Controversy over large proximity induced s-wave-like pairing from a d-wave superconductor

(Dated: June 15, 2018)

We use the proximity effect to generate effective topological superconductors by placing metals with strong spin-orbit coupling in contact with a superconductor, aiming to produce Majorana zero modes useful for topologically-protected quantum computation. In recent experiments, several quintuple layers of Bi$_2$Se$_3$ were epitaxially grown on the high-$T_c$ material Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$, and conflicting experimental results were reported. We use the standard mean-field approach to study this heterostructure and find it is unlikely to have a large proximity-induced superconducting gap. Despite the seemingly correct temperature dependence, the s-wave gap claimed to be observed may not be purely superconducting in origin. Future work on the proximity-induced bulk superconducting gap and the interfacial bandstructure should shed light on this issue.

I. INTRODUCTION

The proximity effect in superconductor-metal interfaces, or the leakage of Cooper pairs from the superconductor into the metal, has been studied since its experimental discovery in 1960. The magnitude of the induced superconducting gap generally depends on the quality of the interface, external fields, and certain material-dependent properties, in particular the Fermi surfaces and energy spectra of both the superconductor and metal. The symmetry of the induced superconducting gap is typically identical to that of the superconductor unless there exists symmetry-breaking perturbations, such as the lattice-symmetry mismatch, ferromagnetism in the metal, or the presence of large spin-orbit interactions.

Recently, the application of the proximity effect to the surface states of a topological insulator (TI), with the goal to produce the topological superconductivity, has stimulated intense theoretical and experimental effort. In addition to s-wave superconductors, d-wave superconductors also show interesting pairing effect on the surface states of a TI. Wang et al. observe a surprisingly large s-wave-like pairing gap on the top surface of a seven-quintuple-layer-thick Bi$_2$Se$_3$ film on Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ (BSCCO) by using angle-resolved photoemission spectroscopy (ARPES). By applying a suitable incident photon energy (approximately 50 eV), at which the contribution from the surface states dominates that from the bulk states, a gap of up to 15 meV on the outermost surface states of the Bi$_2$Se$_3$/BSCCO system is detected. The change of the pairing symmetry from d-wave in BSCCO to s-wave-like on the surface states from the proximity effect is claimed to reflect a nontrivial coupling in this system. However, two separate experimental groups with similar setups do not reproduce the proximity-induced pairing gap on the Bi$_2$Se$_3$/BSCCO. Earlier tunneling measurements suggest the proximity induced gap at the interface is d-wave. These conflicting observations prompt us to address the issue theoretically and ask whether such a large proximity-induced s-wave gap is possible.

In this paper, we use the tunneling model pioneered by McMillan to study the superconducting proximity effect between Bi$_2$Se$_3$ and BSCCO. We assume the interface between the superconductor and the metal is clean or with only weak random impurities, and the superconducting gap in BSCCO is identical for all coupling strengths between BSCCO and Bi$_2$Se$_3$. We model the superconductivity within BSCCO via mean-field, and evaluate within Bi$_2$Se$_3$ the induced pairing amplitude, defined as the sum of the expectation value of Cooper pairs in momentum space, for a range of symmetries. Our results show that the proximity-induced superconducting gap is small and mainly d-wave, and the unambiguous way to find the condensates is through the evaluation of pairing amplitudes. The smallness of s-wave and $p \pm ip$ pairing amplitudes supports the absence of a large induced s-wave-like superconducting gap.

Based on our results, we suggest the discrepancies between the experimental are due to different interface coupling strengths between Bi$_2$Se$_3$ and BSCCO across the various samples. The observed gap in Ref. may not purely be due to superconductivity, but also to a mass gap generated by bands crossings caused by large interfacial tunnelings compared with the samples used in Ref. and Ref. The growth temperature in Ref. is certainly much higher than that in Ref. suggesting the interface tunneling strength is larger in sample of Ref. Further analysis on the symmetry of the bulk superconducting gap of Bi$_2$Se$_3$ in the samples of Ref. should reveal its d-wave nature, as the bands overlap between the bulk bands of Bi$_2$Se$_3$ and BSCCO should be smaller than the overlap between the surface states. Another way to verify our claim is to measure the band structure of Bi$_2$Se$_3$ at the interface, which should show a d-wave single particle gap structure with lobes pointing in the nodal direction when the system temperature is higher than $T_c$, the superconducting transition temperature of BSCCO.
We note that earlier work by Z. X. Li et. al. has also addressed the same issue with a two-bands model of the Bi$_2$Se$_3$. In their work there are two quantum well states other than the surface state present at the Fermi surface for the 7QL-thick Bi$_2$Se$_3$. They also introduce small (around 100 meV) repulsive and attractive interactions within the Bi$_2$Se$_3$. At the top layer (away from the interface with BSCCO) they find $s$-wave dominant pairing due to the suppression of $d$-wave pairing near the $\Gamma$ point and claim that disorder could further enhance $s$-wave pairing. The proximity induced superconducting gap magnitude in their paper is also around 1 meV with similar tunneling strength. Their results support the reports in Refs. 14 and 15 of the absence of a superconducting gap despite its $s$-wave gap structure. Furthermore, the dominant $s$-wave pairing gap in Ref. 13 is the result of multilayer structure of Bi$_2$Se$_3$ (through enforcing $s$-wave interactions in Bi$_2$Se$_3$ and disorder, which prefer $s$-wave) and choice of Fermi surface around $\Gamma$ point. This mechanism is different from our work where the formation of $s$-wave-like gap is the combined effects of superconducting proximity effect and hybridization of bands between Bi$_2$Se$_3$ and BSCCO.

We introduce our model Hamiltonians for the BSCCO/Bi$_2$Se$_3$ system. Assuming good contact surface between the two, we compute various pairing amplitudes and proximity-induced tunneling gaps in the surface state of Bi$_2$Se$_3$ at different tunneling strengths. In Section III we discuss other possible factors which could enhance the proximity induced superconductivity. In Section IV we find the combined effect of strong hybridization of bands and superconducting proximity effect gives rise to $s$-wave-like gap structure. In Section V we summarize our results and suggest possible experimental approaches to verify our claim.

II. PROXIMITY EFFECT: BSCCO AND Bi$_2$Se$_3$

We start with the model Hamiltonian describing the Bi$_2$Se$_3$, a type of three dimensional topological insulator (TI), grown on top of the BSCCO. We assume only single metallic layer in the Bi$_2$Se$_3$ in our computation, which can be viewed as one of the two dimensional surfaces of the three dimensional topological insulator Bi$_2$Se$_3$ in contact with BSCCO if the bulk band were insulating. The motivations for forming this heterostructure is to produce effective $p \pm ip$ superconductivity, a form of topological superconductivity, on its interface. The edge modes or vertex states of the topological superconductor host the Majorana modes, the simplest anyon which could be useful for quantum computations.

To describe the superconducting proximity effect between surfaces of BSCCO and Bi$_2$Se$_3$, we use the following single band bilayer model Hamiltonian:

\[
H = H_{\text{BSCCO}} + H_{\text{Bi}_2\text{Se}_3} + H_t
\]

\[
H_{\text{BSCCO}} = \sum_{\vec{k},\sigma} d_{\vec{k},\sigma}^\dagger (E_d(\vec{k}) - \mu_d) d_{\vec{k},\sigma} + \sum_{\vec{k},\vec{k}' \neq \vec{k}} V(\vec{k},\vec{k}') d_{\vec{k} \downarrow} d_{-\vec{k},\downarrow}^\dagger d_{-\vec{k} \uparrow}^\dagger d_{\vec{k},\uparrow}^\dagger
\]

\[
H_{\text{Bi}_2\text{Se}_3} = \sum_{\vec{k},\alpha,\beta} c_{\vec{k},\alpha}^\dagger (E_c(\vec{k})_{\alpha\beta} - \mu_c) c_{\vec{k},\beta}
\]

\[
H_t = \sum_{\vec{k},\sigma} (t_k c_{\vec{k},\sigma}^\dagger d_{\vec{k},\sigma}^\dagger + t_k^* c_{\vec{k},\sigma}^\dagger c_{\vec{k},\sigma}^\dagger c_{\vec{k},\sigma}).
\]

