52) – and of the Koszul differential

$$\delta_K = x^a \partial_{\phi^{\alpha*}}.$$  (53)

Of course, the claim that this complex is a resolution of $\mathcal{O}(\Sigma)$ means that the homology of $(K, \delta_K)$ is given by

$$H_0(K) = \mathcal{O}(\Sigma) \quad \text{and} \quad H_k(K) = 0, \forall k > 0.$$  (54)

The Koszul-Tate resolution of the algebra $\mathcal{O}(E^\infty)$ of on-shell functions is a generalization of the preceding Koszul resolution. In gauge field theory (our main target), $E^\infty$ is the stationary surface given by a system

$$E^\infty : D^\alpha_x F_i = 0, \forall \alpha, i$$  (55)

of prolonged algebraized (see (51)) Euler-Lagrange equations that correspond to some action functional (here $x \in \mathbb{R}^p$ and $\alpha \in \mathbb{N}^p$). However, there is a difference between the situations (52) and (55): in the latter, there exist gauge symmetries that implement Noether identities and their extensions – i.e., extensions

$$D^\beta_x G^i_{\alpha j} D^\alpha_x F_i = 0, \forall \beta, j$$  (56)
of $\mathcal{O}(J^\infty E)$-linear relations $G_{j\alpha}^i D_x^a F_i = 0$ between the equations $D_x^a F_i = 0$ of $E^\infty$, which do not have any counterpart in the former. It turns out that, to kill the homology (see (54)), we must introduce additional generators that take into account these relations. More precisely, we do not only associate degree 1 generators $\phi_i^a \star$ to the equations (55), but assign further degree 2 generators $C_j^b \star$ to the relations (56). The Koszul-Tate resolution of $\mathcal{O}(E^\infty)$ is then (under appropriate irreducibility and regularity conditions) the chain complex, whose chains are the elements of the free Grassmann algebra

$$KT = \mathcal{O}(J^\infty E) \otimes \mathcal{S}[\phi_i^a \star, C_j^b \star],$$

(57)

and whose differential is defined in analogy with (53) by

$$\delta_{KT} = D_x^a F_i \partial_{\phi_i^a \star} + D_x^b G_{j\alpha}^i D_x^a \phi_i^a \partial_{C_j^b \star},$$

(58)

where we substituted $\phi_i^a$ to $F_i$ (and where total derivatives have to be interpreted in the extended sense that puts the ‘antifields’ $\phi_i^a$ and $C_j^b$ on an equal footing with the ‘fields’ $\phi^k$ (fiber coordinates of $E$)). The homology of this Koszul-Tate chain complex is actually concentrated in degree 0, where it coincides with $\mathcal{O}(E^\infty)$ (compare with (54)).

5.4 $D$-algebraic version of the Koszul-Tate resolution

In this subsection, we briefly report on the $D$-algebraic approach to ‘Koszul-Tate’ (see [PP16] for additional details).

**Proposition 5.** The functor

$$\text{For} : \mathcal{D}A \to \mathcal{O}A$$

has a left adjoint

$$\mathcal{J}^\infty : \mathcal{O}A \to \mathcal{D}A,$$

i.e., for $B \in \mathcal{O}A$ and $A \in \mathcal{D}A$, we have

$$\text{Hom}_{\mathcal{D}A}(\mathcal{J}^\infty(B), A) \simeq \text{Hom}_{\mathcal{O}A}(B, \text{For}(A)),$$

(59)

functorially in $A, B$.

Let now $\pi : E \to X$ be a smooth map of smooth affine algebraic varieties (or a smooth vector bundle). The function algebra $B = \mathcal{O}(E)$ (in the vector bundle case, we only consider those smooth functions on $E$ that are polynomial along the fibers, i.e., $\mathcal{O}(E) := \Gamma(SE^*)$) is canonically an $\mathcal{O}$-algebra, so that the jet algebra $\mathcal{J}^\infty(\mathcal{O}(E))$ is a $D$-algebra. The latter can be thought of as the $D$-algebraic counterpart of $\mathcal{O}(J^\infty E)$. Just as we considered above a scalar PDE with unknown in $\Gamma(E)$ as a function $F \in \mathcal{O}(J^\infty E)$ (see (19)), an element $P \in \mathcal{J}^\infty(\mathcal{O}(E))$ can be viewed as a polynomial PDE acting on sections of $\pi : E \to X$. Finally, the $D$-algebraic version of on-shell functions $\mathcal{O}(E^\infty) = \mathcal{O}(J^\infty E)/(F)$ is the quotient $\mathcal{R}(E, P) := \mathcal{J}^\infty(\mathcal{O}(E))/(P)$ of the jet $D$-algebra by the $D$-ideal $(P)$. 
A first candidate for a Koszul-Tate resolution of $\mathcal{R} := \mathcal{R}(E, P) \in \mathcal{DA}$ is of course the cofibrant replacement of $\mathcal{R}$ in $\mathcal{DGDA}$ given by the functorial ‘Cof – TrivFib’ factorization of Theorem 5, when applied to the canonical $\mathcal{DGDA}$-morphism $\mathcal{O} \to \mathcal{R}$. Indeed, this decomposition implements a functorial cofibrant replacement functor $Q$ (see Theorem 6 below) with value $Q(\mathcal{R}) = SV$ described in Theorem 5

