CELLULARITY OF THE LOWEST TWO-SIDED IDEAL OF AN AFFINE HECKE ALGEBRA

JÉRÉMIE GUILHOT

Abstract. In this paper we show that the lowest two-sided ideal of an affine Hecke algebra is affine cellular for all choices of parameters. We explicitly describe the cellular basis and we show that the basis elements have a nice decomposition when expressed in the Kazhdan-Lusztig basis. In type A we provide a combinatorial description of this decomposition in terms of number of paths.

1. Introduction

The notion of cellular algebra was first introduced by Graham and Lehrer in [6] for finite dimensional algebras. Roughly speaking, a cellular algebra $A$ possesses a distinguished basis (possibly more than one), known as a "cellular basis", that is particularly well-adapted to studying the representation theory of $A$. Indeed, a cellular basis yields a filtration of $A$ with composition factors isomorphic to the cell modules. Further, the structure constants with respect to the cellular basis define bilinear forms on cell modules and one can show that the quotient of a cell module by the radical of this bilinear form is either 0 or irreducible. In this way, one obtains a complete set of isomorphism classes of simple modules for the given cellular algebra. Examples of cellular algebras include many finite-dimensional Hecke algebras [4].

Recently, Koenig and Xi [10] have generalized this concept to possibly infinite dimensional algebras over a principal ideal domain $k$ by introducing the notion of affine cellular algebras. In a cellular algebra, cell modules are isomorphic to matrix rings with coefficients in $k$ and twisted multiplication with respect to the bilinear form. In the affine case, they still are isomorphic to matrix rings with twisted multiplication but the matrix ring is now defined over a quotient of a polynomial ring over $k$. As in the finite dimensional case, affine cellular structure for an algebra $A$ yields a parametrisation of the irreducible $A$-modules. In their paper, Koenig and Xi have shown that extended affine Hecke algebras of type $A$ are affine cellular. In [8], it is shown that affine Hecke algebras of rank 2 are affine cellular for all generic choices of parameters.

In this paper we are concerned with extended affine Weyl groups. Let $W_e$ be an extended affine Weyl group and let $W_0$ be the associated finite Weyl group. Then it is a well-known fact that the set $c_0 := \{ w \in W_e \mid w = x w_0 y, \ell(w) = \ell(x) + \ell(w_0) + \ell(y) \}$ is a Kazhdan-Lusztig two-sided cell and that it is the lowest one with respect to a certain order on cells. We can associate to this cell a two-sided ideal $\mathcal{M}_0$ of the corresponding affine Hecke algebra (with possibly unequal parameters).

The purpose of this paper is twofold:

(1) Show that the lowest two-sided ideal $\mathcal{M}_0$ is affine cellular and explicitly construct a cellular basis; see Section 4.

Date: October 10, 2013.
(2) Study the decomposition of the previously found cellular basis in the Kazhdan-Lusztig basis; see Section 5.
It is in type $A$ that point (2) above is the nicest: we will show in section 6 that the coefficients that appear in the expression of the cellular basis when expressed in the Kazhdan-Lusztig basis can be interpreted as the number of certain kind of paths in a Weyl chamber.

2. **Affine Weyl groups and Geometric realisation**

In this paper, we fix an euclidean $\mathbb{R}$-vector space $V$ of dimension $r \geq 1$ and we denote by $\Phi$ an irreducible root system in $V$ of rank $r$: the scalar product will be denoted by $(\ ,\ ) : V \times V \to \mathbb{R}$. The dual of $V$ will be denoted by $V^*$ and $\langle\ ,\ \rangle : V \times V^* \to \mathbb{R}$ will denote the canonical pairing. If $\alpha \in \Phi$, we denote by $\alpha^\vee \in V^*$ the associated coroot (if $x \in V$, then $\langle x, \alpha^\vee \rangle = 2(x, \alpha)/(\alpha, \alpha)$) and by $\Phi^\vee$ the dual root system. We will denote by $Q$ the root lattice. We fix a positive system $\Phi^+$ and a simple system $\Delta = \{\alpha_1, \ldots, \alpha_n\} \subset \Phi^+$.

2.1. **Affine Weyl group.** For $\alpha \in \Phi^+$ and $n \in \mathbb{Z}$, we set
$$H_{\alpha,n} = \{x \in V \mid \langle x, \alpha^\vee \rangle = n\} \quad \text{and} \quad \mathcal{F} = \{H_{\alpha,n} \mid \alpha \in \Phi^+ \text{ and } n \in \mathbb{Z}\}.$$  
We will say that $H$ is of direction $\alpha$ if $H$ is of the form $H_{\alpha,k}$ for some $k \in \mathbb{Z}$ and, for $\alpha \in \Phi^+$, we denote by $\mathcal{F}_\alpha$ the set of hyperplanes of direction $\alpha$. We will say that $H$ and $H'$ are parallel if they have same directions. For $H = H_{\alpha,k}$ with $\alpha \in \Phi^+$, we set
$$H^+ := \{\lambda \in V \mid \langle \lambda, \alpha^\vee \rangle > k\} \quad \text{and} \quad H^- := \{\lambda \in V \mid \langle \lambda, \alpha^\vee \rangle < k\}.$$  

If $H \in \mathcal{F}$, we denote by $\sigma_H$ the orthogonal reflection with respect to $H$. Then the group $W_a$ generated by $\{\sigma_H \mid H \in \mathcal{F}\}$ is an affine Weyl group of type $\Phi^\vee$. Let $0_0 \in \Phi^+$ be such that $0_0^\vee$ is the highest coroot in $\Phi^\vee$. Then $W_a$ is a Coxeter group generated by $S_a := S_0 \cup \{\sigma_{0_0,1}\}$ where $S_0 := \{\sigma_{\alpha,0} \mid \alpha \in \Delta\}$. The Weyl group $W_0$ of $\Phi$ is generated by $S_0$. The translation $t_\alpha$ of vector $\alpha \in Q$ indeed lie in $W_a$ as have $\sigma_{\alpha,1} \sigma_{H_{\alpha,0}} = t_\alpha$. In fact it is a well-known fact that $W_a \simeq W_0 \ltimes Q$.

To simplify the notation we will write $\sigma_i$ instead of $\sigma_{\alpha_i,0}$ for all $1 \leq i \leq n$ and $\sigma_0$ instead of $\sigma_{\alpha_0,1}$. Then $W_0$ is generated by $S_0 := \{\sigma_1, \ldots, \sigma_n\}$ and $W_a$ is generated by $S_a := \{\sigma_0, \ldots, \sigma_n\}$.

An alcove is a connected component of the set
$$V - \bigcup_{H \in \mathcal{F}} H.$$  
Then $W_a$ acts simply transitively on the set of alcoves $\text{Alc}(\mathcal{F})$. Recall also that, if $A$ is an alcove, then its closure $\overline{A}$ is a fundamental domain for the action of $W_a$ on $V$. We denote by $A_0$ the fundamental alcove associated to $\Phi$
$$A_0 = \{x \in V \mid 0 < \langle x, \alpha \rangle < 1 \text{ for all } \alpha \in \Phi^+\}$$  
and by $\mathcal{C}^+$ the fundamental Weyl chamber
$$\mathcal{C}^+ = \{\lambda \in V \mid \langle \lambda, \alpha^\vee \rangle > 0\}.$$  
We also set $\mathcal{C}^- = \{\lambda \in V \mid \langle \lambda, \alpha^\vee \rangle < 0\} = -\mathcal{C}^+.$

The group $W_a$ acts on the set of faces (the codimension 1 facets) of alcoves. We denote by $S$ the set of $W_a$-orbits in the set of faces. If $A \in \text{Alc}(\mathcal{F})$, then the faces of $A$ is a set of representatives of $S$ since $\overline{A}$ is a fundamental domain for the action of $W_a$. If a face $f$ is contained in the orbit $s \in S$, we say that $f$ is of type $s$. To each $s \in S$ we can associate an involution $A \to sA$ of $\text{Alc}(\mathcal{F})$: the alcove $sA$ is defined to be $A\sigma_{H_s}$ where $H_s$ is the
Let us recall the classic realization of the root system of type $A$. Let $W$ be the group generated by all such involutions. Then $(W, S)$ is a Coxeter system and it is isomorphic to the affine Weyl group $W_a$. We shall regard $W$ as acting on the left of $\text{Alc}(\mathcal{F})$. The action of $W_a$ on the right and the action of $W$ on the left commute.

Let $A \in \text{Alc}(\mathcal{F})$. Then there exists a unique $w \in W$ such that $wA_0 = A$. We will freely identify $W$ with the set of alcoves $\text{Alc}(\mathcal{F})$. We set $S = \{s_0, \ldots, s_n\}$ in such a way that $s_iA_0 = A_0\sigma_i$ for all $0 \leq i \leq n$. We introduce the following notation:

- for $w \in W$, let $\sigma_w$ be the unique element of $W_a$ such that $wA_0 = A_0\sigma_w$;
- for $A \in \text{Alc}(\mathcal{F})$, let $\sigma_A$ be the unique element of $W_a$ such that $A_0\sigma_A = A$;
- for $\alpha \in Q$ let $p_\alpha$ be the unique element of $W$ such that $p_\alpha A_0 = A_0t_\alpha$.

**Remark 2.1.** (1). Let us investigate the relationship between the actions of $W_a$ and $W$. Let $w \in W$ and let $s_{i_n} \cdots s_{i_1}$ be a reduced expression of $w$. If we denote by $H_{i_k}$ the unique hyperplane separating $s_{i_k} \cdots s_{i_1}A_0$ and $s_{i_{k-1}} \cdots s_{i_1}A_0$, we see that the set of hyperplanes which separates $A_0$ and $wA_0$ is $\{H_{i_1}, \ldots, H_{i_n}\}$ and we get

$$wA_0 = s_{i_n} \cdots s_{i_1}A_0 = A_0\sigma_{H_{i_1}} \sigma_{H_{i_2}} \cdots \sigma_{H_{i_n}}.$$ 

But we also have

$$wA_0 = s_{i_n} \cdots s_{i_1}A_0 = A_0\sigma_{i_n} \sigma_{i_{n-1}} \cdots \sigma_{i_1}.$$

From there, we can show that

$$\{H_{i_1}, \ldots, H_{i_n}\} = \{H_{\alpha_{i_1,0}}, H_{\alpha_{i_2,0}}\sigma_{i_1}, H_{\alpha_{i_3,0}}\sigma_{i_2}\sigma_{i_1}, \ldots, H_{\alpha_{i_n,0}}\sigma_{i_{n-1}} \cdots \sigma_{i_1}\}.$$ 

We refer to [9, Chapter 4.5] for details.

(2). Let $A \in \text{Alc}(\mathcal{F})$. For all $\alpha \in Q$, we have

$$p_\alpha A = p_\alpha A_0\sigma_A = A_0t_\alpha\sigma_A = A_0\sigma_A t_\alpha = At_\alpha\sigma_A.$$ 

Hence $p_\alpha A$ is a translate of $A$ of vector $\alpha\sigma_A$.

**Example 2.2.** Let us recall the classic realization of the root system of type $A$. Let $E$ be a $n + 1$-dimensional $\mathbb{R}$-vector space with basis $\epsilon_i$ ($1 \leq i \leq n + 1$) and let $V$ be the $n$-dimensional subspace of $E$ define by

$$V = \{v = (v_1, \ldots, v_{n+1}) \in V \mid \sum v_i = 0\}.$$ 

Then the root system of type $A$ can be describe as follows

- Roots: $\epsilon_i - \epsilon_j$, $1 \leq i, j \leq n + 1$;
- Simple roots: $\alpha_i := \epsilon_i - \epsilon_{i+1}$ for all $1 \leq i \leq n$;
- Positive roots: $\epsilon_i - \epsilon_j = \sum_{i \leq k < j} a_k$.

When $n = 2$, the affine Weyl group $\tilde{A}_2$ has the following Dynkin diagram:

\[ \begin{array}{ccc} 
\text{root 0} & \text{root } s_1 & \text{root } s_2 \\
\text{vertex 1} & \text{vertex 2} & \text{vertex 3} 
\end{array} \]

We draw the alcoves in this type in Figure 1. In Figure 1.(A), the dashed arrows represent the root system, the gray alcove represents the fundamental alcove $A_0$, and the dashed alcoves represent the set $-\mathcal{C}^+$. In Figure 1.(B) we describe the orbits of the faces of $A_0$ under the action of the group $W_a$. The dashed faces of $A_0$ corresponds to $s_1$, the plain one to $s_2$ and the dotted one to $s_0$. Then, the unique element of $W_a$ which sends $A_0$ to $A$ is $s_1s_3s_2s_1$. 
2.2. Weight functions and $L$-weights. Let $L : W \rightarrow \mathbb{N}$ be a weight function on $W$, that is a function which satisfies $L(ww') = L(w) + L(w')$ whenever $\ell(ww') = \ell(w) + \ell(w')$ where $\ell$ denotes the usual length function and such that $L(w) = 0$ if and only if $w$ is the identity of $W$. Recall that this implies the following property: if $s, t$ are conjugate in $W$ then $L(s) = L(t)$. (Note that the length function is indeed a positive weight function.)