Here $H_{\text{BSCCO}}$, $H_{\text{Bi}_2\text{Se}_3}$, and $H_t$ describe the Hamiltonian for two dimensional surface of BSCCO, surface state of Bi$_2$Se$_3$, and the single particle tunneling terms between the two surfaces. $H$, $\alpha$, $\beta$ denote spin indices, $d_{\vec{k},\sigma}$, and $c_{\vec{k},\sigma}$ the electron annihilation operators of BSCCO and Bi$_2$Se$_3$ in momentum space representation, and $\vec{k} = (k_x, k_y)$ is the linear momentum of the two dimensional surface. $I_{\alpha\beta}$ is the identity matrix, and $E_c(\vec{k})_{\alpha\beta}$ is a $2 \times 2$ matrix characterizing the spin orbit interaction of surface state of TI. Attractive $V(\vec{k},\vec{k}')$ with $d$ wave symmetry is assumed to give $d$-wave superconductivity of BSCCO under the BCS mean field approximation. The tunneling amplitude $t_k$ is proportional to the wavefunctions overlap between that of BSCCO and Bi$_2$Se$_3$. We have assumed few or weak random nonmagnetic impurities such that spin and momentum are conserved in the tunneling term, and constant tunneling amplitude nearby the relevant Fermi level ($t_k = t$).

![Figure 1](https://example.com/figure1.png)

**FIG. 1.** (a) Energy dispersion of surface state of Bi$_2$Se$_3$ described in Eq. 1. The relevant energy scale in the main text is colored in shaded blue region. (b) We plot the Fermi surfaces of Bi$_2$Se$_3$ including the warping cubic terms at $\mu_2/h \approx 1.3$ (red thin line) and $\mu_2/h \approx 2.6$ (blue thick dashed line), and BSCCO (green thick line). The $\mu_2/h \approx 2.6$ is just for illustrating the hexagonal symmetry of the Fermi surface which is difficult to see with the Fermi level ($\mu_2/h \approx 1.3$) set by the experiments.

The explicit form of $E_d(\vec{k})$ and $E_c(\vec{k})_{\alpha\beta}$ are obtained from the tight binding models, with parameters specified from first principle studies for Bi$_2$Se$_3$ and BSCCO.
The single band dispersion for BSCCO is:

\[
\bar{E}_d(\vec{k}) = E_d(\vec{k}) - \mu_d = -h(\cos(k_xa_1) + \cos(k_ya_1)) \\
+ h' \cos(k_xa_1) \cos(k_ya_1) - h''(\cos(2k_xa_1) + \cos(2k_ya_1)) \\
- h'''(\cos(2k_xa_1) \cos(k_ya_1) + \cos(k_xa_1) \cos(2k_ya_1)) \\
+ h''''(2\cos(2k_xa_1) \cos(2k_ya_1)) - \mu_d
\]  

(2)

Here \( h = 0.2975 \text{eV}, \ h' = 0.1636 \text{eV}, \ h'' = 0.0259 \text{eV}, \ h''' = 0.0558 \text{eV}, \ h'''' = 0.0510 \text{eV}, \ \mu_d = -0.1305 \text{eV}, \ a_1 \approx 3.82 \text{Å.} \) For the Bi$_2$Se$_3$ crystal, to account for the C$_6$ crystal symmetry and different orientations on the proximity effect seen in the experiments, we include the warping terms\(^2\) in our model Hamiltonian. From Ref.\(^2\) the low energy dispersion of Bi$_2$Se$_3$ close to the Brillouin zone center is given by

\[
\bar{E}_c(\vec{k}) = E_c(\vec{k}) - \mu_c \\
= p_0 + p_1(k_x^2 + k_y^2) + p_2(\sigma_xk_y - \sigma_yk_x) \\
+ p_3(k_x^3 + k_y^3)\sigma_z - \mu_c
\]  

(3)

where \( p_0 = 0.035 \text{ eV}, \ p_1 = 1.38556 \text{ eV Å}^2, \ p_2 = 0.795 \text{ eVÅ}, \ p_3 = 0.3535 \text{ eV Å}^3, \ k_x = k_x \pm ik_y, \) and \( \sigma_x, \ \sigma_y, \) and \( \sigma_z \) are the \( 2 \times 2 \) Pauli spin matrices. The \( p_2 \) term is the Rashba spin orbit term. For our calculations, we need to extend this low energy Hamiltonian to the whole Brillouin zone in momentum space and keep the single Dirac-cone-like structure. The quadratic \( k \) terms have undesired behavior in the large-\( k \) region and does not provide the consistent band structures compared with experiments at large momenta. To include the warping terms and avoid the issues of inconsistency at large \( k \), we keep the linear term unchanged, remove the quadratic terms, and replace \( k_xa_2 \) with \( \sin(k_xa_2) \) and \( k_ya_2 \) with \( \sin(k_ya_2) \) for the third order warping terms. Here \( a_2 = 4.138 \text{Å} \) is the lattice constant of Bi$_2$Se$_3$. The low energy dispersion in Eq.\(^2\) is then modified as:

\[
\bar{E}_c(\vec{k}) = p_0 + p_2(\sigma_xk_y - \sigma_yk_x) \\
+ \frac{p_3}{a_2^2}(2\sin^2(k_xa_2) - 6\sin(k_xa_2)\sin^2(k_ya_2)) \sigma_z - \mu_c
\]  

(4)

The chemical potential \( \mu_c \) exhibiting surface states of Bi$_2$Se$_3$ is estimated to be around 0.4 eV for the relevant experiment\(^5\). Noting that Eq.\(^1\) is not of tight binding form but from an effective low energy Hamiltonian of surface state of Bi$_2$Se$_3$ with parameters fixed by first principle studies\(^2,\)\(^6\). The first order derivative of \( \bar{E}_c(\vec{k}) \) is discontinuous at zone boundary \( (k_xa_2, k_ya_2 \text{ being } \pm \pi) \) after imposing periodic boundary condition. For the low energy limit (energy scale less than \( p_2a_2 \sim 3.2 \text{ eV} \)) discussed in this paper this artifact does not enter into our equations or modify our results. The region of relevant energy scale in our discussion here is plotted in Fig.\(^1\)(a).

For the numerical computations shown below we take nearest neighbor hopping \( h \) of BSCCO in Eq.\(^2\) as the energy unit. We use \( k_xa_1 \equiv \tilde{k}_x \) and \( k_ya_1 \equiv \tilde{k}_y \) as dimensionless momentum space parameters although there is a minor difference in their lattice size \( (a_2/a_1 \approx 1.08) \). In this unit the \( d \)-wave superconducting gap is defined as

\[
\Delta(\vec{k}) = \sum_{\vec{k}'} V(\vec{k} - \vec{k}')\langle d_{\vec{k},\uparrow}^\dagger d_{\vec{k}',\downarrow}^\dagger \rangle \\
= \Delta^*(\cos(k_x) - \cos(k_y))
\]  

(5)

Here the gap magnitude \( |\Delta| \approx 40 \text{ meV} \) (or \( |\Delta|/h \approx 0.13 \)) is assumed to be fixed (termed the "bulk limit" below) by viewing the superconductivity of BSCCO not influenced by the contact of Bi$_2$Se$_3$. The expectation value is taken with the ground state of the whole mean field Hamiltonian. In principle we may also compute this gap magnitude self consistently, as shown for the model calculations in Appendices\(^\text{A,C} \) by fixing the interaction strength \( V(\vec{k},\vec{k}') \). The obtained proximity induced superconducting gaps or pairing amplitudes are smaller compared with those obtained with the bulk limit. To obtain an upper bound on the proximity induced gap on Bi$_2$Se$_3$ we stick with this bulk limit in the main text of the paper.