$$\mathcal{O} \to \mathcal{O} \to SV \sim \mathcal{R}.$$ 

Since $\mathcal{R}$ is concentrated in degree 0 and has 0 differential, it is clear that $H_k(SV)$ vanishes, except in degree 0 where it coincides with $\mathcal{R}$.

As already mentioned, we propose a general and precise definition of a Koszul-Tate resolution in [PP16]. Although such a definition does not seem to exist in the literature, it is commonly accepted that a Koszul-Tate resolution of the quotient of a commutative ring $k$ by an ideal $I$ is an $k$-algebra that resolves $k/I$.

The natural idea – to get a $\mathcal{J}^\infty(\mathcal{O}(E))$-algebra – is to replace $SV$ by $\mathcal{J}^\infty(\mathcal{O}(E)) \otimes SV$, and, more precisely, to consider the ‘Cof – TrivFib’ decomposition

$$\mathcal{J}^\infty(\mathcal{O}(E)) \to \mathcal{J}^\infty(\mathcal{O}(E)) \otimes SV \to \mathcal{J}^\infty(\mathcal{O}(E))/(P).$$

The $\mathcal{DGDA}$

$$\mathcal{J}^\infty(\mathcal{O}(E)) \otimes SV$$

is a $\mathcal{J}^\infty(\mathcal{O}(E))$-algebra that resolves $\mathcal{R} = \mathcal{J}^\infty(\mathcal{O}(E))/(P)$, but it is of course not a cofibrant replacement, since the left algebra is not the initial object $\mathcal{O}$ in $\mathcal{DGDA}$ (further, the considered factorization does not canonically induce a cofibrant replacement in $\mathcal{DGDA}$, since it can be shown that the morphism $\mathcal{O} \to \mathcal{J}^\infty(\mathcal{O}(E))$ is not a cofibration). However, as emphasized above, the Koszul-Tate problem requires a passage from $\mathcal{DGDA}$ to $\mathcal{J}^\infty(\mathcal{O}(E)) \downarrow \mathcal{DGDA}$. It is easily checked that, in the latter undercategory, $\mathcal{J}^\infty(\mathcal{O}(E)) \otimes SV$ is a cofibrant replacement of $\mathcal{J}^\infty(\mathcal{O}(E))/(P)$. To further illuminate the $\mathcal{D}$-algebraic approach to Koszul-Tate, let us mention why the complex (57) is of the same type as (60). Just as the variables $\phi^{(k)}$ (see (18)) are algebraizations of the derivatives $d^i_0 \phi$ of a section $\phi$ of a vector bundle $E \to X$ (fields), the generators $\phi^a_1$ and $C^a_j$ (see (55) and (56)) symbolize the total derivatives $D^a_0 \phi^i_1$ and $D^a_0 C^i_j$ of sections $\phi^a$ and $C^a_j$ of some vector bundles $\pi^a_1 F_1 \to J^\infty E$ and $\pi^a_2 F_2 \to J^\infty E$ (antifields). Hence, the $\phi^a_1$ and $C^a_j$ can be thought of as the horizontal jet bundle coordinates of $\pi^a_1 F_1$ and $\pi^a_2 F_2$. These coordinates may of course be denoted by other symbols, e.g., by $\partial^a x \cdot \phi^i_1$ and $\partial^a x \cdot C^i_j$, provided we define the $\mathcal{D}$-action as the action $D^a_0 \phi^i_1$ and $D^a_0 C^i_j$ by the corresponding horizontal lift, so that we get appropriate interpretations when the $\phi^a_1$-s and the $C^a_j$-s are the components of true sections. This convention allows to write

$$\text{KT} = J \otimes S[\partial^a_0 \cdot \phi^i_1, \partial^a_0 \cdot C^i_j] = J \otimes S \mathcal{O}(\oplus_i \mathcal{D} \cdot \phi^i_1 + \oplus_j \mathcal{D} \cdot C^i_j),$$

where $J = \mathcal{J}^\infty(\mathcal{O}(E))$, so that the space (57) is really of the type (60). Let us emphasize that (57) and (60), although of the same type, are of course not equal (for instance, the classical Koszul-Tate resolution is far from being functorial). For further details, see [PP16].
6 Appendix