From now on and until the end of this paper, we will fix a positive weight function $W$.

Let $x, y \in W$. We will write $w = x \cdot y$ if and only if $w = xy$ and $\ell(w) = \ell(x) + \ell(y)$. By definition of weight functions, we see that if we have $w = x \cdot y$ then $L(w) = L(x) + L(y)$. We generalise this notation to more than two words in a straightforward fashion.

Let $H \in \mathcal{F}$ and assume that $H$ supports a face of type $t \in S$. Then, following [3], we set $L_H = L(t)$. This is well-defined since, according to [3, Lemma 2.1], if $H$ supports a face of type $s$ and $t$ then $s$ and $t$ are conjugate in $W$ and $L(s) = L(t) = L_H$. For $\alpha \in \Phi^+$ we set $L_\alpha := \max_{H \in \mathcal{F}, L_H = 0} L_H$. We then say that $H$ is of maximal weight if $L_H = L_\alpha$ where $H$ is of direction $\alpha$. The only case where two parallel hyperplanes might have different weights is type $C$. In all other cases, parallel hyperplanes have same weight and therefore all hyperplanes are of maximal weight.

Convention 2.3. In the case where $W$ is of type $\tilde{C}_r$ with Dynkin diagram

by symmetry, we may (and we will) assume that $L(s_0) \geq L(s_n)$. (Recall that $\tilde{C}_1$ is also of type $A_1$)

Let $\alpha \in \Phi^+$. We set

$$b_\alpha = \begin{cases} 1 & \text{if } L_{H_{\alpha,0}} = L_{H_{\alpha,1}} \\ 2 & \text{otherwise} \end{cases}$$

We see that $b_\alpha = 2$ only in type $C$ when $L(s_0) > L(s_n)$.

For $\lambda \in V$ we set

$$L_\lambda := \sum_{H \in \mathcal{F}, \lambda \in H} L_H.$$ 

If we denote by $W_\lambda$ the subgroup of $W$ which stabilises the set of alcoves which contains $\lambda$ in their closure, then $W_\lambda$ is a parabolic subgroup of $W$, generated by $S_\lambda := S \cap W_\lambda$ and we have $L_\lambda = L(w_\lambda)$ where $w_\lambda$ is the longest element of $W_\lambda$. Note that, by definition, we have $L_{\lambda \sigma} = L_\lambda$ for all $\sigma \in W_\lambda$. We set $\nu_L := \max_{\lambda \in V} L_\lambda$. We then say that $\lambda \in V$ is an $L$-weight if $L_\lambda = \nu_L$. We will denote by $P$ the set of all $L$-weights. With the convention above, $0$ is always a special point and $W_0$ is isomorphic to the Weyl group associated to

\begin{figure}[h]
\centering
\begin{subfigure}{0.4\textwidth}
\centering
\includegraphics[width=\textwidth]{A_0_alcove.png}
\caption{Alcove $A_0$ and $\varnothing^-$}
\end{subfigure}
\begin{subfigure}{0.4\textwidth}
\centering
\includegraphics[width=\textwidth]{Orbits_faces.png}
\caption{Orbits of faces of $A_0$}
\end{subfigure}
\caption{Roots, hyperplanes and alcoves in type $A_2$}
\end{figure}
Let $\lambda$ be an $L$-weight. A quarter with vertex $\lambda$ is a connected component of the set

$$V = \bigcup_{\lambda \in H} \lambda.$$  

**Example 2.4.** When $L = \ell$ then $L_H = 1$ for all $H \in \mathcal{F}$ and $\nu_\ell = |\Phi^+|$. Then the following are equivalent

1. $\lambda \in V$ is an $L$-weight;
2. $\lambda$ lies in the intersection of $|\Phi^+|$ hyperplanes;
3. for all $\alpha \in \Phi^+$, there exists $\alpha_\lambda \in \mathbb{Z}$ such that $\langle \lambda, \alpha \rangle = \alpha_\lambda$ (i.e. $\lambda \in H_{\alpha, \alpha_\lambda}$);
4. $\lambda$ is a weight according to the definition in Bourbaki [2, Proposition 26 and after].

We will denote by $P^+$ be the set of dominant $L$-weights, that is the set of $L$-weights which lies in the closure of the fundamental Weyl chamber $C^+$. Finally let $P^+$ be the set of fundamental $L$-weights, that is the dual basis of

$$\{b_\alpha \alpha^\vee \mid \alpha \in \Delta\} \subset \Phi^\vee.$$

**Remark 2.5.** Once again, it is clear that the notion of dominant $L$-weights and fundamental $L$-weights coincide with the usual one when $L = \ell$. In fact (once again!) the only case when the notion of weights and $L$-weights do not coincide is when $W$ is of type $\tilde{C}_r$ and $L(s_0) > L(s_n)$.

**Example 2.6.** The next figure describes the $L$-weights of $\tilde{C}_2$. The thick arrows represent the positive roots $\Phi^+$ and the gray alcoves represents the fundamental alcove. In the case $L(s_0) = L(s_n)$, all the circled points are $L$-weights. In the case $L(s_0) > L(s_n)$, only the gray points are $L$-weights.

2.3. **Extended affine Weyl groups.** The extended affine Weyl group is defined by $W_e = W_0 \ltimes P$; it acts naturally on (the right) of $V$ and on $\text{Alc}(\mathcal{F})$ but the action is no longer faithful. If we denote by $\Pi$ the stabiliser of $A_0$ in $W_e$ then we have $W_e = \Pi \ltimes W_a$. Further the group $\Pi$ is isomorphic to $P/Q$, hence abelian, and its action on $W_a$ is given by an automorphism of the Dynkin diagram; see Planches I–IX in [2]. We use the following notation. Let $\pi \in \Pi$. Since $\pi$ permutes the generators $S_\alpha$ of $W_a$, it induces a permutation of $\{0, \ldots, n\}$. We will still denote by $\pi$ this permutation so that we have $\pi.\sigma_i = \sigma_{\pi(i)}$. We write $\sigma^\pi$ for the image of $\sigma$ under $\pi$ that is

$$\sigma^\pi = \sigma_{\pi(i_1)} \cdots \sigma_{\pi(i_n)}$$

where $\sigma = \sigma_{i_1} \cdots \sigma_{i_n}$.
We have $W_e = \Pi \ltimes W_a \simeq \Pi \ltimes W$ where the action of $\Pi$ on $W$ is of course given by $\pi \cdot s_i = s_{\pi(i)}$. We would like to define two commutative and faithful (left and right) actions of $W_e$ on a set of alcoves. To this end, we introduce the set of extended alcoves, denoted by $\text{Alc}_e(\mathcal{F})$, which is the cartesian product $\Pi \times \text{Alc}(\mathcal{F})$. Then for $\pi, \pi' \in \Pi$, $w \in W$ and $\sigma \in W_a$ we set

\[
\pi' \cdot (\pi, A) = (\pi'\pi, A) \quad (\pi, A) \cdot \pi' = (\pi\pi', A_0\sigma_\pi' A)
\]

\[
w \cdot (\pi, A) = (\pi, wA) \quad (\pi, A) \cdot \sigma = (\pi, A\sigma)
\]

**Proposition 2.7.** The two actions are faithful and they commute.

**Proof.** The fact that these two actions are faithful is straightforward since the right action of $W_a$ (respectively the left action of $W$) on $\text{Alc}(\mathcal{F})$ is faithful. Let us show that they commute. First let $w = s_1 \ldots s_n \in W$ and $\sigma = \sigma_1 \ldots \sigma_n$ so that $wA_0 = A_0\sigma$. We have

\[
w^\pi A_0 = s_{\pi(1)} \ldots s_{\pi(n)} A_0 = A_0\sigma_{\pi(1)} \ldots \sigma_{\pi(n)} = A_0\pi
\]

Let $\pi, \pi_1, \pi_2 \in \Pi$, $w \in W$, $\sigma \in W_a$ and $A = A_0\sigma A \in \text{Alc}(\mathcal{F})$. We have

\[
\pi_1 w \cdot [(\pi, A) \cdot \pi_2 \sigma] = \pi_1 w \left( (\pi\pi_2, A_0\sigma_{\pi_2} A) \right) = (\pi_1 \pi\pi_2, w^\pi A_0\sigma_{\pi_2} A)
\]

and

\[
\left[ \pi_1 w \cdot (\pi, A) \right] \cdot \pi_2 \sigma = (\pi_1 \pi, w^\pi A) \cdot \pi_2 \sigma = (\pi_1 \pi, w^\pi A_0\sigma A) \cdot \pi_2 \sigma = (\pi_1 \pi, A_0\sigma_{\pi_2} A_0\sigma_{\pi_2} A) = (\pi_1 \pi\pi_2, w^\pi A_0\sigma_{\pi_2} A)
\]

hence the result. \qed

In order to simplify the notation, we will write $\pi A$ instead of $(\pi, A)$. One needs to be careful though, we do have $\pi A_0 = (\pi, A_0) = (1, A_0)\pi = A_0\pi$ but this only holds for $A_0$.

**Remark 2.8.** Each alcove in $\text{Alc}(\mathcal{F})$ can be identified with its set of vertices $\{f_0^A, \ldots, f_n^A\}$ where $f_i^A \in V$ for all $0 \leq i \leq n$. Then the action of $W_a$ on $\text{Alc}(\mathcal{F})$ is given by

\[
A \cdot \sigma = \{f_0^A, \ldots, f_n^A\} \cdot \sigma = \{f_0^A \sigma, \ldots, f_n^A \sigma\}.
\]

The action on the left is simply deduced form the right action by setting $s_i \cdot A_0 = A_0 s_i$.

In the extended setting, we identify $A_0$ with the ordered sequence $(f_0^{A_0}, \ldots, f_n^{A_0}) \in V^{n+1}$. Now $W_e$ naturally acts diagonally on $V^{n+1}$. Note that since $\pi \in \Pi$ stabilises $A_0$, it induces a permutation of the vertices of $A_0$. By labelling the vertices carefully we have $(f_0^{A_0}, \ldots, f_n^{A_0}) \cdot \pi = (f_0^{A_0}, \ldots, f_{\pi(n)}^{A_0})$. The set of extended alcoves can be identified with the orbit of $(f_0^{A_0}, \ldots, f_n^{A_0})$ under the action of $W_e$ by setting

\[
(\pi, A) = (\pi, A_0\sigma A) \mapsto A_0 \cdot \pi\sigma A
\]

The left action is then given by $\pi w \cdot (\pi' A) = \pi w A_0 \pi'\sigma A = A_0 \pi \sigma w \pi'\sigma A$.

**Example 2.9.** Let us consider the example of type $\tilde{A}_2$ as in Example 2.2. In Figure 2.

the arrows represent the fundamental weights $\omega_1$ and $\omega_2$ and the gray alcove represents the fundamental alcove $A_0$. Consider the element $\pi = t_{\omega_1}\sigma_3\sigma_2$. Then one can check that $\pi$ stabilises the alcove $A_0$ but only globally, not pointwise. Indeed the faces of $A_0$ are permuted circularly as shown on figure 2.(B).
The weight function $L$ can be extended to $W_e$ by setting $L(\pi w) = L(w)$ for all $\pi \in \Pi$ and $w \in W$. The Bruhat order can also be extended by setting $\pi w \leq \pi' w$ if and only if $\pi = \pi'$ and $w \leq w'$ where $\pi, \pi' \in \Pi$ and $w, w' \in W$.

As before, for all $\alpha \in P$, we will denote by $p_\alpha$ the unique element of $W_e$ satisfying $p_\alpha A_0 = A_0 t_\alpha$ (where the equality holds in $\text{Alc}(F)$).

**2.4. The lowest two-sided cell of an affine Weyl groups.** We will write $w_0$ for the longest element of Weyl group $(W_0, S_0)$. We define the following subset of $W_e$:

$$c_0 = \{ w \in W_e \mid w = x \cdot w_0 \cdot y, \ x, y \in W_e \}.$$  

This set is called the lowest two-sided cell of $W_e$. The reason for this terminology is that $c_0$ is a Kazhdan-Lusztig cell (we refer to Section 3 for the definition of cells) and it is the lowest one for a certain partial order. This cell has been extensively studied, see for instance [3, 7, 12, 14, 15, 16].