We identify the proximity induced superconductivity in Bi$_2$Se$_3$ by computing two quantities: the pairing amplitude and the quasiparticle energy gap. The pairing amplitude \( A_i \) is defined as:

\[
A_i = -\sum_{\vec{k}} f_\beta f_\beta' \langle c_{\vec{k},\alpha}^\dagger c_{-\vec{k}',\beta} \rangle = \tilde{A}_i f_i
\]  

(6)

with \( f_i \) being the symmetry factor and \( i \) denoting \( s, p, p \pm ip, \) or \( d \) wave symmetry \( (a \) and \( b \) are spin indices, \( f_x = 1, \ f_p = \sin(k_x), \ f_p \pm ip = \sin(k_x) \pm i \sin(k_y), \) and \( f_d = \cos(k_x) - \cos(k_y). \) \( f'_i \) has similar definition as \( f_i \) with \( \tilde{k} \) replaced by \( \vec{k}' \). This \( f_i f'_i \) geometric factor comes from the angular expansions of \( V(\vec{k} - \vec{k}') \) and \( A_i \) is the corresponding magnitude. Even (spatial) wave symmetry has odd spin angular momentum and vice versa, as required by the Pauli exclusion principle. This dimensionless pairing amplitude directly reflects the amount of Cooper pairs formed at Bi$_2$Se$_3$, but it is not directly probed by tunneling measurement\(^1\) nor spectroscopy like ARPES\(^14-16 \). The physical quantity probed in these experiments is the quasiparticle energy gap. We identify the energy gap due to proximity effect in two approaches: One is from the density of state (DOS) of Bi$_2$Se$_3$, and another is obtained from the numerical results of energy bands difference in the diagonalized bases of total Hamiltonian \( H \). The DOS calculation is done with Hartree approximation (ignoring the exchange term), as shown in Appendix\(^\text{A}\) and perform the momentum integral on the imaginary part of electron Green’s function of Bi$_2$Se$_3$. From the shape of the DOS we may identify the gap symmetry and magnitude, but will not have momentum space resolution. The numerically obtained energy bands difference with momentum dependence complements this.

From Eq.\(^1\) we find the desired surface state band structure of Bi$_2$Se$_3$, showing clear hexagonal Fermi surface at larger chemical potential as shown in Fig.\(^1\)(b).
This hexagonal structure is not apparent at the experimental relevant Fermi level. However, with the breaking of circular symmetry, the presence of Zeeman like $\sigma_z$ term, and the crystal orientation of $\text{Bi}_2\text{Se}_3$ which is $45^\circ$ or $15^\circ$ different from that of BSCCO, we have generated s-wave, p-wave, and $p \pm ip$-wave pairing in additional to $d$-wave pairing on the $\text{Bi}_2\text{Se}_3$ surface. The crystal orientation difference, as demonstrated in Fig.1(b), is important for the existence of s-wave pairing. There would be no s-wave pairing if rotated by $15^\circ$ (or equivalent $45^\circ$ with $C_6$ symmetry in warping corrected $\text{Bi}_2\text{Se}_3$ surface state) due to the $d$-wave pairing from the BSCCO and the alignment of symmetry axes of $\text{Bi}_2\text{Se}_3$ in nodal directions. Same argument also applies to the lacking of s-wave pairing without the inclusion of warping terms. Aforementioned pairing amplitudes are denoted by $A_s$, $A_p$, $A_{p \pm ip}$, and $A_d$ and their values with different tunneling strengths $t$ are listed in Table I.

Table I. Various possible pairing amplitudes at different tunneling strengths $t$. Gap magnitude of BSCCO is fixed at $\Delta/h \approx 0.13$ with pairing amplitudes evaluated with $160 \times 160$ k-points. $\tilde{A}_i$ is defined as $\tilde{A}_i = A_i \times 10^{-5}$.

| $t$  | $\tilde{A}_s$ | $\tilde{A}_p$ | $\tilde{A}_d$ | $\tilde{A}_{p \pm ip}$ |
|------|---------------|---------------|--------------|-------------------------|
| 0.01 | -7.1968       | -2.9080       | 2.7588       | -2.0932                 |
| 0.1  | -8.7976       | -4.9422       | 209.67       | -47.220h                |

| 2.0  | 1475.2        | 2659.3        | 41063        | 6947.7                  |

III. OTHER RELEVANT FACTORS

We have assumed smooth interface and computed only the proximity induced gap at the surface of $\text{Bi}_2\text{Se}_3$ in direct contact with BSCCO. In the actual experiments, the ARPES were done on the opposite surface of a few quintuple layers thick $\text{Bi}_2\text{Se}_3$. From the ARPES data the Fermi level of a few QL thick $\text{Bi}_2\text{Se}_3$ actually crosses the bulk band and the bulk is not insulating. Furthermore, in the growth process, there are always some impurities generated at the bulk or surface of $\text{Bi}_2\text{Se}_3$. Last but not least, the lattice size of BSCCO is $3.8\text{\AA}$ and that of $\text{Bi}_2\text{Se}_3$ is $4.138\text{\AA}$. The latter is taken to be the same as that of BSCCO in our mean field calculations. We discuss how these factors influence our results below.

The simplest way to consider the proximity effect on the other surface of $\text{Bi}_2\text{Se}_3$ is to assume the two surfaces are tunnel-coupled. In this case the model becomes trilayer rather than bilayer one. For moderate tunneling strength the multilayer structure always has smaller pairing amplitude compared with bilayer system (as shown in the generic model discussion in Appendix B). Thus the simplest way to include this finite thickness effect of $\text{Bi}_2\text{Se}_3$ will not be able to account for the $15 \text{meV}$ measured in Ref.16.

We may include the bulk band by treating it as a two bands metal on the metallic surface in contact with the BSCCO. This is because the Fermi surface of the $\text{Bi}_2\text{Se}_3$ also cut through the bulk band, and in some literature it is called a topological metal. In principle the bulk bands
share the tunneled Cooper pairs from the superconductor with the surface band, therefore at the same tunneling strength the pairing gap at the surface decreases compared with that without the inclusion of bulk band in a self consistent calculation. If the two bands are coupled via repulsive interactions, the pairing gaps at different bands could be different as suggested to be measured experimentally in Ref.16, where different frequencies are used to distinguish the measurement of bulk from that of surface. As both bands share the superconducting gap from BSCCO, the inclusion of bulk gap tends to lower the proximity induced gap of the surface band, rendering it even smaller than 0.6 meV at $t/h = 0.67$.

The impurities in the bulk and surfaces of Bi$_2$Se$_3$ could in general suppress the nodal pairings, and make s-wave pairing dominant for sufficient thick samples. The drawback is the scattering from the impurities also tend to diminish the pairing gap, making it unlikely to achieve the large ($\geq 10$ meV) proximity induced s-wave-like gap. Another way to enhance this s-wave component is to introduce an isotropic, attractive interaction as in Ref.19. However, in our zero temperature calculations, including this attractive interaction will make the Bi$_2$Se$_3$ superconducting without coupling to BSCCO. The undoped Bi$_2$Se$_3$ has not been seen to be superconducting in the experiment, and therefore we do not include this factor in our discussion. It is possible that interfacial s-wave superconductivity could be formed at the interface of BSCCO and Bi$_2$Se$_3$, and we verify this interfacial attractive interaction does enhance the s-wave pairing amplitude in Bi$_2$Se$_3$ layer but the enhancement is small (around 25%) with moderate interaction strength (twice the attractive interaction strength of BSCCO at $t/h = 1.3$).

There are two other factors which could possibly enhance the pairing amplitudes in this system. One is the lattice mismatch issue, and the other is the possibility of forming enlarged Fermi surface in Bi$_2$Se$_3$ due to its growth on BSCCO (the gating issue). For different Fermi surface structure the lattice mismatch could usually lead to more overlaps in bands when taking the lattice mismatch into considerations (see the generic model discussion in Appendix C). However, given the small lattice mismatch (lattice size ratio $a_2/a_1 \approx 4.1/3.8 \approx 1.08$) the major enhancement of proximity induced gap should come from the enlargement of Fermi surface on the Bi$_2$Se$_3$ surface. Based on our calculations, even raising to twice of the original chemical potential of Bi$_2$Se$_3$ does not significantly enhance the proximity induced gap magnitude (around twice and also mainly $d$-wave-like). Judging from the discrepancy of shape and gap magnitude with ARPES data shown in Ref.16, and the fact that the estimates we have here should be the theoretical upper bound for a clean interface, we tend to support the experimental results in Refs.14 and 15.