6.1 Small object argument

The ‘TrivCof – Fib’ and ‘Cof – TrivFib’ factorizations of a cofibrantly generated model category can be constructed in a functorial way. The constructions use an argument that is based on the fact that the sources of the morphisms in $I$ and $J$ are small objects – the so-called small object argument (SOA), which goes back to Quillen. Although this argument is described elsewhere in the literature, we provide a compact description that allows to compare our DGDA-specific factorizations with the general SOA-factorizations.

In the following, $C$ is just a category with all small colimits, $W$ is a set of $C$-morphisms, whose sources are sequentially small, see [BPP15a, Sections 8.5 and 8.6]. Our goal is to decompose any $C$-morphism $f : A \to B$ as $A \xrightarrow{j} C \xrightarrow{q} B$, where $q \in \text{RLP}(W)$ (we will not show that this factorization leads to functorial ‘TrivCof – Fib’ and ‘Cof – TrivFib’ factorizations).

The intermediate object $C$ and the morphism $q$ will be constructed as the colimit of an $\omega$-sequence:

$$
\begin{array}{cccccccc}
A & \xrightarrow{j_0} & C_0 & \xrightarrow{j_1} & \ldots & \xrightarrow{j_n} & C_n & \xrightarrow{j_{n+1}} & C_{n+1} & \xrightarrow{j_{n+2}} & \ldots & C \\
f & \downarrow & q_0 & \downarrow & \ldots & \downarrow & q_n & \downarrow & q_{n+1} & \downarrow & \ldots & q & \downarrow \\
B = & B = & \ldots & B = & B = & \ldots & B = & \ldots & B \\
\end{array}
$$

The construction starts with the first commutative square in the preceding diagram, where $(C_0, j_0, q_0) = (A, \text{id}, f)$. Assume now that the construction is done up to the commutative square $(C_n, j_n, q_n)$ inclusively, set as usual $j_{n0} = j_n \circ \ldots \circ j_0$, and memorize that $q_n \circ j_{n0} = f$.

Before constructing the commutative square $(C_{n+1}, j_{n+1}, q_{n+1})$, recall that we wish to get $q \in \text{RLP}(W)$, i.e., that any commutative square of $C$-morphisms

$$
\begin{array}{ccc}
U & \xrightarrow{\phi} & C \\
\downarrow w & & \downarrow q \\
V & \xrightarrow{\psi} & B
\end{array}
$$

with $w \in W$ must admit a lift $\ell$. In other words, we have to build the colimit $C$ in such a way that this lift does exist. Note now that, since $U$ is sequentially small, the morphism $\phi : U \to C = \text{colim}_n C_n$ will factor through some stage of the colimit, i.e., that $\phi$ will be the composite of a morphism $\phi_n : U \to C_n$ and the transfinite composite $j_{\infty n} = \ldots \circ j_{n+2} \circ j_{n+1} : C_n \to C$:

$$
\begin{array}{cccccccc}
U & \xrightarrow{\phi_n} & C_n & \xrightarrow{j_{n+1}} & C_{n+1} & \xrightarrow{j_{n+2}} & \ldots & C \\
w & \downarrow & q_n & \downarrow & q_{n+1} & \downarrow & \ldots & q & \downarrow \\
V & \xrightarrow{\psi} & B & = & B & = & \ldots & B \\
\end{array}
$$

Therefore, we define the commutative square $(C_{n+1}, j_{n+1}, q_{n+1})$ as follows. Let $S$ be the set of all commutative squares
Model categorical Koszul-Tate resolution

\[
\begin{array}{ccc}
U & \rightarrow & C_n \\
\downarrow w & & \downarrow q_n \\
V & \rightarrow & B \\
\end{array}
\]

with \(w \in W\). Due to universality of a coproduct, we then get a commutative square

\[
\begin{array}{ccc}
\coprod_S U & \rightarrow & C_n \\
\downarrow \coprod_S w & & \downarrow q_n \\
\coprod_S V & \rightarrow & B \\
\end{array}
\]

We now define \(C_{n+1}\) to be the pushout of the upper and left arrows of the latter square, and obtain morphisms \(j_{n+1} : C_n \rightarrow C_{n+1}\) and \(\ell_{n+1} : \coprod_S V \rightarrow C_{n+1}\), and, in view of universality of a pushout, a morphism \(q_{n+1} : C_{n+1} \rightarrow B\) such that, in particular, \(q_{n+1} \circ j_{n+1} = q_n\), with the result that \(q_{n+1} \circ j_{n+1,0} = q_n \circ j_{n0} = f\).