In this section, we give a nice description of the elements lying in $c_0$ as in [1, 15]. Recall the definition of $b_\alpha$ in section 2.2. Let $B_0$ be the subset of $\text{Alc}(F)$ which consist of all the alcoves $\pi A$ with $A \in \text{Alc}(F)$ satisfying the following property for all $\alpha \in \Delta$:

$$\forall \lambda \in A, 0 < \langle \lambda, \alpha \rangle < b_\alpha.$$  

The set $B_0$ is very closely related to the set $c_0$ as shown in the following theorem.

**Theorem 2.10.** Let $w \in c_0$. There exist unique $\tau \in P^+$ and $z, z' \in B_0$ such that $w = z \cdot p_\lambda \cdot w_0 \cdot z'^{-1}$.  

The proof of this theorem can be found in [15, Proposition 4.3]. The result is slightly different as the author consider the non-extended case when $L = \ell$ but all the main idea easily generalize to our case. Another proof of this result in the extended case can be found in [1, Proposition 3.1].

Theorem 2.10 should be understood as follows. The set $c_0$ can be decomposed into connected components:

$$c_0 = \bigcup_{z' \in B_0} N_{z'},$$  

where $N_{z'} := \{ w \in W_e \mid w = x \cdot w_0 \cdot z'^{-1}, \ x \in W_e \}$.  

In turn each connected component can be decomposed in the following way:

$$N_{z'} = \{ zp_\tau w_0 z'^{-1} \mid \tau \in P^+, z \in B_0 \}.$$  

This shows that the set $N_{z'}$ can be covered by translates of $B_0$; see Example 2.12 below.
Remark 2.11. In the above expression of $N_{z'}$, we do not need to specify that $w = z \cdot p_{\lambda} \cdot w_0 \cdot z'^{-1}$ as it is a (non-trivial) consequence of the definition of $B_0$ and $w_0$.

Example 2.12. Let $W$ be of type $\tilde{C}_2$ and let $a, b, c \in \mathbb{N}^*$ be such that $L(s_0) = a, L(s_1) = b$ and $L(s_2) = c$. By convention, we assume that $a \geq c$. In the following figures, we describe the set $B_0$, the set $c_0$ as well as each of its connected components. We need to distinguish the case $a > c$ in which $\Pi = \{1\}$ and $a = c$ in which $\Pi \simeq \mathbb{Z}/2\mathbb{Z}$.

In Figure 3.(a) and 3.(c), the black alcove is the fundamental alcove, the dark grey alcoves correspond to the alcoves $z^{-1}A_0$ for $z \in B_0$ and the light gray areas to the set $c_0$. In Figure 3.(b) and 3.(d), we represent the connected component $N_{z'}$ for $z' \in B_0$. The light grey alcoves correspond $zw_0z'^{-1}A_0$ for all $z \in B_0$ and the darker ones to $zp_{\omega_1}w_0z'^{-1}A_0$ and $zp_{\omega_2}w_0z'^{-1}A_0$ where $\omega_1$ and $\omega_2$ are the fundamental $L$-weights.

**Figure 3.** Description of $c_0$

(a) The set $c_0$ when $a > c$

(b) Connected component $N_{z'}$ of $c_0$

(c) The set $c_0$ when $a = c$

(d) Connected component $N_{z'}$ of $c_0
3. Kazhdan-Lusztig theory

In this section \(W_e = \Pi \ltimes W\) denotes an extended affine Weyl group with generating set \(S\). The extended Bruhat order and the extended weight function will be denoted by \(\leq\) and \(\ell\).

3.1. Hecke algebras and Kazhdan-Lusztig basis. Let \(A = \mathbb{C}[q, q^{-1}]\) where \(q\) is an indeterminate. Let \(\mathcal{H}\) be the Iwahori-Hecke algebra associated to \(W\), with \(A\)-basis \(\{T_w \mid w \in W_e\}\) and multiplication rule given by

\[
T_s T_w = \begin{cases} 
T_{sw}, & \text{if } \ell(sw) > \ell(w), \\
T_{sw} + (q^{L(s)} - q^{-L(s)})T_w, & \text{if } \ell(sw) < \ell(w),
\end{cases}
\]

for all \(s \in S\) and \(w \in W_e\).

Lemma 3.2. Then \(h = \sum \lambda(T_s) T_s\) for all \(\lambda \in A\).

Proof. Using this map, we obtain right handed version of the multiplication of \(\mathcal{H}^e\):

\[
T_w T_s = \begin{cases} 
T_{ws}, & \text{if } \ell(ws) > \ell(w), \\
T_{ws} + (q^{L(s)} - q^{-L(s)})T_w, & \text{if } \ell(ws) < \ell(w).
\end{cases}
\]

Remark 3.1. If we denote by \(\mathcal{H}^e\) the subalgebra of \(\mathcal{H}\) generated by \(T_s\) with \(s \in S\) then \(\mathcal{H}\) is isomorphic to the twisted tensor product \(\mathbb{Z}[\Pi] \otimes \mathcal{H}^e\) by setting \(T_{sw} \mapsto \omega \otimes T_w\). Here \(\mathbb{Z}[\Pi]\) denotes the group algebra of \(\Pi\) over \(\mathbb{Z}\) and \(\omega \in \Pi\).

We will denote by \(\overline{\cdot}\) the ring involution of \(A\) which takes \(q\) to \(q^{-1}\). This involution can be extended to a ring involution of \(\mathcal{H}\) via the formula

\[
\overline{\sum a_w T_w} = \sum \overline{a_w} T_w^{-1} \quad (a_w \in A).
\]

We set

\[
A_{<0} = q^{-1}Z[q^{-1}], \quad \mathcal{H}_{<0} = \bigoplus_{w \in W_e} A_{<0} T_w
\]

and

\[
A_{\leq 0} = Z[q^{-1}], \quad \mathcal{H}_{\leq 0} = \bigoplus_{w \in W_e} A_{\leq 0} T_w.
\]

For each \(w \in W_e\) there exists a unique element \(C_w \in \mathcal{H}\) (see [13, Theorem 5.2]) such that (1) \(\overline{C_w} = C_w\) and (2) \(C_w \equiv T_w\) mod \(\mathcal{H}_{<0}\). For any \(w \in W_e\) we set

\[
C_w = T_w + \sum_{y \in W_e} P_{y,w} T_y \quad \text{where } P_{y,w} \in A_{<0}.
\]

The coefficients \(P_{y,w}\) are called as the Kazhdan-Lusztig polynomials. It is well known ([13, §5.3]) that \(P_{y,w} = 0\) whenever \(y \not\leq w\). It follows that \(\{C_w \mid w \in W_e\}\) forms an \(A\)-basis of \(\mathcal{H}\) known as the “Kazhdan-Lusztig basis’’.

Lemma 3.2. Let \(h \in \mathcal{H}\) be such that \(\overline{h} = h\) and \(h \equiv \sum a_z T_z\) mod \(\mathcal{H}_{<0}\) where \(a_z \in \mathbb{Z}\). Then \(h = \sum a_z C_z\).

Proof. We know [13, §5.2.(e)] that if \(h' \in \mathcal{H}_{<0}\) satisfies \(\overline{h'} = h\) then \(h' = 0\). The lemma is an easy consequence of this result setting \(h' = h - \sum a_z C_z\).

Following Lusztig [13, §3.4], let us now introduce another involution of \(\mathcal{H}\) which plays a crucial role in the sequel.

Definition 3.3. There exists a unique involutive anti-isomorphism, i.e. an \(A\)-involution, \(\overline{\cdot} : \mathcal{H} \rightarrow \mathcal{H}\) which carries \(T_w\) to \(T_{w^{-1}}\).

Using this map, we obtain right handed version of the multiplication of \(\mathcal{H}^e\):

\[
T_w T_s = \begin{cases} 
T_{ws}, & \text{if } \ell(ws) > \ell(w), \\
T_{ws} + (q^{L(s)} - q^{-L(s)})T_w, & \text{if } \ell(ws) < \ell(w).
\end{cases}
\]

Further, since \(\overline{\cdot}\) sends \(\mathcal{H}_{<0}\) to itself it can be shown that [13, §5.6] that \(C_w^\alpha = C_{w^{-1}}\), from where it follows that

\[
P_{y,w} = P_{y^{-1},w^{-1}}.
\]
3.2. Kazhdan-Lusztig cells. For any \( x, y \in W_e \), we set
\[
C_x C_y = \sum_{z \in W_e} h_{x, y, z} C_z.
\]
Note that \( h_{x, y, z} = h_{y, x, z} \) and using the \( b \)-involution we have that \( h_{x, y, z} = h_{y^{-1}, x^{-1}, z^{-1}} \).

We write \( z \leftarrow y \) if one of the following condition holds:

1. \( z = \omega y \) with \( \omega \in \Pi \)
2. \( C_z \) appears with a non-zero coefficient in the expression of \( C_x C_y \) in the Kazhdan-Lusztig basis: that is, if there exists \( s \in S \) such that \( h_{s y, z} \neq 0 \).

We then denote by \( \preceq \) the transitive closure of this relation: it is known as the Kazhdan-Lusztig left pre-order \( \preceq \) on \( W_e \). We will denote by \( \sim \) equivalence relation associated to \( \preceq \) and the equivalence classes will be called left cells.

Similarly, multiplying on the right in the defining relation, we can define a pre-order \( \succeq \). Unsurprisingly, The associated equivalence relation will be denoted by \( \sim \) and the corresponding equivalence classes are called the right cells of \( W_e \). Using the antiautomorphism \( b \), we have (see [13, §8])
\[
x \preceq y \iff x^{-1} \succeq y^{-1}.
\]
Finally we will write \( x \preceq y \) if one can find a sequence \( x = x_0, x_1, ..., x_n = y \) of \( W_e \) such that for each \( 0 \leq i \leq n - 1 \) we have either \( x_i \leftarrow x_{i+1} \) or \( x_i \leftarrow x_{i+1} \). The equivalence relation associated to \( \preceq \) will be denoted by \( \sim \) and the equivalence classes are called the two-sided cells of \( W_e \).

**Example 3.4.** Let \( s \in S \) and \( w \in W_e \) be such that \( sw > w \). Then it can be shown [13, Theorem 6.6] that
\[
C_s C_w = C_{sw} + \sum_{z < w} a_z C_z \text{ where } a_z \in \mathcal{A}.
\]
Therefore if \( sw > w \) we always have \( sw \preceq w \). A straightforward generalisation of this result shows that

1. for all \( x, w \in W_e \) such that \( xw = x \cdot w \) we have \( xw \preceq w \)
2. for all \( y, w \in W_e \) such that \( wy = w \cdot y \) we have \( wy \preceq w \)
3. for all \( x, y, w \in W_e \) such that \( xwy = x \cdot w \cdot y \) we have \( xwy \preceq w \)

3.3. Lowest two-sided cell modules. Recall that \((W_0, S_0)\) denotes the Weyl group associated to \( W \), that \( w_0 \) is the longest element of \( W_0 \) and the definition of \( c_0 \):
\[
c_0 := \{ w \in W_e \mid w = x \cdot w_0 \cdot y, x, y \in W_e \}.
\]
It is a well known result that \( c_0 \) is a two-sided cell and that it is the lowest one with respect to the partial order on two-sided cells induced by \( \preceq \). In other words, for all \( y \in W_e \) and all \( w \in c_0 \) we have
\[
y \preceq w \implies y \in c_0.
\]

**Remark 3.5.** If one knows that \( c_0 \) is a two-sided cell, it is fairly easy to see why it has to be the lowest one. Let \( z \in W_e \). Let us show that there exists \( w \in c_0 \) such that \( z \geq w \).
We construct a sequence \( z = z_0, \ldots, z_n \) in the following way

1. if \( sz_i < z_i \) for all \( s \in S_0 \) then we stop and we set \( z_i = w; \)
2. if there exists \( s \in S_0 \) such that \( sz_i > z_i \) then we set \( z_{i+1} = sz_i. \)

The process finishes as \( S_0 \) generates a finite group. Further, when it finishes, say for \( z_n \), then \( sz_n < z_n \) for all \( s \in S_0 \), that is \( z_n = w_0 z \) and it is easy to see that by construction we have \( z_n = w_0 z \). It follows that \( z \geq w \). Now this implies that \( c_0 \) is the lowest two-sided cell. Indeed let \( z \in W_e \) be such that \( z \leq w \) and \( \in c_0 \). Then we can construct \( z_n \in c_0 \) such that \( z_n \leq z \leq w \) which implies \( z_n \sim z \sim w \) as both \( z_n \) and \( w \) lies in \( c_0 \).
Relation 3.4 shows that the $\mathcal{A}$-module $\mathcal{M}_0 := \langle C_w \mid w \in c_0 \rangle_{\mathcal{A}}$ is a two-sided ideal. By definition of the pre-order $\leq_{\mathcal{M}_0}$, we have for all $h, h' \in \mathcal{H}$ and $w \in c_0$:

$$hC_wh' = \sum_{y \leq_{\mathcal{M}_0} w} C_y$$

which lies in $\mathcal{M}_0$.