![DOS](image)

**FIG. 3.** (a) The DOS of Bi$_2$Se$_3$ at $t/h = 2$ with superconducting gap in BSCCO $\Delta/h \approx 0.13$. All other parameters are the same as those in the main text. Frequency in unit of meV. (b) Gap structure (red dots) at $t/h = 2$ compared with the experimental data (black square) shown in Ref.16.

### IV. POSSIBLE S-WAVE GAP

How do we explain the experimental findings in Ref.16? It is suggested that the grounding issues could lead to incorrect readings of superconducting gaps, but this factor might not reflect the temperature dependence of the gap in a way correlated with the BSCCO observed in Ref.16. We suspect the observed s-wave-like gap is the result of strong hybridizations between the bands of Bi$_2$Se$_3$ and BSCCO due to the large tunneling amplitude. In this case the observed gap is not purely due to proximity induced superconductivity, but also the mass gap generated by single particle tunneling.

We find for $t/h > 2$ the single particle mass gap for all directions (both nodal and antinodal ones) is generated even if we turned off the superconductivity in BSCCO, and we use this as the upper bound of tunneling amplitude as no gap opening along antinodal lines is found at $T > T_c$ in Ref.16. From Table I we find at $t/h = 2$ the proximity induced pairing amplitudes are still dominated by $d$-wave pairing, but the shape of the gap as shown in Fig.3(b) is similar to s-wave. The gap magnitude read out from the DOS of Bi$_2$Se$_3$ in Fig.3(a) is around 13.4 meV at $t/h = 2$, and no gap along the antinodal direction of BSCCO is seen when the superconductivity is turned off. The lobes of this mass gap is pointing along the nodal directions of BSCCO, making it look like s-wave gap structure, as shown in Fig.3(b) when the superconductivity is turned on.

The aforementioned s-wave-like gap opening is consistent with the temperature dependence observed in Ref.16, i.e. no gap at $T > T_c$ and s-wave-like gap at $T < T_c$. At $t/h = 2$ the onset of proximity induced superconductivity is estimated, from the change of DOS, to be around 60K which is roughly consistent with the data. Factoring in the aforementioned lattice mismatch, enlarged Fermi surfaces, possible s-wave pairing interaction at the interface, could possibly give rise to the scale and features similar to the experimental results in Ref.16. We emphasize that the s-wave-like structure shown in Fig.4 is the combined results of bands hybridization between Bi$_2$Se$_3$ and BSCCO and the $d$-wave superconductivity from BSCCO. The proximity induced pairing amplitude...
in Bi$_2$Se$_3$ is still dominated by $d$-wave. This scenario is different from the dominant $s$-wave pairing discussed in Ref.19, in which the $s$-wave pairing amplitude is mainly from the proximity induced superconductivity.

V. CONCLUSION

In this paper, we use the mean-field approach to compute the superconducting pairing amplitudes and gap magnitude in a superconducting-metal interface. We find the pairing amplitude is mainly $d$-wave except at small $t$ ($t/h \leq 0.01$ with $h$ the nearest neighbor hopping amplitude in BSCCO). With reasonably large $t$ ($2 > t/h \geq 0.1$), the gap structure, obtained from our DOS and band calculations, is mainly $d$-wave with gap magnitude less than 1 meV.

We suggest one possible reason why the large $s$ wave like gap ($\sim 15$ meV) is observed in Ref.16 while the other two similar setups$^{14,15}$ show no significant ($> 5$ meV) proximity induced gap. We argue the gap in Ref.16 is not purely due to superconductivity, but rather contains a large component due to a large tunneling amplitude ($t/h \geq 2$). The pairing amplitude evaluated at large $t$ are still dominated by the $d$-wave channel, and its mixing with the single-particle gap makes it more $s$-wave-like, as shown in Fig.3(b). Thus, we propose that sample-to-sample variations in interfacial coupling between Bi$_2$Se$_3$ and BSCCO explain the discrepancy between the observed gaps, and also that the induced superconductivity is much smaller than would be naively concluded from the observations of Ref.16.

A piece of supporting evidence for this claim, as also pointed out in Ref.14 and 15, is the lack of superconducting coherence peak in the observed ARPES spectrum in Ref.16. Furthermore, it is claimed$^{16}$ that the bulk conducting bands of Bi$_2$Se$_3$ are also superconducting, but with a much smaller gap. As the bulk bands are further away from the quasiparticle bands in BSCCO and their effective tunneling amplitudes are smaller due to smaller wave function overlaps, it is possible that the gap induced in the bulk bands is dominated by the $d$-wave superconducting gap and the measured gap might be mainly from proximity induced superconductivity. More detailed measurements of the bulk spectrum should shed light on this issue. This case also serves as a cautionary example: measuring the temperature dependence of a gap at an interface is not sufficient to show that the gap is superconducting in origin.

Appendix A: Perturbative results for proximity induced pairing amplitude

We derive the analytical, perturbative results of superconducting proximity effect for some generic bilayer and trilayer systems using Green’s functions formalism. The perturbative term is the attractive interaction in the superconducting layer, and we further assume the tunneling amplitude is small to simplify our results. The form of self energy in the Green’s function is assumed to take the Hartree form (neglecting exchange interactions) with mean field approximations. The real part of self energy just shifts or renormalizes the chemical potential. Under these approximations the self consistent equation of the superconducting layer is the same as the uncoupled one, and the leading term of pairing amplitude in the first metallic layer is proportional to $t^2$. The generic model Hamiltonian we considered in the Appendix is:

$$H = \sum_{\vec{k},l,\sigma,\sigma',\tau} (\epsilon_{l}(\vec{k}) - \mu_{l})c_{\vec{k}l\sigma}^{\dagger}c_{\vec{k}l\sigma'} + \sum_{\vec{k},i<j,\sigma} t_{ij} (c_{\vec{k}i\sigma}^{\dagger}c_{\vec{k}\sigma}c_{\vec{k}j\sigma}^{\dagger}c_{\vec{k}\sigma}) + \sum_{\vec{k},\vec{q},l,l',\sigma,\sigma'} V_{ll'}(\vec{q})c_{\vec{k}l\sigma}^{\dagger}c_{\vec{q}l'\sigma}c_{\vec{k}-\vec{q}l'\sigma}c_{\vec{k}l\sigma}$$

Here $l, i, j$ range from 1, 2, 3, ..., $N$ with 1 denote electron/hole operators on the superconducting layer and 2, 3 (say $N = 3$) denote two bands in one metallic layer or two metallic layers. In this model Hamiltonian we consider the usual form of density density interactions. Below we show explicitly the calculations for three cases: Bilayer, trilayer, and metallic layer with spin orbit interactions.

1. Two layers with single band

Here we perform perturbative calculations via the Green’s function formalism. Using the four component Nambu spinor bases $\Psi_{\vec{k}} = \begin{pmatrix} c_{\vec{k}1\uparrow}^{\dagger} & c_{\vec{k}1\downarrow} & c_{\vec{k}2\uparrow}^{\dagger} & c_{\vec{k}2\downarrow} \end{pmatrix}^T$, the Green’s function is given by

$$G(\vec{k}, \tau) = -\langle T_{\tau} \Psi(\vec{k}, \tau) \Psi^\dagger(\vec{k}, 0) \rangle$$

For $V_{ll'}(\vec{q}) = 0$ the retarded Green’s function $G_0(\vec{k}, \omega)$ takes the form:
with $\tilde{c}_i(\tilde{k}) = \epsilon_i(\tilde{k}) - \mu_i$. Turning on $V_1(q) \neq 0$ gives self energy correction on the bare Green’s function $G_0(\tilde{k}, \omega)$ from perturbations in $V_1(q)$. We take $q = \tilde{k} + \tilde{k}'$ as in the BCS theory and denote $V_1(q) = V_1(\tilde{k}, \tilde{k}') = V_1$ in the following. The perturbation in $V_1$ gives:

$$G(\tilde{k}, \omega)^{-1} = G_0(\tilde{k}, \omega)^{-1} - \Sigma(\tilde{k}, \omega).$$

(A4)