This leads to the commutative diagram (61). We take its colimit, i.e., we set \(C = \colim_n C_n\) and get \(j_{\infty} : C_n \rightarrow C\) and \(j = j_{\infty} \circ j_{n0} : A \rightarrow C\), as well as, from the universality of a colimit, \(q : C \rightarrow B\) such that \(q \circ j_{\infty} = q_n\). Hence, the factorization

\[
f = q_n \circ j_{n0} = q \circ j_{\infty} \circ j_{n0} = q \circ j\,.
\]

To show that \(q \in \text{RLP}(W)\), consider a commutative square \(q \circ \phi = \psi \circ w\) as above. Since \(\phi = j_{\infty} \circ \phi_n\) and \(q \circ j_{\infty} = q_n\), it induces a commutative square \(q_n \circ \phi_n = \psi \circ w\) as in Figure (62), which is used to build the pushout \(C_{n+1}\). Hence, a morphism \(\ell_{n+1} : V \rightarrow C_{n+1}\) and a morphism \(\ell = j_{\infty,n+1} \circ \ell_{n+1} : V \rightarrow C\). The latter is quite easily seen to be the searched lift.

6.2 Proof of Theorem 5

The proof of functoriality of the decompositions will be given in Appendix 6.3. Thus, only Part (2) requires immediate explanations. We use again the above-introduced notation \(R_k = A \otimes SV_k\); we also set \(R = A \otimes SV\). The multiplication in \(R_k\) (resp., in \(R\)) will be denoted by \(\odot_k\) (resp., \(\odot\)).

To show that \(j\) is a minimal RSDA, we have to check that \(A\) is a differential graded \(D\)-subalgebra of \(R\), that the basis of \(V\) is indexed by a well-ordered set, that \(d_2\) is lowering, and that the minimality condition (7) is satisfied.

The main idea to keep in mind is that \(R = \bigcup_k R_k\) – so that any element of \(R\) belongs to some \(R_k\) in the increasing sequence \(R_0 \subset R_1 \subset \ldots\) – and that the DGA structure on \(R\) is defined in the standard manner. For instance, the product of \(a \otimes X, b \otimes Y \in R \cap R_k\) is defined by

\[
(a \otimes X) \odot (b \otimes Y) = (a \otimes X) \odot_k (b \otimes Y) = (-1)^{\tilde{X} \tilde{b}} (a \star b) \otimes (X \odot Y)
\]
Model categorical Koszul-Tate resolution

where ‘tilde’ (resp., *) denotes as usual the degree (resp., the multiplication in $A$). It follows that $\circ$ restricts on $A$ to $\ast$. Similarly, $d_2|_A = \delta_0|_A = d_A$, in view of (60) and (51). Finally, we see that $A$ satisfies actually the mentioned subalgebra condition.

We now order the basis of $V$. First, we well-order, for any fixed generator degree $m \in \mathbb{N}$ (see (45)), the sets

$$\{ s^{-1}\mathbb{1}_{b_{m+1}} \}, \{ \mathbb{1}_{b_m} \}, \{ \mathbb{1}_{\sigma_{m-1},b_m} \}, \{ \mathbb{1}_{\sigma_{m-2},b_m} \}, \ldots$$

of degree $m$ generators of a given type (for $m = 0$, only the sets $\{ s^{-1}\mathbb{1}_{b_1} \}$ and $\{ \mathbb{1}_{b_0} \}$ are non-empty). We totally order the set of all degree $m$ generators by totally ordering its partition (63):

$$\{ s^{-1}\mathbb{1}_{b_{m+1}} \} < \{ \mathbb{1}_{b_m} \} < \{ \mathbb{1}_{\sigma_{m-1},b_m} \} < \{ \mathbb{1}_{\sigma_{m-2},b_m} \} < \ldots$$

A total order on the set of all generators (of all degrees) is now obtained by declaring that any generator of degree $m$ is smaller than any generator of degree $m + 1$. This total order is a well-ordering, since no infinite descending sequence exists in the set of all generators. Observe that our well-order respects the degree (in the sense of (7)).