Recall the definition of $\mathcal{B}_0$ in Section 2.4. For $y \in \mathcal{B}^{-1}_0$ we set

$$N_y = \{w \in W \mid w = w_0 y, x \in X_0\} \quad \text{and} \quad \mathcal{M}_y = \langle C_w \mid w \in N_y \rangle_{\mathcal{A}}.$$

We will show in the next section that $\mathcal{M}_y$ is a left ideal.

**Remark 3.6.** Note that the involution $\bar{\cdot}$ can be restricted to $\mathcal{M}_0$ as it sends $C_w$ to $C_{w^{-1}}$ and $c_0$ is easily seen to be stable under taking the inverse.

### 3.4. Relative Kazhdan-Lusztig polynomials

We denote by $X_0$ the set of representatives of minimal length of the left cosets of $W_0$ in $W_c$. We have

$$X_0 = \{x \in W_c \mid x w_0 = x \ast w_0\} \quad \text{and} \quad X_0^{-1} = \{x \in W_c \mid w_0 x = w_0 \ast x\}.$$  

**Theorem 3.7.** Let $y \in X_0^{-1}$. For all $x \in X_0$, there exists a unique family of polynomials $(p_{x',x})_{x' \in X_0}$ in $\mathcal{A}_{\leq 0}$ such that $p_{x',x} = 0$ whenever $x' \not\leq x$ and

$$\tilde{C}_{xw_0 y} = T_x C_{w_0 y} + \sum_{x' \in X_0} p_{x',x} T_{x'} C_{w_0 y}$$

is stable under the $\bar{\cdot}$ involution.

**Proof.** The proof of this theorem is given in [7] (see Lemma 5.5, Lemma 5.6 and Proposition 5.7). It is based on the fact that the $\mathcal{A}$-submodule

$$\mathcal{M} := \langle T_x C_{w_0 y} \mid x \in X_0 \rangle_{\mathcal{A}}$$

is a left ideal of $\mathcal{H}$ for all $y \in X_0^{-1}$. Then the construction of the polynomials $p_{x',x}$ only depends on the action of the $T_s$ on the elements $T_s C_{w_0 y}$. We show here that $\mathcal{M}$ is indeed a left ideal and we describe the action of $T_s$ on $T_x C_{w_0 y}$ as we will need it later on.

Fix $T_x C_{w_0 y} \in \mathcal{M}$ and $s \in S$. In order to show that $\mathcal{M}$ is a left ideal, it is enough to show that $T_s T_x C_{w_0 y} \in \mathcal{M}$. To simplify we will assume that $x \in W$, the case where $x = \pi x'$ with $(\pi, x) \in \Pi \times W$ is similar. According to Deodhar’s lemma (see [5, Lemma 2.1.2]), there are three cases to consider:

1. $sx \in X_0$ and $\ell(sx) > \ell(x)$. Then $T_s T_x C_{w_0 y} = T_{sx} C_{w_0 y}$.
2. $sx \in X_0$ and $\ell(sx) < \ell(x)$. Then $T_s T_x C_{w_0 y} = T_{sx} C_{w_0 y} + (q^{L(s)} - q^{-L(s)}) T_x C_{w_0 y}$.
3. $t := x^{-1} sx \in S_0$. Then $\ell(sx) = \ell(x) + 1 = \ell(xt)$. Now, since $tw_0 y < w_0 y$, we have [13, §5.5, Theorem 6.6] $T_t C_{w_0 y} = q^{L(t)} C_{w_0 y}$.

Thus, we see that

$$T_s T_x C_{w_0 y} = T_{sx} C_{w_0 y} = T_{xt} C_{w_0 y} = T_x T_t C_{w_0 y} = q^{L(t)} T_x C_{w_0 y}$$

In all cases, we do have $T_s T_x C_{w_0 y} \in \mathcal{M}$ as required.

Looking at the proof, we see that the action of $T_s$ on $\mathcal{M}$ do not depend on $y$. This means that the construction of the polynomials $p_{x',x}$ do not depend on $y$ either. As a consequence, there exists a unique family of polynomials $(p_{x',x})_{x' \in X_0}$ in $\mathcal{A}_{\leq 0}$ such that $p_{x',x} = 0$ whenever $x' \not\leq x$ and such that:

$$\tilde{C}_{xw_0 y} = T_x C_{w_0 y} + \sum_{x' \in X_0} p_{x',x} T_{x'} C_{w_0 y}$$

is stable under the bar involution for all $y \in X_0$. 

Theorem 3.8. Let \( y \in B_0^{-1} \). We have \( \tilde{C}_{xw_0y} = C_{xw_0y} \) for all \( x \in X_0 \). For all \( y \in B_0^{-1} \) the \( \mathcal{A} \)-submodule:
\[
\mathcal{M}_y = \langle C_{xw_0y} \mid x \in X_0 \rangle_{\mathcal{A}}
\]
is a left ideal.

Proof. According to the proof of [7, Proposition 5.7] we have
\[
\tilde{C}_{xw_0y} \equiv T_{xw_0y} \mod \mathcal{H}_{\leq 0}.
\]
We get that \( \tilde{C}_{xw_0y} = C_{xw_0y} \) using Lemma 5.3. Next using the previous theorem we see that
\[
\langle T_x C_{w_0y} \mid x \in X_0 \rangle_{\mathcal{A}} = \langle \tilde{C}_{xw_0y} \mid x \in X_0 \rangle
\]
hence the second part of the theorem. \( \square \)

Remark 3.9. Using the \( \mathfrak{b} \)-involution, we obtain right handed versions of all the results in this section. For instance, for all \( y \in X_0 \) and \( x \in X_0^{-1} \), there exists a unique family of polynomials \( (p_{x',y}^r)_{x' \in X_0, x' < y} \) in \( \mathcal{A}_{<0} \) such that
\[
\tilde{C}_{yw_0x} = C_{yw_0x} T_x + \sum_{x' \in X_0^{-1}} p_{x',yw_0x}^r C_{yw_0} T_x = C_{yw_0}(T_x + \sum_{x' \in X_0^{-1}} p_{x',yw_0x}^r T_{x'})
\]
is stable under the bar involution. Also, if \( y \in B_0^{-1} \), then we have \( \tilde{C}_{yw_0x} = C_{yw_0x} \) for all \( x \in X_0 \).

4. ON THE CELLULAR STRUCTURE

In this section we prove the main result of this paper, that the lowest two-sided ideal \( \mathcal{M}_0 \) of \( W_e \) is affine cellular in the sense of Koenig and C.Xi [10].

4.1. Affine cell ideal. Let \( k \) be a principal ideal domain. For a \( k \)-algebra \( A \), a \( k \)-linear anti-automorphism \( i \) of \( A \) satisfying \( i^2 = id_A \) is called a \( i \)-involution on \( A \). A quotient \( B = k[t_1, \ldots, t_r]/I \) where \( I \) is an ideal of \( k[t_1, \ldots, t_r] \) will be called an affine \( k \)-algebra.

For an affine \( k \)-algebra \( B \) with a \( k \)-involution \( \nu \), a free \( k \)-module \( V \) of finite rank and a \( k \)-bilinear form \( \varphi : V \times V \rightarrow B \), denote by \( \mathcal{A}(V, B, \varphi) \) the (possibly non-unital) algebra given as a \( k \)-module by \( V \otimes_k B \otimes_k V \), on which we impose the multiplication \((v_1 \otimes b_1 \otimes w_1)(v_2 \otimes b_2 \otimes w_2) := v_1 \otimes b_1 \varphi(w_1, v_2)b_2 \otimes w_2.\)

Remark 4.1. Let \( \Psi \) be the matrix representing the bilinear form \( \psi \) with respect to some choice of basis \( \{ v_1, \ldots, v_n \} \) of \( V \). Then the algebra \( \mathcal{A}(V, B, \varphi) \) is nothing else than a generalised matrix algebra over \( B \), that is the ordinary matrix algebra with coefficients in \( B \) in which the multiplication is twisted by \( \Psi \). Indeed we can identify an element
\[
\sum_{1 \leq i, j \leq n} v_i \otimes b_{i,j} \otimes v_j
\]
of \( \mathcal{A}(V, B, \varphi) \) with a \( n \times n \) matrix \( M = (b_{i,j})_{1 \leq i, j \leq n} \) with coefficients in \( B \). The multiplication of \( M_1, M_2 \) is then defined to be
\[
M_1 \cdot M_2 = M_1 \Psi M_2.
\]

In this paper, we will use the following definition of affine cell ideal.

Definition 4.2. [10, Proposition 2.3] Let \( k \) be a principal ideal domain, \( A \) a unitary \( k \)-algebra with a \( k \)-involution \( i \). A two-sided ideal \( J \) in \( A \) is an affine cell ideal if and only if there exists an affine \( k \)-algebra \( B \) with a \( k \)-involution \( \nu \), a free \( k \)-module \( V \) of finite rank and a bilinear form \( \varphi : V \otimes V \rightarrow B \), and an \( A \)-\( A \)-bimodule structure on \( V \otimes_k B \otimes_k V \), such that \( J \cong \mathcal{A}(V, B, \varphi) \) as an algebra and as an \( A \)-\( A \)-bimodule, and such that under this isomorphism the \( k \)-involution \( i \) restricted to \( J \) corresponds to the \( k \)-involution given by \( v \otimes b \otimes w \mapsto w \otimes \nu(b) \otimes v. \)
An algebra $A$ is then affine cellular if one can find a chain of two-sided ideals $0 = J_0 \subset J_1 \subset J_2 \subset \cdots \subset J_n = A$, such that each subquotient $J_i/J_{i-1}$ is an affine cell ideal in $A/J_{i-1}$. Then $J_i/J_{i-1}$ is isomorphic to $\mathcal{H}(V_i, B_i, \varphi_i)$ for some finite-dimensional vector space $V_i$, a commutative $k$-algebra $B_i$ and a bilinear form $\varphi_i : V_i \times V_i \rightarrow B_i$. Let $(\phi^j_{\nu})$ be the matrix representing the bilinear form $\phi$ with respect to some choice of basis of $V_i$. Then Koenig and Xi obtain a parametrisation of simple modules of an affine cellular algebra by establishing a bijection between isomorphism classes of simple $A$-modules and the set

$$\{(j, m) \mid 1 \leq j \leq n, m \in \text{MaxSpec}(B_j)\}$$

where $\text{MaxSpec}(B_j)$ denotes the maximal ideal spectrum of $B_j$.

**Remark 4.3.** The notion of affine cellularity should really be understood as a generalisation of cellularity for finite dimensional algebra as defined by Graham and Lehrer in [6]. In fact, we obtain the definition of cellularity for finite dimensional algebras by setting $B = k$ in the above definition. We refer to [11] for details.

4.2. **The elements $P$.** We now introduce the $P$-elements, which are crucial ingredients for the definition of the cellular basis. Recall the definition of the polynomials $p_{x,x'} \in \mathcal{A}$ for $x, x' \in X_0$ in Section 3.4. We (have) set for all $z \in B_0$ and $y \in B_0^{-1}$

$$N_y := \{zw_0y \mid x \in X_0\} \quad \mathcal{M}_y := \langle C_w \mid w \in N_y \rangle_{\mathcal{A}}$$

$$N^y := \{zw_0x \mid x \in X_0^{-1}\} \quad \mathcal{M}^y := \langle C_w \mid w \in N^y \rangle_{\mathcal{A}}.$$ 

We also set

$$\mathcal{M}_+ := \mathcal{M}_1 \cap \mathcal{M}^y = \langle C_{p_{x_0w_0}} \mid \tau \in P^+ \rangle_{\mathcal{A}}.$$ 

**Definition 4.4.** For $z \in B_0$ and $\omega \in P^+$ we set

$$P(z) = \sum_{x \in X_0} p_{x,z}T_x \quad \text{and} \quad P(\omega) = \sum_{x \in X_0} p_{x,\omega z}T_x$$

and

$$P_R(z^{-1}) = \sum_{x \in X_0^{-1}} p_{x,z^{-1}} T_x \quad \text{and} \quad P_R(\omega) = \sum_{x \in X_0^{-1}} p_{x,\omega^{-1}} T_x.$$ 

By definition, we see that for all $y \in B_0^{-1}$, $z \in B_0$ and $\omega \in P^+$ we have

$$P(z)C_{w_0y} = C_{zw_0y} \quad \text{and} \quad P(\omega)C_{w_0y} = C_{p_{\omega z}w_0y}$$

and

$$C_{zw_0}P_R(y) = C_{zw_0y} \quad \text{and} \quad C_{zw_0}P_R(\omega) = C_{zw_0p_{\omega^{-1}}}.$$ 

Further, we have $(P(z))^\tau = P_R(z^{-1})$ and $(P(\omega))^\tau = P_R(\omega)$.