Based on first order perturbation in $V_1(q)$, the Hartree corrected $\Sigma(\tilde{k}, \omega)$ takes the following form

$$\Sigma_H = \begin{pmatrix}
\Sigma_1(\tilde{k}, \omega) & S_1(\tilde{k}, \omega) & 0 & 0 \\
S_1(\tilde{k}, \omega) & -\Sigma_1(-\tilde{k}, -\omega) & 0 & 0 \\
0 & 0 & \Sigma_2(\tilde{k}, \omega) & S_2(\tilde{k}, \omega) \\
0 & 0 & S_2(\tilde{k}, \omega) & -\Sigma_2(-\tilde{k}, -\omega)
\end{pmatrix}$$

with $\rho(\tilde{k}, \omega) \equiv -\frac{1}{\pi} \Im(G(\tilde{k}, \omega))$, $f_i(\omega) = \theta(\mu_i - \omega)$ the Fermi-Dirac distribution at zero temperature, and

$$\begin{align*}
\Sigma_1(\tilde{k}, \omega) &\simeq \sum_{\tilde{k}'} \frac{V_1}{2} \int_{-\infty}^{\infty} d\omega \rho_{11}(\tilde{k}', \omega) f_1(\omega) \quad \text{(A5)} \\
\Sigma_2(\tilde{k}, \omega) &\simeq \sum_{\tilde{k}'} \frac{V_2}{2} \int_{-\infty}^{\infty} d\omega \rho_{33}(\tilde{k}', \omega) f_2(\omega) \quad \text{(A6)} \\
S_1(\tilde{k}, \omega) &\simeq \sum_{\tilde{k}'} V_1 \int_{-\infty}^{\infty} d\omega \rho_{12}(\tilde{k}', \omega) f_1(\omega) \quad \text{(A7)} \\
S_2(\tilde{k}, \omega) &\simeq \sum_{\tilde{k}'} V_2 \int_{-\infty}^{\infty} d\omega \rho_{34}(\tilde{k}', \omega) f_2(\omega), \quad \text{(A8)}
\end{align*}$$

with $\tilde{\omega} = \omega + i\eta$ for retarded Green’s function. For $t = 0$ we have $\langle c^\dagger_{k1} c^\dagger_{-k1} \rangle = 0$ and

$$\langle c^\dagger_{k2} c^\dagger_{-k2} \rangle = \frac{-S_1(\tilde{k}, \omega)}{2\sqrt{(\tilde{\epsilon}_1(\tilde{k}) + \Sigma_1(\tilde{k}, \omega))^2 + S_1(\tilde{k}, \omega)^2}} \quad \text{(A14)}$$

The single particle self energy correction terms $\Sigma_i$ can be absorbed into the renormalized chemical potential $\mu_i$, and we remove this term in the following expressions for simplicity.

By combining Eq. (A12) with Eq. (A13), we get the self consistent gap equation in the BCS theory by identifying superconducting gap $\Delta_1(\tilde{k}) = S_1(\tilde{k}, \omega)$. For small but finite $t$ we take the leading $t^2$ correction in the evaluation of frequency integral for $G(\tilde{k}, \omega)_{34}$. Under this small $t$ approximation the pole structure is the same as.

$$G(\tilde{k}, \omega)_{34} = \frac{S_1(\tilde{k}, \omega)(\tilde{\omega}^2 - \tilde{\epsilon}_2(\tilde{k})^2)}{(\tilde{\omega}^2 - \tilde{\epsilon}_2(\tilde{k})^2)((\tilde{\epsilon}_1(\tilde{k}) + \Sigma_1(\tilde{k}, \omega))^2 + S_1(\tilde{k}, \omega)^2 - \tilde{\omega}^2) + 2t^2(\tilde{\omega}^2 + \tilde{\epsilon}_2(\tilde{k})\tilde{\epsilon}_1(\tilde{k}) + \Sigma_1(\tilde{k}, \omega))) - t^4}$$

(A13)
in Eq. (A14), and we have:

\[
\langle c_{\vec{k}21}^+ c_{-\vec{k}21}^\dagger \rangle \simeq \frac{t^2 S_1(\vec{k}; \omega)}{2E_1(\vec{k})(E_1(\vec{k})^2 - \epsilon_2(\vec{k})^2)}. \tag{A15}
\]

Note that it is straightforward to obtain full analytic results without this small \( t \) (tunneling strength) approximation, but the results are less illuminating. We stick with the Hartree and small \( t \) approximations in this Appendix A to illustrate the main idea.

From Eq. (A15) the rough estimate gives the second layer superconductivity gap magnitude \(|\Delta_2|\):

\[
|\Delta_2| \simeq k_B T'_{\tilde{c}_2} \leq \frac{t^2}{|\epsilon_2^2 - E_1^2|} |\Delta_1| \simeq \frac{t^2 k_B T_{\tilde{c}_2}}{|\epsilon_2^2 - E_1^2|} \tag{A16}
\]

Here we use \( |\Delta_2| \leq |\sum_k V_1 \langle c_{\vec{k}21}^+ c_{-\vec{k}21}^\dagger \rangle | \), and \( E_i \) and \( \epsilon_i \) as the average of \( E_i(\vec{k}) \) and \( \epsilon_i(\vec{k}) \) in momentum space as a rough estimate. From this estimate, we know for \( \epsilon_2(\vec{k}) \) very different from \( \epsilon_1(\vec{k}) \) ("mismatched" Fermi surface) the denominator in Eq. (A16) increases, giving rise to smaller gap magnitude as expected. The gap symmetry of the second layer is determined by both the first layer gap symmetry and the Fermi surfaces from both layers. We do not use this estimate in the main text, but Eq. (A16) gives naive intuitions why the mismatched Fermi surfaces give smaller proximity induced pairing amplitude.

2. Two bands or three layers

For two metallic bands or two metallic layers we follow the same definition of generalized Green’s function and extend the 4 \( \times \) 4 bases to 6 \( \times \) 6 ones to accommodate this extra degree of freedom. For \( V(q) = 0 \) we have the retarded Green’s function \( G_0(\vec{k}, \omega) \) taking the form:

\[
G_0(\vec{k}, \omega) = \begin{pmatrix}
\omega - \tilde{\epsilon}_1(\vec{k}) + i\eta & 0 & t_{12} & 0 & t_{13} & 0 \\
0 & \omega + \tilde{\epsilon}_1(\vec{k}) + i\eta & 0 & -t_{12} & 0 & -t_{13} \\
t_{12} & 0 & \omega - \tilde{\epsilon}_2(\vec{k}) + i\eta & 0 & t_{23} & 0 \\
0 & -t_{12} & 0 & \omega + \tilde{\epsilon}_2(\vec{k}) + i\eta & 0 & -t_{23} \\
t_{13} & 0 & t_{23} & 0 & \omega - \tilde{\epsilon}_3(\vec{k}) + i\eta & 0 \\
0 & -t_{13} & 0 & -t_{23} & 0 & \omega + \tilde{\epsilon}_3(\vec{k}) + i\eta
\end{pmatrix}^{-1} \tag{A17}
\]

For \( \Sigma(\vec{k}, \omega) \approx \hat{\Sigma}_H \) as in previous case we have

\[
G(\vec{k}, \omega)_{12} = S_1(\vec{k}, \omega) \left( t_{23}^4 - 2t_{23}^3(\tilde{\omega} + \tilde{\epsilon}_2(\vec{k})\tilde{\epsilon}_3(\vec{k})) + (\tilde{\omega} - \tilde{\epsilon}_2(\vec{k})^2)(\tilde{\omega} - \tilde{\epsilon}_3(\vec{k})^2) \right) / Dc(\vec{k}, \omega)
\]

\[
G(\vec{k}, \omega)_{34} = S_1(\vec{k}, \omega) \left( (t_{13}t_{23} - t_{12} \tilde{\omega} - \tilde{\epsilon}_3(\vec{k}))(t_{13}t_{23} + t_{12} \tilde{\omega} - \tilde{\epsilon}_3(\vec{k})) \right) / Dc(\vec{k}, \omega)
\]

\[
G(\vec{k}, \omega)_{56} = S_1(\vec{k}, \omega) \left( (t_{13}t_{23} - t_{13} \tilde{\omega} - \tilde{\epsilon}_2(\vec{k}))(t_{13}t_{23} + t_{13} \tilde{\omega} + \tilde{\epsilon}_2(\vec{k})) \right) / Dc(\vec{k}, \omega)
\]

\[
Dc(\vec{k}, \omega) \equiv t_{13}^4(\tilde{\epsilon}_2(\vec{k})^2 - \tilde{\omega}^2) + 4t_{13}^2t_{23}(\tilde{\omega} + \tilde{\epsilon}_2(\vec{k})\tilde{\epsilon}_3(\vec{k})) + t_{13}^4(\tilde{\epsilon}_2(\vec{k})^2 - \tilde{\omega}^2) + 2t_{13}^2(\tilde{t}_{23}^2(\tilde{\omega} - \tilde{\epsilon}_2(\vec{k})\tilde{\epsilon}_3(\vec{k}) + (\tilde{\omega}^2 - t_{13}^2)(\tilde{\epsilon}_2(\vec{k})^2 + \tilde{\epsilon}_3(\vec{k})(\tilde{\epsilon}_1(\vec{k}) + \Sigma_1(\vec{k}, \omega))))
\]