Finally, the differential $d_2$ sends the first and third types of generators (see (63)) to 0 and it maps the second type to the first. Hence, so far $d_2$ is lowering. Further, we have

$$d_2(\mathbb{1}_{\sigma_{m-1},b_m}) = \sigma_{m-1} \in (R_{k-1})_{m-1},$$

where $m - 1$ refers to the term of degree $m - 1$ in $R_{k-1}$. Since this term is generated by the generators

$$\{ s^{-1}\mathbb{1}_{b_{\ell+1}} \}, \{ \mathbb{1}_{b_{\ell}} \}, \{ \mathbb{1}_{\ell_{\sigma_{\ell-1},b_{\ell}}} \}, \ldots, \{ \mathbb{1}_{\ell_{\sigma_{\ell-1},b_{\ell}}} \},$$

where $\ell < m$, the differential $d_2$ is definitely lowering.

It remains to verify that the described construction yields a morphism $q : A \otimes SV \to B$ that is actually a trivial fibration.

Since fibrations are exactly the morphisms that are surjective in all positive degrees, and since $q|R_U = q_0|R_U = p$ is degree-wise surjective, it is clear that $q$ is a fibration. As for triviality, let $[\beta_n] \in H(B,d_B)$, $n \geq 0$. Since $\mathbb{1}_{\beta_n} \in \ker \delta_0 \subset \ker d_2$, the homology class $[\mathbb{1}_{\beta_n}] \in H(R,d_2)$ makes sense; moreover,

$$H(q)[\mathbb{1}_{\beta_n}] = [q\mathbb{1}_{\beta_n}] = [q_0\mathbb{1}_{\beta_n}] = [\beta_n],$$

so that $H(q)$ is surjective. Eventually, let $[\sigma_n] \in H(R,d_2)$ and assume that $H(q)[\sigma_n] = 0$, i.e., that $q_\sigma_n \in \text{im } d_B$. Since there is a lowest $k \in \mathbb{N}$ such that $\sigma_n \in R_k$, we have $\sigma_n \in \ker \delta_k$ and $q_k\sigma_n = dB_{n+1}$, for some $b_{n+1} \in B_{n+1}$. Hence, a pair $(\sigma_n, b_{n+1}) \in \mathcal{B}_k$ and a generator $\mathbb{1}_{\sigma_n,b_{n+1}} \in R_{k+1} \subset R$. Since

$$\sigma_n = \delta_{k+1}\mathbb{1}_{\sigma_n,b_{n+1}} = d_2\mathbb{1}_{\sigma_n,b_{n+1}},$$

we obtain that $[\sigma_n] = 0$ and that $H(q)$ is injective.
6.3 Explicit fibrant and cofibrant functorial replacement functors

(1) We proved already [BPPT1a, Theorem 4] that the factorization \((i,p) = (i(\phi), p(\phi))\) of the \(\mathbb{D} \mathbb{G} \mathbb{D} \mathbb{A}\)-morphisms \(\phi\), described in Theorem 5, is functorial, i.e., that, for any commutative \(\mathbb{D} \mathbb{G} \mathbb{D} \mathbb{A}\)-square

\[
\begin{array}{c}
\begin{array}{c}
A \\
\downarrow u
\end{array} \xrightarrow{\phi} \begin{array}{c}
B \\
\downarrow v
\end{array} \\
\begin{array}{c}
A' \\
\downarrow \phi'
\end{array}
\end{array}
\]

there is a commutative \(\mathbb{D} \mathbb{G} \mathbb{D} \mathbb{A}\)-diagram

\[
\begin{array}{c}
\begin{array}{c}
A \\
\downarrow u
\end{array} \xrightarrow{\sim} \begin{array}{c}
A \otimes \mathbb{D} \mathbb{S} \mathbb{U} \\
\downarrow p(\phi)
\end{array} \xrightarrow{i(\phi)} \begin{array}{c}
B \\
\downarrow v
\end{array} \\
\begin{array}{c}
A' \\
\downarrow \phi'
\end{array}
\end{array}
\]

(64)