The element $w_0$ acts on the set of roots. For instance in type $A$, if we keep the notation of Example 2.2, we have $w_0(\alpha_i) = -\alpha_{n-i+1}$ for all $i = 1, \ldots, n$. In type $B$, $C$, $D_{2n}$, $F_4$, $E_7$, $E_8$, $G$, $w_0$ simply acts as minus the identity. We refer to the tables in [2] for a precise description of this action. Then the action of $-w_0$ induces

- a permutation of $P^+$ which in turn induces an action on $P^+$;
- an automorphism of $W_0$ which sends the simple reflection with respect to $\alpha$ to the simple reflection associated to $-w_0(\alpha)$.

We will denote both the action on $P^+$ and the group automorphism by $\nu$. It can easily be shown that the group automorphism $\nu$ of $W_0$ extends to a group automorphism of $W_a$ and $W_c$ which, when non-trivial, is a diagram automorphism. In turn, we obtain an automorphism of $\mathcal{H}$ defined by $\nu(T_w) = T_{\nu(w)}$ for all $w \in W_c$. Now by definition of $\nu$ we obtain the following important equalities:

$$\omega w_0 = -w_0(\omega) \quad \text{and} \quad p_{\omega}w_0 = w_0p_{\nu(\omega)}^{-1} \quad \text{for all } \omega \in P^+.$$
**Proposition 4.5.** Let $\omega, \omega' \in P^+$. We have

1. \( P(\omega)C_{w_0} = C_{w_0}P_R(\nu(-\omega)) \);
2. \( P(\omega)P(\omega')C_{w_0} = P(\omega')P(\omega)C_{w_0} \).

**Proof.** We prove (1). For all $\omega \in P^+$ we have

\[ P(\omega)C_{w_0} = C_{p_w w_0} = C_{w_0 p_{\nu(\omega)}}^{-1} = C_{w_0}P_R(\nu(-\omega)). \]

We prove (2). First we show that $\nu$ and $b$ commutes. Indeed we have for all $w \in W_e$

\[ \nu(C_w^0) = \nu(C_w^{-1}) = C_{\nu(w)} = C_{\nu(w) - 1} = C_{\nu(w)}. \]

Next we show that $\nu \circ b$ acts as the identity on $P(\omega)P(\omega')C_{w_0}$. Since

\[ P(\omega)P(\omega')C_{w_0} = C_{w_0}P_R(-\nu(\omega))P_R(-\nu(\omega')) \]

we see that the element $P(\omega)P(\omega')C_{w_0}$ lies in $M_1 \cap M_y^2 = M_+$. Hence $P(\omega)P(\omega')C_{w_0}$ is an $A$-linear combination of elements of the form $C_{p_w w_0}$. Now we have

\[ \nu(C_{p_w w_0})^\flat = \nu(C_{w_0 p_{\nu(w)}}) = \nu(C_{p_{\nu(w)} w_0}) = C_{p_w w_0}. \]

On the one hand we have

\[ \nu(P(\omega)P(\omega')C_{w_0})^\flat = P(\omega)P(\omega')C_{w_0} \]

and on the other hand

\[ \nu(P(\omega)P(\omega')C_{w_0})^\flat = \nu(C_{w_0}P_R(-\nu(\omega))P_R(-\nu(\omega'))) \]

\[ = \nu(C_{w_0}P_R(-\nu(\omega'))P_R(-\nu(\omega))) \]

\[ = \nu(P(\nu(\omega'))P(\nu(\omega))C_{w_0}) \]

\[ = P(\omega')P(\omega)C_{w_0} \]

and the result follows. \(\square\)

**Definition 4.6.** For $\tau = \omega_1 + \omega_2 + \ldots + \omega_k \in P^+$ (with $\omega_i \in P^+$ for all $i$) we set

\[ P(\tau) = P(\omega_1)P(\omega_2) \ldots P(\omega_k) \]

and

\[ P_R(-\tau) = P_R(\omega_k)P_R(\omega_{k-1}) \ldots P_R(-\omega_1). \]

Note that since $P^+$ is an abelian group, we need part (2) of the previous proposition for the elements $P(\tau)$ to be well-defined.

**Remark 4.7.** By construction, we have

\[ P(z)C_{w_0 y} = C_{z w_0 y} \] and \( P(\omega)C_{w_0 y} = C_{p_w w_0 y} \)

for all $y \in B_0^{-1}$, $z \in B_0$ and $\omega \in P^+$. It is important to notice however that we do not have $P(\tau)C_{w_0 y} = C_{w_0 y}$. Indeed, we did not define $P(\tau)$ as $\sum_{x \in X_0} p_{x - \tau} x$. The decomposition of $P(\tau)C_{w_0 y}$ in the Kazhdan-Lusztig basis will be discussed in Section 5.

**Lemma 4.8.**

1. The set \( \{ P(\tau)C_{w_0} \mid \tau \in P^+ \} \) is an $A$-basis of $M_+$.
2. The set \( \{ P(z)P(\tau)C_{w_0 y} \mid z \in B_0, \tau \in P^+ \} \) is an $A$-basis of $M_y$ for all $y \in B_0^{-1}$.

**Proof.** (1) Since $P(\tau)C_{w_0} = C_{w_0}P_R(-\tau)$ we see that

\[ P(\tau)C_{w_0} \in M_1 \cap M_y^2 = M_+. \]

Then the result follows easily by a triangularity property:

\[ P(\tau)C_{w_0} = C_{p_w w_0} + \sum_{z < p_w w_0} A z. \]

(2) It is clear that $P(z)P(\tau)C_{w_0 y} \in M_y$ since $C_{w_0 y} \in M_y$ and $M_y$ is a left ideal. Once again, the result follows easily by a triangularity argument. \(\square\)
4.3. **Main result.** As our principal ideal domain \( k \), we choose \( \mathcal{A} \) and we set \( B \) to be the monoid algebra \( \mathcal{A}[P^+] = \{ e^\tau \mid \tau \in P^+ \} \). Note that \( B \) is isomorphic to the ring of polynomials in \( \text{Card}(P^+) \) indeterminates. The proof is similar to the one in [8]. The only difference here is that we need to introduce an involution on \( B \) defined by \( \nu e^\tau = e^{\nu(\tau)} \) where \( \nu \) is the involution introduced at the beginning of Section 4.2. It did not appear in [8] because in type \( G_2 \) and \( B_2 \), it is simply the identity.

Let \( z, z' \in B_0 \). On the one hand we have
\[
C_{w_0 z^{-1}} C_{z'^{-1} w_0} \subseteq C_{w_0 z^{-1} H} \subseteq \mathcal{M}_0^R
\]
and on the other hand
\[
C_{w_0 z^{-1}} C_{z'^{-1} w_0} \subseteq H C_{z'^{-1} w_0} \subseteq \mathcal{M}_1
\]
therefore \( C_{w_0 z^{-1}} C_{z'^{-1} w_0} \subseteq \mathcal{M}_+. \) Thus, by Lemma 4.8, we have
\[
C_{w_0 z^{-1}} C_{z'^{-1} w_0} = \sum_{\tau \in P^+} a^z z' P(\tau) C_{w_0} \text{ where } a^z z' \in \mathcal{A}.
\]

Let \( V \) be the free \( \mathcal{A} \)-module of rank \( \text{Card}(B_0) \) on basis \( \{ v_z, z \in B_0 \} \) and define the \( \mathcal{A} \)-bilinear form \( \varphi \) by
\[
\varphi : \ V \times V \rightarrow B \quad (v_z, v_{z'}) \mapsto \sum_{\tau \in P^+} a^z z' e^\tau.
\]
This defines an algebra \( A(V, B, \varphi) \cong V \otimes_\mathcal{A} B \otimes_\mathcal{A} V \) with multiplication \( \mathcal{A} \)-bilinearly extended from \( (v_z \otimes e^\tau \otimes v_{z'}) (v_{z''} \otimes e^{\tau'} \otimes v_{z''}) = v_{z''} \otimes e^{\tau'} \varphi(v_{z' j}, v_{z''}) e^\tau \otimes v_{z''} \) as in Section 4.1.

We now define a map
\[
\Phi : \ A(V, B, \varphi) \rightarrow \mathcal{H}
\]
by
\[
v_z \otimes e^\tau \otimes v_{z'^{-1}} \mapsto P(z) P(\tau) C_{w_0} P_R(z'^{-1})
\]
for basis elements \( v_z, v_{z'} \) of \( V \) and \( \tau \in P^+ \). We have
\[
P(z) P(\tau) C_{w_0} P_R(z'^{-1}) \in \mathcal{H} C_{w_0} \mathcal{H} \subseteq \sum_{\rho \leq \mathcal{A} C_{z_0}} \mathcal{A} C_z.
\]

Hence, the image of \( \Phi \) is contained in \( \mathcal{M}_0 \), the two-sided ideal associated to the lowest two-sided cell \( c_0 \).

**Theorem 4.9.** The two-sided ideal \( \mathcal{M}_0 \) is a an affine cell ideal. More precisely:

1. The map \( \Phi : \ A(V, B, \varphi) \rightarrow \mathcal{M}_0 \) is an isomorphism of \( \mathcal{A} \)-algebras.
2. Using (1) to define left and right \( \mathcal{H} \)-module structures on \( A(V, B, \varphi) \) by letting \( h \in \mathcal{H} \) act, for \( v, w \in V \) and \( b \in B \), as
\[
h(v \otimes b \otimes w) = \Phi^{-1} (h \Phi(v \otimes b \otimes w))
\]
and
\[
(v \otimes b \otimes w) h = \Phi^{-1} (\Phi(v \otimes b \otimes w) h)
\]
respectively, \( \Phi \) is an isomorphism of \( \mathcal{H} \)-\( \mathcal{H} \)-bimodules.
3. We have \( \Phi (v \otimes b \otimes w) \nu = \Phi (w \otimes \nu(b) \otimes v) \) for \( v, w \in V \) and \( b \in B \) and where \( \nu \) is the involution defined by \( \nu(e^\tau) = e^{\nu(\tau)} \).
The proof. The map $\Phi$ is $\mathcal{A}$-linear by definition. We have, for basis elements $v_{z_1}, v_{z_j}, v_{z_k}, v_{z_t}$ of $V$ and $\tau, \tau' \in P^+$,

$$\Phi(v_{z_1} \otimes e^\tau \otimes v_{z_j}) \Phi(v_{z_k} \otimes e^{\tau'} \otimes v_{z_t}) = P(z_1)P(\tau)C_{w_0}P_R(z_j^{-1})P(z_k)P(\tau')C_{w_0}P_R(z_t^{-1})$$

$$= P(z_1)P(\tau)C_{w_0}z_j^{-1}P(z_k)C_{w_0}P_R(-\tau')P_R(z_t^{-1})$$

$$= P(z_1)P(\tau)C_{w_0}z_j^{-1}C_{z_{w_0}w_0}P_R(-\tau')P_R(z_t)$$

$$= P(z_1)P(\tau)\left( \sum_{\tau \in P^+} a_j^{j, z_k} P(\tau) \right) C_{w_0}P_R(-\tau')P_R(z_t)$$

$$= P(z_1)P(\tau)\left( \sum_{\tau \in P^+} a_j^{j, z_k} P(\tau) \right) P(\tau')C_{w_0}P_R(z_t^{-1})$$

$$= \Phi(v_{z_1} \otimes e^\tau \varphi(v_{z_j}, v_{z_k})e^{\tau'} \otimes v_{z_t}).$$