The tunneling strength \( t_{12} \) depends on the overlap integrals, i.e. the symmetry of the respective eigenstates. For the special case of \( t_{13} = 0 \) (such as the trilayer case, where there is no direct tunneling between the first superconductor layer and third metallic layer) but finite and small \( t_{12} \) and \( t_{23} \), we take the leading order in \( t_{12} \)
frequency integral and obtain:

\[
\langle \hat{c}^\dagger_{\mathbf{k},1} \hat{c}^\dagger_{-\mathbf{k},1} \rangle \simeq \frac{-S_1(\mathbf{k},\omega)}{2E_1(\mathbf{k})} \tag{A18}
\]

\[
\langle \hat{c}^\dagger_{\mathbf{k},1} \hat{c}^\dagger_{\mathbf{k},2} \rangle \simeq \frac{t_{22}^2 S_1(\mathbf{k},\omega)}{2E_1(\mathbf{k})(E_1(\mathbf{k})^2 - \varepsilon_2(\mathbf{k})^2)} \tag{A19}
\]

\[
\langle \hat{c}^\dagger_{\mathbf{k},1} \hat{c}^\dagger_{-\mathbf{k},2} \rangle \simeq \frac{-S_1(\mathbf{k},\omega)t_{22}^2 t_{23}^2}{2E_1(\mathbf{k})(E_1(\mathbf{k})^2 - \varepsilon_2(\mathbf{k})^2)(E_1(\mathbf{k})^2 - \varepsilon_3(\mathbf{k})^2)} \tag{A20}
\]

Similar to the bilayer case, we obtain the rough estimate for proximity induced gap magnitude on the third layer: \( |\Delta_3| \leq |\sum_{\mathbf{k}} V_1 \langle \hat{c}^\dagger_{\mathbf{k},1} \hat{c}^\dagger_{-\mathbf{k},1} \rangle \simeq \frac{t_{22}^2}{|t_{22}^2 - t_{23}^2||E_1(\mathbf{k}) - E_3(\mathbf{k})|} |\Delta_2| \simeq \frac{|t_{22}^2|}{|t_{22}^2 - t_{23}^2|} |\Delta_1| \).

The same formulation can be extended to the case of two bands in a single metallic layer. In this case, we perform the same calculations but with \( t_{23} = 0 \) and nonzero but small \( t_{12} \) and \( t_{13} \). The label \( 2 \) and \( 3 \) here denote the two bands in the metallic layer. We will not present the calculations here, but just mention that it is a straightforward extension of current formula.

### 3. Metallic layer with spin orbit interactions

For two dimensional electron gas in a symmetric quantum well, such as the heterostructure in the bilayer system discussed above, or the surface state of three dimensional topological insulator, the anisotropy or asymmetry in general leads to some type of spin orbit interactions. To include this factor, we consider a generic linear momentum dependent spin orbit coupling in our two dimensional metallic layer:

\[ H_{so} \simeq \alpha k_x \sigma_y + \beta k_y \sigma_x = \frac{1}{2}(\alpha + \beta)(k_x \sigma_y + k_y \sigma_x) + \frac{1}{2}(\alpha - \beta)(k_x \sigma_y - k_y \sigma_x) \tag{A21} \]

The term times \((\alpha + \beta)\) is named Dresshau effect, often occurring in systems lacking reflection symmetry. The other term associated with \((\alpha - \beta)\) is called Bychkov-Rashba effect which happens when inversion symmetry is broken. To explicitly incorporate the spin degree of freedom we use four component Nambu bases on a single layer: \( \Psi_{\mathbf{k},l} = (c_{\mathbf{k}l\uparrow}^\dagger \ c_{\mathbf{k}l\downarrow}^\dagger \ c_{-\mathbf{k}l\downarrow}^\dagger \ c_{-\mathbf{k}l\uparrow}^\dagger)^T \). Here \( l = 1, 2 \) denotes layer index and this basis is chosen as the basis for direct product of spin and electron hole space.

For real \( \Delta_1 \), the matrix form of the Hamiltonian describing the superconducting layer \( (H_S) \), normal metal layer \( (H_N) \), and tunneling term between the two \( H_t \), in this four component basis are:

\[ H_S = (\epsilon_1(\mathbf{k}) - \mu_1) \tau_z \sigma_0 + \Delta_1 \tau_z \sigma_0, \]

\[ H_N = (\epsilon_2(\mathbf{k}) - \mu_2) \tau_z \sigma_0 + \tau_z \sigma_0 (\alpha k_x \sigma_y + \beta k_y \sigma_x), \]

\[ H_t = t \tau_z \sigma_0. \tag{A22} \]

Note that we use \( \epsilon_2^0(\mathbf{k}) \) to denote the diagonal (in spin space) part of the \( H_N \), and \( \epsilon_2(\mathbf{k}) - \mu_2 = \epsilon_2^0(\mathbf{k}) \pm \sqrt{|\alpha k_x|^2 + |\beta k_y|^2} - \mu_2 \) is used to denote the eigenvalue of \( H_N \) as in other sections. Furthermore, in Eq. \( A22 \) we have assumed \( \Delta_1 = \Delta(\mathbf{k}) = \Delta(-\mathbf{k}) \) by placing the conventional even pairing superconductor \((s \ or \ d \ wave \ superconductor)\) on top of the metallic layer. The \( 4 \times 4 \) matrix forms of Eq. \( A22 \) are:

\[
H_S = \begin{pmatrix}
\epsilon_1(\mathbf{k}) & 0 & \Delta_1(\mathbf{k}) & 0 \\
0 & \epsilon_1(\mathbf{k}) & 0 & \Delta_1(-\mathbf{k}) \\
\Delta_1^*(\mathbf{k}) & -\epsilon_1(\mathbf{k}) & 0 & 0 \\
0 & \Delta_1^*(-\mathbf{k}) & 0 & -\epsilon_1(\mathbf{k})
\end{pmatrix}
\]

\[
H_N = \begin{pmatrix}
\epsilon_2(\mathbf{k}) & \epsilon_{so}(\mathbf{k}) & 0 & 0 \\
\epsilon_{so}(\mathbf{k})^* & \epsilon_2(\mathbf{k}) & 0 & 0 \\
0 & 0 & -\epsilon_2(\mathbf{k}) & -\epsilon_{so}(\mathbf{k}) \\
0 & 0 & -\epsilon_{so}(\mathbf{k})^* & -\epsilon_2(\mathbf{k})
\end{pmatrix}
\]

Here \( \epsilon_{so}(\mathbf{k}) \equiv \beta k_y + i \alpha k_x \). The tunneling term \( H_t \) with constant tunneling amplitude \( t \) takes the form:

\[
H_t = \begin{pmatrix}
t & 0 & 0 & 0 \\
0 & t & 0 & 0 \\
0 & 0 & -t & 0 \\
0 & 0 & 0 & -t
\end{pmatrix}
\]