The \(\mathbb{D} \mathbb{G} \mathbb{D} \mathbb{A}\)-morphism \(w\) is given by \(w = u \otimes \tilde{v}\), where \(\tilde{v}\) is the \(\mathbb{D} \mathbb{G} \mathbb{D} \mathbb{A}\)-morphism \(\tilde{v} : \mathbb{S} \mathbb{U} \to \mathbb{S} \mathbb{U}'\) defined by

\[
\tilde{v}(s^{-1}1_{b_n}) = s^{-1}1_{v(b_n)} \in \mathbb{S} \mathbb{U}' \quad \text{and} \quad \tilde{v}(1_{b_n}) = 1_{v(b_n)} \in \mathbb{S} \mathbb{U}'.
\]

**Proposition 6.** In \(\mathbb{D} \mathbb{G} \mathbb{D} \mathbb{A}\), the functorial fibrant replacement functor \(R\), which is induced by the functorial ‘\(\text{TrivCof} - \text{Fib}\)’ factorization \((i,p)\) of Theorem 5, is the identity functor: \(R = \text{id}\). In particular, all objects are fibrant.

**Proof.** When applying the decomposition \((i,p)\) to the commutative square

\[
\begin{array}{c}
\begin{array}{c}
A \\
\downarrow u
\end{array} \xrightarrow{z_A} \begin{array}{c}
\{0\} \\
\downarrow 0
\end{array} \\
\begin{array}{c}
A' \\
\downarrow z_{A'}
\end{array}
\end{array}
\]

(66)

we get

\[
\begin{array}{c}
\begin{array}{c}
A \\
\downarrow u
\end{array} \xrightarrow{\sim} \begin{array}{c}
A \otimes \mathbb{O} \\
\downarrow u \otimes \text{id}
\end{array} \xrightarrow{z_A \otimes \text{id}} \begin{array}{c}
\{0\} \\
\downarrow 0
\end{array} \\
\begin{array}{c}
A' \\
\downarrow z_{A'}
\end{array}
\end{array}
\]

(67)

It follows that the functorial fibrant replacement functor \(R\) maps \(A\) (resp., \(u\)) to \(R(A) = A \otimes \mathbb{O} \cong A\) (resp., \(R(u) = u \otimes \text{id} \cong u\)).

(2) To finish the proof of Theorem 5 we still have to show that the factorization \((j,q)\) is functorial, i.e., that for any commutative \(\mathbb{D} \mathbb{G} \mathbb{D} \mathbb{A}\)-square

\[
\begin{array}{c}
\begin{array}{c}
A \\
\downarrow u
\end{array} \xrightarrow{\phi} \begin{array}{c}
B \\
\downarrow v
\end{array} \\
\begin{array}{c}
A' \\
\downarrow \phi'
\end{array}
\end{array}
\]

(68)
there is a commutative DGDA-diagram

\[ \begin{array}{ccc}
A & \xrightarrow{j = j'(\phi)} & A \otimes SV \\
\uparrow{u} & & \uparrow{v} \\
A' & \xrightarrow{j' = j'(\phi')} & A' \otimes SV' \\
\downarrow{v} & & \downarrow{v} \\
B & & B' 
\end{array} \]  

(69)

Let us stress that the following proof fails, if we use the non-functorial factorization mentioned in Remark 2 (the critical spots are marked by \(\triangleleft\)).

Just as we constructed in Section 4, the RS\(\Delta\)A \(R = A \otimes SV\) (resp., \(R' = A' \otimes SV'\)) as the colimit of a sequence \(R_k = A \otimes SV_k\) (resp., \(R'_k = A' \otimes SV'_k\)), we will build \(\omega \in \text{DGDA}(R, R')\) as the colimit of a sequence

\[ \omega_k \in \text{DGDA}(R_k, R'_k) \].

(70)

Recall moreover that \(q\) is the colimit of a sequence \(q_k \in \text{DGDA}(R_k, B)\), and that \(j\) is nothing but \(j_k \in \text{DGDA}(A, R_k)\) viewed as valued in the supalgebra \(R\) – and similarly for \(q', q'_k, j', j'_k\). Since we look for a morphism \(\omega\) that makes the left and right squares of the diagram (69) commutative, we will construct \(\omega_k\) so that

\[ \omega_k j_k = j'_k u \quad \text{and} \quad v q_k = q'_k \omega_k. \]

(71)

Since the RS\(\Delta\)A \(A \to R_0 = A \otimes SV_0\) is split, we define

\[ \omega_0 \in \text{DGDA}(A \otimes SV_0, R'_0) \]

as

\[ \omega_0 = j'_0 u \circ_0 w_0, \]