So $\Phi$ is a morphism of $\mathcal{A}$-algebras. The fact that $\Phi$ is bijective follows easily from the fact that

$$P(z_1)P(\tau)C_{w_0}P_R(z_j^{-1}) = C_{z_{j\tau}, w_0z_j^{-1}} + \sum_{z < z_{j\tau}, w_0z_j^{-1}} \mathcal{A}C_z.$$ 

This completes the proof of (1). Statement (2) follows directly from the definition and the fact that $\mathcal{A}_0$ is an $\mathcal{H}-\mathcal{H}$-bimodule. We prove Claim (3). Let $v_{z_1}, v_{z_j}$ be basis elements of $V$ and $\tau \in P^+$. We have

$$\Phi(v_{z_1} \otimes e^\tau \otimes v_{z_j}) = \left( P(z_1)P(\tau)C_{w_0}P_R(z_j^{-1}) \right)^\bullet$$

$$= \left( P_R(z_j^{-1}) \right)^\bullet (C_{w_0})^\bullet (P(\tau))^\bullet (P(z_1))^\bullet$$

$$= P(z_1)C_{w_0}P_R(-\tau)P_R(z_j^{-1})$$

$$= P(z_1)P(\nu(\tau))C_{w_0}P_R(z_j^{-1})$$

$$= \Phi(v_{z_j} \otimes \nu(e^\tau) \otimes v_{z_1}).$$

Statement (3) follows from $\mathcal{A}$-linearity. \hfill \Box

5. On the cellular basis

In this section, we study the decomposition of the cellular basis in the Kazhdan-Lusztig basis. We set $B_0 := \{z_1, \ldots, z_n\}$ and for all $1 \leq i, j \leq n$ and $\tau \in P^+$. We will show that

\begin{equation}
(\ast)
\end{equation}

$$P(\tau)C_{w_0} = \sum_{\tau' \in P^+} m_{\tau'} C_{p_{\tau'}w_0}$$

where the coefficients $m_{\tau'}$ are integers. Note that, if we prove $(\ast)$ then we can deduce the expression of any element of the cellular basis in the Kazhdan-Lusztig basis using Corollary 5.4 below:

$$P(z_1)P(\tau)C_{w_0}P_R(z_j^{-1}) = P(z_1)(\sum m_{\tau'} C_{p_{\tau'}w_0})P_R(z_j^{-1}) = \sum m_{\tau'} C_{z_{i\tau}, w_0z_j^{-1}}.$$ 

Remark 5.1. In this section, it will sometime be more convenient to enumerate the elements of the lowest two-sided cell as $z_{i\lambda}w_0\lambda z_j$ with $\lambda \in P^- = -P^+$ instead of $z_{i\lambda}w_0z_j$ with $\tau \in P^+$. Indeed, these are the same since we have $p_{\tau}w_0 = w_0p_{\nu(\tau)}^{-1} = w_0p_{-\nu(\tau)}$. As much as possible in order to avoid confusion, we will use the letter $\lambda$ for negative weights and $\tau$ for positive weights.
5.1. Multiplication of the standard and the Kazhdan-Lusztig bases. For \( x, y \in W_e \), we set
\[
T_x T_y = \sum_{z \in W_e} f_{x,y,z} T_z \quad \text{where} \quad f_{x,y,z} \in \mathcal{A}.
\]

In this section, we present some results of [7, §2.3] that will be needed later on and we introduce some notation. For \( \alpha \in \Phi^+ \), we have set \( \mathcal{F}_\alpha = \{ H_{\alpha, n} \mid n \in \mathbb{Z} \} \). For \( x, y \in W \) we set
\[
H_{x, y} = \{ H \in \mathcal{F} \mid H \in H(A_0, yA_0) \cap H(yA_0, xyA_0) \}
\]
and
\[
I_{x, y} = \{ \alpha \in \Phi^+ \mid H_{x, y} \cap \mathcal{F}_\alpha \neq \emptyset \}.
\]
Finally for \( \alpha \in I_{x, y} \), let
\[
c_{x, y}(\alpha) = \max_{H \in H_{x, y} \cap \mathcal{F}_\alpha} L_H \quad \text{and} \quad c_{x, y} = \sum_{\alpha \in I_{x, y}} c_{x, y}(\alpha).
\]

Then we have the following result on the degree of the structure constants \( f_{x, y, z} \) with respect to the standard basis [7, Theorem 2.4].

**Theorem 5.2.** Let \( x, y \in W_e \). We have \( \deg(f_{x, y, z}) \leq c_{x, y} \) for all \( z \in W_e \).

**Proposition 5.3.** Let \( x, y \in X_0^{-1}, x \in X_0 \) and \( v \in W_0 \). The following holds
\[
\begin{align*}
(1) \quad & c_{x, vy} \leq L(w_0) - L(v) \quad \text{for all} \quad v \in W_0; \quad \text{if} \quad x \in B_0 \quad \text{then} \quad c_{x, vy} < L(w_0) - L(v) \\
(2) \quad & T_v C_{wvy} \equiv \sum_{i \in W_0} q^{L(v) - L(w_0)} T_i T_{vy} \mod \mathcal{H}_{\leq 0}; \\
(3) \quad & T_v C_{wvy} \in \mathcal{H}_{\leq 0}.
\end{align*}
\]

**Proof.** Fix \( v \in W_0 \). Let \( u = w_0 v^{-1} \) so that \( w_0 = uv \) v. Write \( w_0 = s_{i_m} \cdots s_{i_{m+1}} s_{i_m} \cdots s_{i_1} \) where \( u = s_{i_m} \cdots s_{i_{m+1}} \) and \( v = s_{i_m} \cdots s_{i_1} \) are reduced expression. Let \( H_{i_m, \ldots, H_{i_1}} \) (respectively \( H_{i_m, \ldots, H_{i_1}} \)) with direction \( \alpha_{i_m}, \ldots, \alpha_{i_1} \) (respectively \( \alpha_{i_m}, \ldots, \alpha_{i_1} \)) be the set of hyperplanes separating \( vyA_0 \) and \( w_0 yA_0 \) (respectively \( yA_0 \) and \( vyA_0 \)). Let \( \tau \) be the unique \( L \)-weight lying in the intersection of all the \( H_{i_k} \). Then since \( x \in X_0 \), we see that \( xvyA_0 \) lies in the quarter \( \mathcal{C} \) with vertex \( \tau \) which contains \( vyA_0 \).

Let \( 1 \leq \tau \leq m \) and let \( k \in \mathbb{Z} \) such that \( H_{i_k} = H_{\alpha_{i_k}, k} \). We will assume that \( k > 0 \), the case \( k \leq 0 \) being similar. We have \( vyA_0 \in V_{H_{i_k}} \). Now, since \( \tau \) lies in the closure of \( vP_{\tau}A_0 \) and \( \tau \in H_{i_k} \), one can see that
\[
k < \langle \mu, \alpha_{i_k} \rangle < k + 1 \quad \text{for all} \quad \mu \in vyA_0.
\]

Moreover, \( xvyA_0 \in \mathcal{C} \) implies that
\[
k < \langle \mu, \alpha_{i_k} \rangle \quad \text{for all} \quad \mu \in xvyA_0.
\]

From there, we conclude that all the hyperplanes \( H_{\alpha_{i_k}, l} \) with \( l \leq k \) do not lie in \( H(vyA_0, xvyA_0) \) and that all the hyperplanes \( H_{\alpha_{i_k}, l} \) with \( l > k \) do not lie in \( H(A_0, vyA_0) \). Thus \( \alpha_{i_k} \notin I_{x, vy} \) and we have
\[
I_{x, vy} \subset \{ \alpha_{i_{m+1}}, \ldots, \alpha_{i_n} \},
\]
which implies
\[
c_{x, vy} \leq \sum_{r=n}^{r=n+1} c_{x, vy}(\alpha_{i_r}) = L(w_0) - L(v)
\]
as required. In the case where \( x \in B_0 \), we see that
- if \( W \) is not of type \( C \) or if \( W \) is of type \( C \) and \( L(t) = L(t') \) then \( \alpha_{i_{m+1}} \notin I_{x, vy} \);
- if \( W \) is of type \( C \) and \( L(t) > L(t') \), then we may have \( \alpha_{i_{m+1}} \in I_{x, vy} \) but in this case the hyperplane of direction \( \alpha_{i_{m+1}} \) that lies in \( H_{x, vy} \) cannot be of maximal weight.
In both cases we see that
\[ c_{x,y} < \sum_{r=0}^{\infty} c_{x,r}(a_t) = L(w_0) - L(v). \]

Next we have
\[ T_x C_{w_0 y} = T_x \left( \sum_{z \in W_0} P_{z,w_0 y} T_z \right) \]
\[ = T_{xw_0 y} + \sum_{z < w_0 y} P_{z,w_0 y} T_x T_z. \]

Write \( z = y' \) where \( y' \in X_0^{-1} \) and \( v \in W_0 \) (any element of \( W_e \) can uniquely be written in this way; [5]). Then, using the recursive formula for Kazhdan-Lusztig polynomials, we see that
\[ P_{z,w_0 y} = P_{y',w_0 y} = q^{L(v) - L(w_0)} P_{w_0 y',w_0 y}. \]

Since the degree of the polynomials appearing in the expression of \( T_x T_z \) is at most \( c_{x,z} = c_{x,y'} \) and \( c_{x,y'} \leq L(w_0) - L(v) \) we see that we must have \( P_{z,w_0 y} T_x T_z \in \mathcal{H}_{z} \). More precisely, if \( w_0 y' < w_0 y \), then \( P_{w_0 y',w_0 y} \in \mathcal{A}_{z} \) and \( P_{z,w_0 y} T_x T_z \in \mathcal{H}_{z} \) in this case. Putting all this together, we get
\[ T_x C_{w_0 y} = T_{xw_0 y} + \sum_{z < w_0 y} P_{z,w_0 y} T_x T_z \]
\[ \equiv T_{xw_0 y} + \sum_{z \in W_0} P_{z,w_0 y} T_x T_z \mod \mathcal{H}_{z} \]
\[ \equiv T_{xw_0 y} + \sum_{y \in W_0} P_{y,w_0 y} T_x T_y \mod \mathcal{H}_{z} \]
\[ \equiv T_{xw_0 y} + \sum_{y \in W_0} q^{L(v) - L(w_0)} T_x T_y \mod \mathcal{H}_{z} \]

as required in (2). Statement (3) is a direct consequence of (1) and the above relation. \( \square \)

**Corollary 5.4.** For all \( z, z' \in B_0 \) and \( \tau \in P^+ \) we have
\[ P(z) C_{p,w_0} P_R(z'^{-1}) = C_{z p, w_0 z'^{-1}}. \]

**Proof.** Let \( z \in B_0 \), \( \tau \in P^+ \) and \( y \in X_0^{-1} \). We have
\[ P(z) C_{p,w_0} = \sum_{x \in X_0, x \leq z} p_{x,z} T_x C_{w_0 p_{x,z}^{-1}} y \]
\[ = T_z C_{w_0 p_{x,z}^{-1}} y + \sum_{x < z, x \in X_0} p_{x,z} T_x C_{w_0 p_{x,z}^{-1}} y \]
\[ \equiv T_{z p, w_0} \mod \mathcal{H}_{z} \]

by the proposition above and since \( T_z C_{p,w_0} \in \mathcal{H}_{z} \) and \( p_{x,z} \in \mathcal{A}_{z} \). Further, by definition, we know that \( P(z) C_{p,w_0} \) is stable under the \( \delta \)-involution, hence we get
\[ P(z) C_{p,w_0} = C_{z p, w_0}. \]

In particular we have
\[ P(z) C_{p,w_0} = C_{z p, w_0} \text{ and } C_{p,w_0} P_R(z^{-1}) = C_{p,w_0 z^{-1}} \]

the last equality being easily obtained using the \( \delta \)-involution. Putting all this together, we get
\[ P(z) C_{p,w_0} P_R(z'^{-1}) = P(z) C_{z p, w_0 z'^{-1}} = C_{z p, w_0 z'^{-1}} \]

as required. \( \square \)
Let \( x, w \in W \) and \( x = \pi_x s_N \ldots s_1 \) be a reduced expression of \( x \). We denote \( \mathcal{J}_{x,w} \) the collection of all subsets \( I = \{ i_1, \ldots, i_p \} \) such that \( 1 \leq i_1 < \ldots < i_p \leq N \) and \[
s_i \cdots s_{i_{p-1}} \cdots s_1 w < s_i \cdots s_{i_{p-1}} \cdots s_1 w.
\]
For \( I = \{ i_1, \ldots, i_p \} \in \mathcal{J}_{x,w} \) we set \( x_I = s_N \cdots s_{i_p} \cdots s_1 \). Then we have [3, Proof of Proposition 5.1]

(5.4) \[ T_x T_y = \sum_{I \in \mathcal{J}_{x,y}} \xi_I \] \[ \sum_{T_{xy}} T_{xy}, \]

Note that by definition we have \( x_I \leq x \) in the Bruhat order, therefore

\[ T_x T_y = \sum_{z \leq x} a_z T_{zy} \text{ where } a_z \in \mathcal{A}. \]

We will write

\[ T_x T_y \approx T_z T_y' \]

if and only if

\[ T_x T_y = \sum_{z \leq x} a_z T_{zy} \quad \text{and} \quad T_x T_y' = \sum_{z \leq x} a_z T_{zy'}. \]

Let \( \alpha \in \Phi^+ \) and \( \omega \in \mathbb{P}^+ \). We define the following integer:

\[ m_\alpha (\omega) := \max_{x \in [1, p_\omega]} \left| (xvA_0)_\alpha \right| \]

where \( [1, p_\omega] \) denotes the Bruhat interval from the identity to \( p_\omega \) and \( (xvA_0)_\alpha \) is the largest integer \( k \) in absolute value such that \( H_{\alpha,k} \) separates \( A_0 \) and \( xvA_0 \). It is a straightforward consequence of this definition that if \( H_{\alpha,k} \in H(A_0, xvA_0) \) for some \( x \in [1, p_\omega] \) then \(|k| \leq m_\alpha (\omega)\). We will then say that \( \lambda \in P^- \) is \( \omega \)-far away from the \( \alpha \)-wall if \( \lambda_\alpha \leq -m_\alpha \).