This \( 4 \times 4 \) matrix for \( H_t \) connects the bases of \( \Psi_{\mathbf{k},1} \) and \( \Psi_{\mathbf{k},2} \) with the assumption of momentum conservation. In this paper \( \Delta_1(-\mathbf{k}) = \Delta_1(\mathbf{k}) \) as our superconductor is either \( s \) wave or \( d \) wave type. The full Hamiltonian, given by

\[
H = \begin{pmatrix}
H_S & H_t \\
H_t^* & H_N
\end{pmatrix}
\]

is described by a \( 8 \times 8 \) matrix or in the \( (\Psi_{\mathbf{k},1}, \Psi_{\mathbf{k},2}) \) bases. Assuming \( t \) is real and denoting \( \omega = \omega + itn \) as before, the matrix element of the retarded Green’s function \( G = (\omega - H + i\eta)^{-1} \) related to second layer pairing amplitude \( A_2 \) are
This $G(\vec{k}, \omega)_{57} = -G(\vec{k}, \omega)_{68}$ has to do with the fact that there is no $\sigma_z$ term in this spin orbit metallic Hamiltonian (which is not the case in the main text). Following the same Hartree and small $t$ approximations as in Appendix A1 we get

$$
\langle \epsilon_{k_{2\uparrow}} \epsilon_{k_{2\downarrow}} \rangle \simeq -\frac{\Delta(\vec{k})t^2(\vert \alpha k_x \vert^2 + \vert \beta k_y \vert^2 + \tilde{\epsilon}_2(\vec{k})^2 - E_1(\vec{k})^2)}{2E_1(\vec{k}) (E_1(\vec{k})^2 - \vert \alpha k_x \vert^2 - \vert \beta k_y \vert^2)^2 - 2(E_1(\vec{k})^2 + \vert \alpha k_x \vert^2 + \vert \beta k_y \vert^2)\tilde{\epsilon}_2(\vec{k})^2 + \tilde{\epsilon}_2(\vec{k})^4)}
$$

$$
\langle \epsilon_{k_{2\uparrow}} \epsilon_{k_{2\downarrow}} \rangle \simeq \frac{\Delta(\vec{k})t^2(\alpha k_x + \beta k_y)\tilde{\epsilon}_2(\vec{k})}{E_1(\vec{k}) (E_1(\vec{k})^2 - \vert \alpha k_x \vert^2 - \vert \beta k_y \vert^2)^2 - 2(E_1(\vec{k})^2 + \vert \alpha k_x \vert^2 + \vert \beta k_y \vert^2)\tilde{\epsilon}_2(\vec{k})^2 + \tilde{\epsilon}_2(\vec{k})^4)}
$$

| $\alpha, \beta$ | $A_{\alpha}$ | $A_{\beta}$ | $\Delta_i$ |
|---------------|-------------|-------------|------------|
| (1, 1)        | 0.07782     | -0.07747i   | 0.92121    |
| ($\frac{1}{2}, \pm \frac{1}{2}$) | 0.09534 | -0.08590i | 0.92104 |
| (0, 0)        | 0.14964     | 0.0         | 0.92181    |

Table II. Pairing amplitude for various $\alpha, \beta$ with $\mu_2 = 1.5$, $t = 0.1$, $V_1 = -0.07$, and 160 $\times$ 160 k-points is used in momentum summation. $\epsilon_2^{(0)}(\vec{k}) = 0$ for the top two rows and $\epsilon_2(\vec{k}) = \sqrt{k_x^2 + k_y^2}$ for the bottom row. Pairing amplitude $A_{2p+i\sigma}$ is related to $A_{\alpha_2+i\sigma}$ listed in the table by $A_{2p+i\sigma} = A_{2\alpha+i\sigma}(\alpha \sin(k_x) + i\beta \sin(k_y))$. From the numerator of Eq. (A26) and Eq. (A25), it is clear that the leading pairing amplitude of spin triplet $\left(\uparrow\downarrow \text{ or } \downarrow\uparrow\right)$ is of $p \pm ip$ form, and that of spin singlet is of s or d -wave form (depending on the source superconductor, i.e. the symmetry of $\Delta_1(\vec{k})$). This is indeed verified numerically as shown in Table II and Table III in which we use s-wave superconductor as first layer with dispersion $\epsilon_1(\vec{k}) = \cos(k_x) + \cos(k_y) + 1$. In this computation we have solved the superconducting gap equation self consistently, and before coupling the metallic layer the gap magnitude of the s wave superconductor is 1 by choosing $V_1 = -0.07$.

Eq. (A20) also illustrates why the d-wave pairing in the superconductor change the pairing orientations as the different signs of d wave pairing gap modifies the relative sign along $k_x$ and $k_y$ directions. Note that there is no p-wave pairing in this spin triplet sector ($\uparrow\downarrow$ or $\downarrow\uparrow$) but only $p \pm ip$ pairing in the $\left(\uparrow\uparrow \text{ or } \downarrow\downarrow\right)$. This has to do with the lack of $\sigma_z$ terms in the model Hamiltonian Eq. (A22). By introducing Zeeman field terms we can also generate the $p$-wave pairing in this $\left(\uparrow\downarrow \text{ or } \downarrow\uparrow\right)$ spin sector as shown in the discussion of warping terms in Section II.

### Appendix B: Comparison between bilayer and trilayer system

Here we compare the proximity induced pairing amplitudes of the bottom metallic layer in the bilayer and trilayer system. The bottom metallic layers of both sys-
tems have the same linear dispersion $E_N = |\vec{k}|$ and chemical potential $\mu_N = 1.5$. For both bilayer and trilayer systems, we choose the same dispersion $E_{SC} = \cos k_x + \cos k_y$ and chemical potential $\mu_{SC} = -1$ in the superconducting layer. The top and bottom Fermi surfaces are chosen to take different forms to highlight the issues of mismatched Fermi surfaces, leading to poor superconducting proximity effect, in general, compared with the matched ones. An intriguing question is whether the middle metallic layer could serve as a good bridging layer to enhance this proximity induced pairing amplitude in the bottom layer, compared with the direct coupling in the bilayer system.

FIG. 4. $E_N = |\vec{k}|$ and $E_{SC} = \cos k_x + \cos k_y$ with $\mu_N = 1.5$ and $\mu_{SC} = -1.0$. $V_{sc}$ = 0.08, 40 x 40 k-points. (a). Fermi Surface of the bilayer system (b). Fermi Surface of the trilayer system for $E_{b1} = 4 \cos k_x \cos k_y + 2 \cos 2k_x + 2 \cos 2k_y$ with $\mu_{b1} = 0.0$. (c). Fermi Surface of the trilayer system for $E_{b2} = (\cos k_x + \cos k_y - 1.05)(\cos k_x + \cos k_y + 1.05)$ with $\mu_{b2} = 0.0$. (Green for the SC layer, red for the N layer and blue for the bridge layer) (d). Pairing amplitude of the bilayer and trilayer systems.

The tunneling strength of the bilayer and trilayer systems are labeled by $t_b$ and $t_1$, assuming the tunneling strengths to be identical in the trilayer system for the ease of scaling argument. Compared to the bilayer system, electrons in the trilayer system have to hop twice from the top superconducting layer to the bottom metallic layer. To compare the results of the trilayer systems with those of the bilayer system, we label the effective hopping term of the trilayer system as $t'_b$ and that of bilayer system as $t_b$ (Here we choose $\Delta_0 = 1$ so the dimensionless quantity is $(t'_b/\Delta_0)^2 = t_b^2$. Same for $t_b/\Delta_0 = t_b$).

We then compare the pairing amplitudes of $N_1$ and $N_2$ as a function of effective hopping terms $t_b$ and $t'_b$ respectively.

![Proximity Effect Graph](image)

(c) Pairing amplitude vs. normalized hopping

FIG. 5. $E_N = |\vec{k}|$ and $E_{SC} = \cos k_x + \cos k_y$ with $\mu_N = 1.5$ and $\mu_{SC} = -1.0$. $V_{sc}$ = 0.08, 40 x 40 k-points. (a). Fermi Surface of the bilayer system (b). Fermi Surface of the trilayer system for $E_{b3} = |\vec{k}|$ with $\mu_{b3} = 2.2$. (Green for the SC layer, red for the N layer and blue for the bridge layer) (c). Pairing amplitude of the bilayer and trilayer systems.