(72)

where we denoted the multiplication in \(R'_0\) by the same symbol \(\circ_0\) as the multiplication in \(R_0\), where \(j'_0 u \in \text{DGDA}(A, R'_0)\), and where \(w_0 \in \text{DGDA}(SV_0, R'_0)\). As the differential \(\delta_{V_0}\), see Section 4 has been obtained via [BPP15a Lemma 1], the morphism \(w_0\) can be built as described in [BPP15a Lemma 2]: we set

\[ w_0(s^{-1}I_{b_n}) = s^{-1}I_{v(b_n)} \in V'_0, \quad w_0(I_{b_n}) = I_{v(b_n)} \in V'_0, \quad \text{and} \quad w_0(I_{\beta_n}) = I_{v(\beta_n)} \in V'_0, \]

(73)

and easily check that \(w_0 \delta_{V_0} = \delta_{V_0}' w_0\) on the generators. The first commutation condition (71) is obviously satisfied. As for the verification of the second condition, let \(t = a \otimes x_1 \circ \ldots \circ x_\ell \in A \otimes SV_0\) and remember (see (28)) that \(q_0 = \phi \ast q_{V_0}\) and \(q'_0 = \phi' \ast q_{V'_0}\), where we denoted again the multiplications in \(B\) and \(B'\) by the same symbol \(\ast\). Then

\[ v q_0(t) = v\phi(a) \ast v q_{V_0}(x_1) \ast \ldots \ast v q_{V_0}(x_\ell) \]

and

\[ q'_0 \omega_0(t) = q'_0 j'_0 u(a) \ast q'_0 w_0(x_1) \ast \ldots \ast q'_0 w_0(x_\ell) = \phi' u(a) \ast q'_0 w_0(x_1) \ast \ldots \ast q'_0 w_0(x_\ell). \]
It thus suffices to show that \(v q_{V_0} = q'_0 w_0\) on the generators \(s^{-1} I_{b_n}, \beta_n, I_{\beta_n}\) of \(V_0\), what follows from Equations (35) and (73) \((\alpha_1)\).

Assume now that the \(\omega_i\) have been constructed according to the requirements \((70)\) and \((71)\), for all \(\ell \in \{0, \ldots, k - 1\}\), and build their extension

\[\omega_k \in \mathcal{D} \mathcal{D} \mathcal{A}(R_k, R_k')\]

as follows. Since \(\omega_{k-1}\), viewed as valued in \(R_k\), is a morphism \(\omega_{k-1} \in \mathcal{D} \mathcal{D} \mathcal{A}(R_{k-1}, R_k')\) and since the differential \(\delta_k\) of \(R_k \simeq R_{k-1} \otimes S G_k\), where \(G_k\) is the free \(\mathcal{D}\)-module

\[G_k = \langle \beta_{\sigma_n, b_{n+1}}^k : (\sigma_n, b_{n+1}) \in \mathfrak{B}_{k-1} \rangle,\]

has been defined by means of Lemma \(1\) the morphism \(\omega_k\) is, in view of the same lemma, completely defined by degree \(n + 1\) values

\[\omega_k(I_{\sigma_n, b_{n+1}}^k) \in \delta_k^{\ell - 1}(\omega_{k-1}\delta_k(I_{\sigma_n, b_{n+1}}^k)).\]

As the last condition reads

\[\delta_k^{\ell - 1} \omega_{k-1}(\beta_{\sigma_n, b_{n+1}}^k) = \omega_{k-1}(\sigma_n),\]

it is natural to set

\[\omega_k(\beta_{\sigma_n, b_{n+1}}^k) = \beta_{\omega_{k-1}(\sigma_n), v(b_{n+1})}^k,\]

provided we have

\[(\omega_{k-1}(\sigma_n), v(b_{n+1})) \in \mathfrak{B}_{k-1}' \quad (\alpha_2) .\]