For \( \lambda \in P \) and \( \alpha \in \Phi \) we set \( \lambda_\alpha = (\lambda, \alpha^-) \) and \( A_\lambda := A_0 t \lambda \).

**Lemma 5.5.** Let \( \lambda \in P^- \), \( v \in W_0 \) and \( x \in [1, p_\omega] \). Then if \( H_{\alpha,k} \in H(xvA_\lambda, vA_\lambda) \) we have

\[ |k - \lambda_\alpha| \leq m_\alpha (\omega). \]

**Proof.** Translating the relation \( H_{\alpha,k} \in H(xvA_\lambda, vA_\lambda) \) by \( -\lambda \) we get that \( H_{\alpha,k-\lambda_\alpha} \in H(xvA_0, A_0) \). If \( H_{\alpha,k-\lambda_\alpha} \in H(xvA_0, A_0) \) then by definition of \( m_\alpha (\omega) \) we get that \(|k - \lambda_\alpha| \leq m_\alpha (\omega)\) as required. If \( H_{\alpha,k-\lambda_\alpha} \notin H(xvA_0, A_0) \) then \( H_{\alpha,k-\lambda_\alpha} \) must separate \( A_0 \) and \( vA_0 \). Therefore \( k - \lambda_\alpha = 0 \) and the result is obvious. \( \square \)

The end of this section is devoted to the study of product of the form \( T_{p_\omega} T_{v_\lambda} \) where \( \omega \in \mathbb{P}^+, \lambda \in P^- \) and \( v \in W_0 \).

**Proposition 5.6.** Let \( \lambda, \lambda' \in P^- \) and \( \Phi^+ = \Phi^+_c \sqcup \Phi^+_f \) be a disjoint union such that

1. \( \lambda \) and \( \lambda' \) are \( \omega \)-far away from the \( \alpha \)-wall for all \( \alpha \in \Phi^+_f \),
2. \( \lambda_\alpha = \lambda'_\alpha \) for all \( \alpha \in \Phi^+_c \).

Then \( T_{p_\omega} T_{v_\lambda} \approx T_{p_\omega} T_{v_{\lambda'}} \) for all \( v \in W_0 \).

**Proof.** Let \( p_\omega = \pi_\omega s_N \ldots s_1 \) be a reduced expression and let \( I = \{ i_1, \ldots, i_p \} \in \mathcal{J}_{p_\omega, v_\lambda} \). For \( 1 \leq t \leq p \) we set \( x_{i_t} = \tilde{s}_{i_t} \cdots \tilde{s}_{i_{t-1}} \cdots \tilde{s}_1 s_{i_t} \cdots s_1 \). Then by definition of \( \mathcal{J}_{p_\omega, v_\lambda} \) we have \( s_{i_t} x_{i_t} v_\lambda < s_{i_t} x_{i_t} v_\lambda \) for all \( t \in \{ 1, \ldots, p \} \). We will show that \( s_{i_t} x_{i_t} v_\lambda < s_{i_t} x_{i_t} v_\lambda \) for all \( t \in \{ 1, \ldots, p \} \). This is enough to prove the lemma, since this will show, by exchanging the role of \( \lambda \) and \( \lambda' \) that \( \mathcal{J}_{p_\omega, v_\lambda} = \mathcal{J}_{p_\omega, v_{\lambda'}} \) and the result will follow from 5.4.
Let $H_t := H_{\alpha_{t}, k_{t}}$ with $\alpha_{t} \in \Phi^{\pm}$ and $k_{t} \in \mathbb{Z}$ be the unique hyperplane separating $x_i v A_{\lambda}$ and $s_i x_i v A_{\lambda}$. Since $s_i x_i v p_{\lambda} < x_i v p_{\lambda}$ we have $H_t \in H(A_0, x_i v A_{\lambda})$. We denote by $H_t^t$ the translate of $H_t$ by $\lambda - \lambda'$. We set $k'_t = k_t + \lambda'_{\alpha_{t}} - \lambda_{\alpha_{t}}$ so that

$$H'_t := H_t((\lambda' - \lambda)) = H_{\alpha_{t}, k_{t} + \lambda'_{\alpha_{t}} - \lambda_{\alpha_{t}}} = H_{\alpha_{t}, k'_{t}}.$$  

Now, $s_i x_i v A_{\lambda}$ and $x_i v A_{\lambda}$ are translates by $\lambda' - \lambda$ of $s_i x_i v A_{\lambda}$ and $x_i v A_{\lambda}$ respectively, therefore we have $H'_t \in H(s_i x_i v A_{\lambda'}, x_i v A_{\lambda})$. We claim that $H'_t \in H(A_0, x_i v A_{\lambda'})$.

First of all, assume that $\alpha_{t} \in \Phi^{+}_f$, that is $\lambda$ and $\lambda'$ are $\omega$-far away from the wall. Since $s_i x_i, x_i \in [1, p_{\omega}]$ and $H_t \in H(x_i v A_{\lambda}, s_i x_i v A_{\lambda})$, $H_t$ separates $A_{\lambda}$ and one of the alcoves $x_i v A_{\lambda}$ or $s_i x_i v A_{\lambda}$, hence by the previous lemma we see that

$$\lambda_{\alpha_{t}} - m_{\alpha_{t}}(\omega) \leq k_{t} \leq \lambda_{\alpha_{t}} + m_{\alpha_{t}}(\omega) \leq 0.$$

Further we must have $s_i x_i v A_{\lambda} \in H_t^t$ and $x_i v A_{\lambda} \in H_t^t$ as $A_0$ and $s_i x_i v A_{\lambda}$ lie on the same side of $H_t$ which has to be $H_t^t$. Adding $\lambda'_{\alpha_{t}} - \lambda_{\alpha_{t}}$ throughout the previous equality, we get

$$\lambda'_{\alpha_{t}} - m_{\alpha_{t}}(\omega) \leq k'_{t} \leq \lambda'_{\alpha_{t}} + m_{\alpha_{t}}(\omega).$$

But $\lambda'$ is $\omega$-far away from the $\alpha_{t}$-wall, therefore $\lambda'_{\alpha_{t}} + m_{\alpha_{t}}(\omega) \leq 0$ and $k'_{t} \leq 0$. We have seen that $s_i x_i v A_{\lambda} \in H_t^t$ and $x_i v A_{\lambda} \in H_t^t$. Translating by $\lambda' - \lambda$, we get $s_i x_i v A'_{\lambda} \in H_t^t$ and $x_i v A'_{\lambda} \in H_t^t$. Then, as $k'_{t} \leq 0$, this implies that $H'_t \in H(x_i v A'_{\lambda}, A_0)$ as required.

Next assume that $\alpha_{t} \in \Phi^{+}_c$. In that case, we have

$$\langle x, \alpha_{t}' \rangle = \langle x', \alpha_{t}' \rangle \quad \text{for all } x \in x_i v A_{\lambda} \text{ and } x' \in x_i v A'_{\lambda},$$

and

$$\langle y, \alpha_{t}' \rangle = \langle y', \alpha_{t}' \rangle \quad \text{for all } y \in s_i x_i v A_{\lambda} \text{ and } y' \in s_i x_i v A'_{\lambda}. $$

Therefore it is easy to see that $H'_t \in H(x_i v A'_{\lambda}, A_0)$ in this case since $H_t \in H(x_i v A_{\lambda}, A_0)$.

Finally, in both cases, we have shown that $H'_t \in H(x_i v A'_{\lambda}, A_0)$. We have seen that $H'_t \in H(s_i x_i v A'_{\lambda}, x_i v A_{\lambda'})$. It follows that we have $s_i x_i v p_{\lambda'} < x_i v p_{\lambda'}$ as required to complete the proof of the lemma.

\begin{corollary}
Let $\lambda \in P^-$, $\omega \in P^+$ and $v \in W_0$. There exists $\lambda' \in P^-$ such that $0 \leq \lambda'_{\alpha} \leq m_{\alpha}$ for all $\alpha \in \Phi^+$ and such that $T_{p_{w}} T_{v p_{\lambda}} \approx T_{p_{w}} T_{v p_{\lambda'}}$.
\end{corollary}

\subsection{Decomposition of the cellular basis.}

\begin{theorem}
Let $\lambda, \lambda' \in P^-$ and $\Phi^+ = \Phi^+_f \sqcup \Phi^+_c$ be a disjoint union such that

1. $\lambda$ and $\lambda'$ are $\omega$-far away from the $\alpha$-wall for all $\alpha \in \Phi^+_f$;
2. $\lambda_{\alpha} = \lambda'_{\alpha}$ for all $\alpha \in \Phi^+_c$.

Then there exists a family $(a_{\alpha})_{\alpha \in P}$ of integers such that

1. $P(\omega)C_{w_{0}p_{\lambda}} = C_{p_{w}w_{0}p_{\lambda}} + \sum_{\alpha \in P, \lambda - \alpha \in P^-} a_{\alpha}C_{p_{w}w_{0}p_{\lambda}}$

and

2. $P(\omega)C_{w_{0}p_{\lambda'}} = C_{p_{w}w_{0}p_{\lambda'}} + \sum_{\alpha \in P, \lambda' - \alpha \in P^-} a_{\alpha}C_{p_{w}w_{0}p_{\lambda'}}$

\end{theorem}

\begin{proof}
We start by proving that

$$P(\omega)C_{w_{0}p_{\lambda}} = C_{p_{w}w_{0}p_{\lambda}} + \sum_{\alpha \in P, \lambda - \alpha \in P^-} a_{\alpha}C_{p_{w}w_{0}p_{\lambda}}$$

and

$$P(\omega)C_{w_{0}p_{\lambda'}} = C_{p_{w}w_{0}p_{\lambda'}} + \sum_{\alpha \in P, \lambda' - \alpha \in P^-} a_{\alpha}C_{p_{w}w_{0}p_{\lambda'}}$$

\end{proof}
for some integers \(a_\alpha\). We know that \(P(\omega)C_{\omega_0 P_\lambda} = P(\omega)C_{\omega_0 P_\lambda}\) hence according to Lemma 5.3, in order to prove the result it is enough to show that

\[(*) \quad P(\omega)C_{\lambda w_0} = T_{p_\omega w_0 P_\lambda} + \sum_{\alpha \in P, \lambda - \alpha \in P^{-}} a_\alpha T_{p_\omega w_0 P_\lambda} \mod \mathcal{H}_{<0}.
\]

We have

\[
P(\omega)C_{\omega_0 P_\lambda} = (T_{p_\omega} + \sum_{z \in X_0, z < p_\omega} p_{z, p_\omega} T_z)C_{\omega_0 P_\lambda} = T_{p_\omega} C_{\omega_0 P_\lambda} + \sum_{z \in X_0, z < p_\omega} p_{z, p_\omega} T_z C_{\omega_0 P_\lambda}.
\]

By Corollary 5.3, we know that \(T_z C_{\omega_0 P_\lambda} \in \mathcal{H}_{\leq 0}\) and therefore, since \(p_{z, w} \in \mathcal{A}_{<0}\) for all \(z \in X_0\), we get that \(p_{z, w} T_z C_{\omega_0 P_\lambda} \in \mathcal{H}_{<0}\). Thus

\[
T_{p_\omega} C_{\omega_0 P_\lambda} + \sum_{z \in X_0, z < p_\omega} p_{z, w} T_z C_{\omega_0 P_\lambda} = T_{p_\omega} C_{\omega_0 P_\lambda} \mod \mathcal{H}_{<0}.
\]

Again by Corollary 5.3 (3) we obtain

\[
T_{p_\omega} C_{\omega_0 P_\lambda} + \sum_{z \in [1, p_\omega]} a_z T_{z P_\lambda} \mod \mathcal{H}_{<0} \text{ where } a_z \in \mathbb{Z}.
\]

From there we see that

\[
P(\omega)C_{\lambda w_0} = T_{p_\omega w_0 P_\lambda} + \sum_{z \in [1, p_\omega]} a_z T_{z P_\lambda} \mod \mathcal{H}_{<0}.
\]

Next we have \(P(\omega)C_{\omega_0 P_\lambda} \in \mathcal{M}_+ = \langle C_{\omega_0 P_\lambda} \mid \gamma \in P^{-}\rangle_{\mathcal{A}}\). Thus, the only terms with non-zero coefficients in the above expression have to be of the form \(T_{w_0 P_\lambda}\) with \(\gamma \in P^{-}\). Hence, for all \(z \leq p_\omega\) there exists \(\gamma \in P^{-}\) such that \(z P_\lambda = w_0 P_\gamma = w_0 P_\gamma - \lambda P_\lambda = p_{\lambda - \gamma} w_0 P_\lambda\) and we get the desired expression by setting \(\alpha = p_{\lambda - \gamma}\).