To test this bridging layer idea, we choose two special energy dispersions for the middle metallic layer $E_{b1} = 4 \cos k_x \cos k_y + 2 \cos 2k_x + 2 \cos 2k_y$ and $E_{b2} = (\cos k_x + \cos k_y - 1.05)(\cos k_x + \cos k_y + 1.05)$. The chemical potentials $\mu_{b1} = \mu_{b2} = 0$ are chosen such that the Fermi surface covering both that of the top and bottom layer, as shown in Fig.4(b) and Fig.4(c). We plot the pairing amplitude strengths $A_2$ as a function of the effective hopping terms $t_b$ and $t'_b$ for bilayer and trilayer systems in Fig.4(d). As shown in Fig.4(d), for small effective hopping terms, this choice of bridging layer does enhance the pairing amplitude of the bottom metallic layer. For larger effective hopping terms, however, the bilayer system always has larger pairing amplitudes than the trilayer system regardless of the shape of middle metallic layer Fermi surface.

In contrast to the previous case where the Fermi Surface of the bridging layer matches those of the superconducting and bottom metallic layer, we further study the case where the Fermi Surface of the bridging layer lies between those of the two layers. The same dispersions are chosen for top and bottom layers while the bridging layer has a linear dispersion $E_{b3} = |\vec{k}|$ with the chemical potential $\mu_{b3} > \mu_N$ as shown in Fig.5(b). The result...
is shown in Fig. 5. In contrast to the matching of both Fermi surfaces shown in Fig. 4, the enhancement here is relatively large in terms of magnitude and the range of the effective hopping terms. However, at larger tunneling strengths, the direct coupling in the bilayer system still gives larger pairing amplitude.

All of these numerical results can be understood qualitatively from the analytic pairing amplitude derived perturbatively with Hartree approximations in Appendix A. Under the small tunneling strengths approximation the proximity induced superconductivity pairing amplitude for second and third layer in trilayer system are given in Eq. (A.19) and Eq. (A.20), which we rewrite as:

\[
\langle c_{k+}^\dagger c_{k+} \rangle \sim \frac{t_b^2\Delta_1(\hat{k})}{2E_1(\hat{k})(E_1(\hat{k})^2 - \bar{\epsilon}_b(\hat{k})^2)}
\]

\[
\langle c_{k}^\dagger c_{k} \rangle \sim \frac{-\Delta_1(\hat{k})t_b^4}{2E_1(\hat{k})(E_1(\hat{k})^2 - \bar{\epsilon}_m(\hat{k})^2)(E_1(\hat{k})^2 - \bar{\epsilon}_b(\hat{k})^2)}
\]

In above, we replace the tunneling amplitudes by the bilayer and trilayer ones. The form of the second layer pairing amplitude \(\langle c_{k+}^\dagger c_{k+} \rangle\) in Eq. (A.19) is the same as the bottom metallic layer pairing amplitude in bilayer system under this Hartree and small tunneling strength(s) approximation, and we relabel the \(\langle c_{k+}^\dagger c_{k+} \rangle\) by \(\langle c_{k+}^\dagger c_{k+} \rangle\). Within these approximations

\[
|\langle c_{k}^\dagger c_{k} \rangle| \sim |\langle c_{k+}^\dagger c_{k+} \rangle| \sim (t_b^2/E_1(\hat{k})^2 - \bar{\epsilon}_m(\hat{k})^2)|,
\]

which is in general smaller than one even if we set \(t_b^2 = t_b\). The way to make this ratio larger than one is when \(|E_1(\hat{k})| \approx |\bar{\epsilon}_m(\hat{k})|\), the so called resonant condition in the scattering theory. This condition is made when the middle layer dispersion \(\bar{\epsilon}_m(\hat{k})\) are not completely in line with the original one given by \(\bar{\epsilon}_1(\hat{k})\), but with the Bogoliubov quasi particle level \(E_1(\hat{k})\). This is why the range and magnitude of enhancement shown in Fig. 5 is greater than that in Fig. 4. At larger tunneling strength, the shift of energy level by the single particle tunneling becomes more important, and the proximity induced gap actually decreases as discussed in Appendix B. As the suppression of pairing amplitude in trilayer is twice of the bilayer, the bilayer always has greater pairing amplitude at larger tunneling strengths as shown in Fig. 4 and Fig. 5.

Knowing that adding an additional middle metallic layer in general does not help improve the proximity effect, we discuss the issues of lattice mismatch, which is quite general, but difficult to compute for incommensurate lattice ratios, for interface between different materials in the next section.

### Appendix C: Lattice mismatch issues

For different materials, the lattice sizes and shapes are usually different. Here we focus our discussions on the cases of square lattice, and the lattice mismatch discussed here means different lattice lengths. We compare the obtained pairing amplitude \(A_2\) in the metallic layer and the self consistent gap magnitude \(\Delta_1\) of the superconducting layer. For matched Fermi surfaces and lattice sizes we choose \(\epsilon_1(\hat{k}) = -\epsilon_2(\hat{k}) = \cos(k_x) + \cos(k_y), \mu_1 = -\mu_2 = -1.0, \) with 1 and 2 denoting superconducting and metallic layer and tunneling amplitude \(t = 0.1\). For mismatched lattices we choose \(\epsilon_1(\hat{k}) = \cos(3k_x) + \cos(3k_y), \mu_1 = -\mu_2 = -1.0, \) \(\epsilon_2(\hat{k}) = \cos(4k_x) + \cos(4k_y), t = 0.1\) and \(V_1 = -0.07\). Similar choice is done for the mismatched Fermi surface with parameters chosen as \(\epsilon_1(\hat{k}) = \epsilon_2(\hat{k}) = \cos(k_x) + \cos(k_y), \mu_1 = -\mu_2 = -1.0, t = 0.1, \) and \(V_1 = -0.07\). The results are listed in Table IV.

It is clear that for originally matched Fermi surfaces, the factor of mismatched lattice makes less overlapping region of Fermi levels. Therefore we shall expect the decrease in the proximity effect. For the originally mismatched Fermi surfaces, this lattice mismatch factor actually increases the percentage of overlapping Fermi levels, and possibly enhance the proximity effect compared with original identical lattices. These intuitions are consistent with what we obtained in the numerical results shown in Table IV.

| Cases     | FSM, LM | FSM, LmM | FSmM, LM | FSmM, LmM |
|-----------|---------|----------|----------|----------|
| \(A_2\)   | -0.42214 | -0.27422 | -0.13747 | -0.25523 |
| \(\Delta_1\) | 0.90649  | 0.91302  | 0.91354  | 0.91299  |

Here we treat the BSCCO as the bulk, and its superconductivity is not influenced by the contact surface with Bi$_2$Se$_3$. More rigorously this interface gap should be evaluated self-consistently, and the gap magnitude of BSCCO at the interface would be smaller than its bulk value. Considering this would further decrease the proximity induced gap at the Bi$_2$Se$_3$. Thus the gap obtained in the main text should be viewed as the theoretical upper bound.

The $d$ wave gap reads out from the DOS might be larger than its actual value as the normal state bands also mix with the spectral weight of quasiparticles.
The inclusion of bulk band decreases the pairing gap at the contact surface, but it helps enlare the effective tunneling term (from insulating to metallic) between the contact surface and the surface measured in ARPES. Large interfacial tunneling term helps maintain the magnitude of the pairing gap measured in ARPES as shown in model discussion in Appendix. Here the focus is put on whether it helps enlare the proximity induced gap at the contact surface.
Bi$_2$Se$_3$ is not superconducting at ambient pressure, but the high pressure leading to structural change does lead to superconductivity. See P. P. Kong et. al., J. Phys.: Condens. Matter 25, 362204 (2013). Also in Bi$_2$Se$_3$ made by pulsed laser deposition the Bi$_2$Se$_3$ becomes superconducting due to proximity effect from the superconducting Bi islands grown on its surface. See P. H. Le et. al., APL Materials 2, 096105 (2014). This critical value depends on the tight binding model of BSCCO we use, but the physics of hybrid gap, or coherence gap mixing with single particle gap, mentioned in the main text exists for all different models. For Ref[22] it is $t/h = 2$ and for the tight binding model used in Ref[29] it is $t/h = 1.3$. For tight binding model used in Ref[29 and 31] the critical $t/h$ is around 3. This value mainly depends on the energy dispersion of BSCCO at $\Gamma$ point in momentum space.