This requirement means that \(\delta_k^{\ell - 1} \omega_{k-1}(\sigma_n) = 0\) and that \(q_{k-1}' \omega_{k-1}(\sigma_n) = d_{B'} v(b_{n+1})\). To see that both conditions hold, it suffices to remember that \((\sigma_n, b_{n+1}) \in \mathfrak{B}_{k-1}\), that \(\omega_{k-1}\) commutes with the differentials, and that it satisfies the second equation \((71)\). Hence the searched morphism \(\omega_k \in \mathcal{D} \mathcal{D} \mathcal{A}(R_k, R_k')\), such that \(\omega_k|_{R_{k-1}} = \omega_{k-1}\) (where the RHS is viewed as valued in \(R_k')\). To finish the construction of \(\omega_k\), we must still verify that \(\omega_k\) complies with \((71)\). The first commutation relation is clearly satisfied. For the second, we consider

\[r_k = r_{k-1} \otimes g_1 \otimes \ldots \otimes g_\ell \in R_{k-1} \otimes S G_k\]

and proceed as above: recalling that \(\omega_k\) and \(q_k\) have been defined via Equation \((11)\) in Lemma \(1\) that \(q_k'\) and \(v\) are algebra morphisms, and that \(\omega_{k-1}\) satisfies \((71)\), we see that it suffices to check that \(q_k' \omega_k = v q_k\) on the generators \(I_{\sigma_n, b_{n+1}}^k\) – what follows immediately from the definitions \((\alpha_3)\).

Remember now that \(((R, d_2), i_r)\) is the direct limit of the direct system \(((R_k, \delta_k), i_{sr})\), i.e., that

\[
\begin{align*}
R_0 \xrightarrow{i_0} & \cdots \xrightarrow{i_{k-1}} R_k \xrightarrow{i_{k+1}} \cdots \\
& R
\end{align*}
\]

(75)
where all arrows are canonical inclusions, and that the same holds for \(((R',d'_2),i'_s)\) and \(((R'_k,d'_k),i'_s)\). Since the just defined morphisms \(\omega_k\) provide morphisms \(i'_k \omega_k \in \text{DGDA}(R_k, R')\) (such that the required commutations hold – as \(\omega_k|_{R_0} = \omega_0\)), it follows from universality that there is a unique morphism \(\omega \in \text{DGDA}(R, R')\), such that \(\omega i_k = i'_k \omega_k\), i.e., such that

\[
\omega|_{R_k} = \omega_k. \tag{76}
\]

When using the last result, one easily concludes that \(\omega j = j'u\) and \(vq = q'\omega\).

This completes the proof of Theorem 5.

**Remark 2.** The preceding proof of functoriality fails for the factorization of Remark 1. The latter adds only one new generator \(\mathbb{I}_{\beta_n}\) for each homology class \(\hat{\beta}_n \simeq [\beta_n]\), and it adds only one new generator \(\mathbb{I}^k_{\sigma_n}\) for each \(\sigma_n \in B_{k-1} \setminus B_{k-2}\), where

\[
B_r = \{\sigma_n \in \ker \delta_r : q_r \sigma_n \in \text{im} d_B, n \geq 0\}. 
\]

In \((\ast_1)\), we then get that \(v q^0 \mathbb{I}_{\hat{\beta}_n}\) and \(q^0_0 w_0 \mathbb{I}_{\hat{\beta}_n}\) are homologous, but not necessarily equal. In \((\ast_2)\), although \(\sigma_n \in B_{k-1} \setminus B_{k-2}\), its image \(\omega_{k-1}(\sigma_n) \in B'_{k-1}\) may also belong to \(B'_{k-2}\). Eventually, in \((\ast_3)\), we find that \(v q_k \mathbb{I}^k_{\sigma_n}\) and \(q'_k \omega_k \mathbb{I}^k_{\sigma_n}\) differ by a cycle, but do not necessarily coincide.

The next result describes cofibrant replacements.

**Theorem 6.** In \(\text{DGDA}\), the functorial cofibrant replacement functor \(Q\), which is induced by the functorial ‘Cof – TrivFib’ factorization \((j,q)\) described in Theorem 5, is defined on objects \(B \in \text{DGDA}\) by \(Q(B) = SV_B\), see Theorem 5 and set \(A = O\), and on morphisms \(v \in \text{DGDA}(B, B')\) by \(Q(v) = \omega\), see Equations (76), (74), and (73), and set \(\omega_0 = w_0\). Moreover, the differential graded \(\mathcal{D}\)-algebra \(SV_B\), see Proposition 1 and set \(A = O\), is a cofibrant replacement of \(B\).

**Proof.** Since the initial object in \(\text{DGDA}\) is \((O, 0)\), it suffices to apply the afore-detailed construction of the commutative diagram (69) to the commutative square

\[
\begin{array}{ccc}
O & \xrightarrow{IB} & B \\
\downarrow \text{id} & & \downarrow v \\
O & \xrightarrow{I_{B'}} & B' \\
\end{array}
\]

where \(I_B\) is defined by \(I_B(1_O) = 1_B\), and similarly for \(I_{B'}\). \(\square\)