Now, the fact that

\[
P(\omega)C_{\omega P_\lambda} = C_{\omega P_\lambda} + \sum_{\alpha \in P, \lambda - \alpha \in P^{-}} a_\alpha C_{\alpha P_\lambda}
\]

is a direct consequence of Proposition 5.6. Indeed the decomposition of \(P(\omega)C_{\omega P_\lambda}\) in the Kazhdan-Lusztig basis only depends on the products of the form \(T_{z P_\lambda}\) where \(v \in W_0\) and \(z \in [1, p_\omega]\). \(\square\)

As a direct corollary of this theorem, we see that the multiplication of the form \(P(\omega)C_{\omega_0 P_\lambda}\) can be determined for all \(\lambda \in P^{-}\) only by calculating the expression in the Kazhdan-Lusztig basis of all the products \(P(\omega)C_{\omega_0 P_\lambda}\) for all \(\lambda\) satisfying \(|\lambda_\alpha| \leq m_\alpha(\omega)\). Then, one can find the expression of a cellular basis element by induction by successively computing products of the form \(P(\omega)C_{\lambda P_\lambda}\).
In this section we study in more detail the decomposition of the cellular basis in the Kazhdan-Lusztig basis for affine Weyl groups of type $A$. We will see that the integer coefficients that appear in Theorem 5.8 in that case can be interpreted as the number of certain kind of paths from $0$ to $\lambda$. We will assume that $W = \langle s_0, \ldots, s_n \rangle$ is an affine Weyl group of type $\tilde{A}_n$ and that $W_{e} = \Pi \times W$ is the extended group where $\Pi = \langle \pi \rangle$ is a cyclic group of order $n$.

**Remark 6.1.** In type $A$ we have $\langle \omega, \alpha^\vee \rangle = \pm 1$ for all fundamental weight $\omega$ and all $\alpha \in \Phi$ (see [2, Plane 1]), therefore one can easily see that $m_\alpha(\omega) = 1$; see Section 5.1 for the definition of $m_\alpha(\omega)$. Also, we have $\alpha^\vee = \alpha$ for all $\alpha \in \Phi$.

6.1. **A refinement of Theorem 5.8.** Let $\omega \in \mathbf{P}^+$. We denote by $\partial(\omega)$ the orbit of $\omega$ under the action of $W_0 = \langle \sigma_0, \ldots, \sigma_n \rangle$.

**Theorem 6.2.** Let $\lambda \in P^-$ and $\omega \in \mathbf{P}^+$. We have

$$P(\omega)C_{w_0\lambda} = \sum_{\rho \in \partial(\omega), \lambda - \rho \in P^-} C_{p_\rho w_0\lambda}.$$ 

**Proof.** In view of the proof of Theorem 5.8, we know that

$$T_{p_\omega}C_{w_0\lambda} \equiv T_{p_\omega w_0\lambda} + \sum_{v \in W_0} q^{\ell(v) - \ell(w_0)} T_{p_\omega} T_{v\lambda} \mod \mathcal{H}_{<0}.$$ 

By Lemma 5.3, we need to show that

$$(*) \sum_{v \in W_0} q^{\ell(v) - \ell(w_0)} T_{p_\omega} T_{v\lambda} \equiv \sum_{\rho \in \partial(\omega), \lambda - \rho \in P^-} T_{p_\rho w_0\lambda} \mod \mathcal{H}_{<0}. $$

Let $v \in W_0$ and $u = w_0 v^{-1}$ so that $w_0 = u \cdot v$. Let $w_0 = s_{i_n} \ldots s_{i_m+i} \ldots s_{i_1}$ be a reduced expression of $w_0$ such that $u = s_{i_n} \ldots s_{i_m+1} v = s_{i_m} \ldots s_{i_1}$ (note that these are necessarily reduced expression). We will denote by $H_{i_m}, \ldots, H_{i_1}$ (respectively $H_{i_1}, \ldots, H_{i_m+1}$) the set of hyperplanes separating $v\lambda A_0$ and $w_0\lambda A_0$ (respectively $p_\lambda A_0$ and $v p_\lambda A_0$).

We have seen in the proof of Proposition 5.3, that the direction of the hyperplanes lying in $H_{p_\omega, v\lambda}$ belongs to $\{\alpha_{i_1}, \ldots, \alpha_{i_m+1}\}$ and are of the form $H_{\alpha_{i_k}, r_{i_k}}$ where $\langle \lambda, \alpha_{i_k} \rangle = \lambda_{i_k} < r_{i_k} \leq 0$. (In particular, if $\lambda_{i_k} = 0$ there are no hyperplane of direction $\alpha_{i_k}$ in $H_{p_\omega, v\lambda}$.)

In type $A$, since $\langle \omega, \alpha^\vee \rangle = 0$ or $1$ for all $\alpha \in \Phi^+$, we see that we must have

$$H_{p_\omega, v\lambda} \subset \{H_{\alpha_{i_1}, \lambda_{i_1}+1}, \ldots, H_{\alpha_{i_m+1}, \lambda_{i_m+1}+1}\}.$$ 

This set contains $\ell(w_0) - \ell(v)$ elements, thus to get $q^{\ell(v) - \ell(w_0)} T_{p_\omega} T_{v\lambda} \equiv 0 \mod \mathcal{H}_{<0}$ we need to have equality in the above inclusion.

**Remark 6.3.** If one can show that there are no hyperplane of direction $\alpha_r$ for $m+1 \leq r \leq n$ separating the alcoves $A_0$ and $v p_{\lambda} A_0$ or $p_{\omega} v p_{\lambda} A_0$ and $p_{\omega} v p_{\lambda} A_0$ then

$$q^{\ell(v) - \ell(w_0)} T_{p_\omega} T_{v\lambda} \equiv 0 \mod \mathcal{H}_{<0}.$$ 

We will make frequent use of this remark in the sequel.

Let $\Delta'$ be the subset of $\Delta$ which consists of all simple roots satisfying $\langle \omega, \alpha^\vee \rangle = 0$. Then the subgroup $W'$ of $W_0$ stabilising $p_\omega$ is generated by $S'_0 = \{s \in S \mid s A_0 = A_0 \sigma_{\alpha}, \alpha \in \Delta'\}$.

To prove the theorem, we will proceed in four steps:

**Claim 1.** If there exists $s \in S'$ such that $sv > v$ then $q^{\ell(v) - \ell(w_0)} T_{p_\omega} T_{v\lambda} \equiv 0 \mod \mathcal{H}_{<0}$. 

Claim 2. There is at most one term in the product \( T_{p_a} T_{vp_{\lambda}} \) expressed in the standard basis that can have a coefficient of degree \( \ell(w_0) - \ell(v) \).

Claim 3. If \( v \) is of maximal length in its coset \( W'v \) then \( p_\omega v = u^{-1} \cdot (p_\omega \sigma_u w_0) \).

Claim 4. If \( \lambda - \omega \sigma_u \notin P^- \) then \( q^{\ell(v) - \ell(w_0)} T_{p_a} T_{vp_{\lambda}} \equiv 0 \mod H_{<0} \).

Before giving the proofs of those claims, we show that they imply the theorem. By Claim 1 the only terms in \( \omega \sigma_u \) that can contribute \mod H_{<0} \ are those of the form \( q^{\ell(v) - \ell(w_0)} T_{p_a} T_{vp_{\lambda}} \) where \( v \in W_0 \) is of maximal length in its right cosets \( W'v \). Then, by Claim 2, each of these products contribute with at most one term. Fix \( v \) of maximal length in \( W'v \). Then

\[
T_{p_a} T_{vp_{\lambda}} = T_{p_a} T_{v} T_{p_{\lambda}} = T_{p_a} T_{u^{-1} p_{\omega \sigma_u} w_0} T_{p_{\lambda}} = T_{u^{-1} T_{p_{\omega \sigma_u} w_0} T_{p_{\lambda}}}.
\]

The last equality is true, thanks to Claim 3. The product \( T_{p_{\omega \sigma_u} w_0} T_{p_{\lambda}} \) gives a term \( T_{p_{\omega \sigma_u} w_0} T_{p_{\lambda}} \) with coefficient 1. But we have \( T_{p_{\omega \sigma_u} w_0} T_{p_{\lambda}} = T_{w_0 p_{\lambda} - \omega \sigma_u} \). So either \( \lambda - \omega \sigma \in P^- \) in which case \( p_{\lambda - \omega \sigma} \in X_0^{-1} \) and we get

\[
T_{u^{-1} T_{w_0} (p_{\lambda - \omega \sigma_u})} = T_{u^{-1} T_{w_0} T_{p_{\lambda - \omega \sigma_u}}} = q^{\ell(v) - \ell(w_0)} T_{w_0 P_{\lambda - \omega \sigma_u}}\]

and

\[
q^{\ell(v) - \ell(w_0)} T_{p_a} T_{vp_{\lambda}} \equiv T_{p_{\omega \sigma_u} w_0} T_{p_{\lambda}} \mod H_{<0}.
\]

Otherwise, \( \lambda - \omega \sigma \notin P^- \) and \( q^{\ell(v) - \ell(w_0)} T_{p_{\omega \sigma_u} w_0} T_{p_{\lambda}} \equiv 0 \mod H_{<0} \) by Claim 4.

Finally when \( v \) runs through all the maximal length right cosets representative of \( W' \) in \( W \) we see that \( u \) runs through all the minimal length left cosets representative and so \( \omega \sigma_u \) runs exactly through the orbit of \( \omega \) under the action of \( W_0 \). Hence the desired expression.

We now prove the four claims.

**Proof of the Claim 1.** If \( sv > v \) then we also have \( sv_{p_{\lambda}} > vp_{\lambda} \) and the hyperplane \( H_s \) which separates the alcoves \( vp_{\lambda} A_0 \) and \( sv_{p_{\lambda}} A_0 \) lies in \( \{ H_{i_0}, \ldots, H_{i_{m+1}} \} \) and is of the form \( H_{\alpha_k} \) for some \( m + 1 \leq k \leq n \). We have

\[
sp_{\omega} vp_{\lambda} A_0 = sv_{p_{\lambda}} A_0 t_{\omega \sigma_v} = vp_{\lambda} A_0 \sigma_H t_{\omega \sigma_v}
\]
and

\[
p_{\omega} sv_{p_{\lambda}} A_0 = p_{\omega} vp_{\lambda} A_0 \sigma_H t_{\omega \sigma_v} = vp_{\lambda} A_0 t_{\omega \sigma_v} \sigma_H.
\]

Thus \( \sigma_H t_{\omega \sigma_v} = t_{\omega \sigma_v} \sigma_H \), which implies that the vector \( \omega \sigma_v \) lies in \( H_s \), that \( \omega \sigma_v \) is orthogonal to \( \alpha_k \). As a consequence, since \( p_{\omega} (vp_{\lambda} A_0) = vp_{\lambda} A_0 t_{\omega \sigma_v} \), both alcoves \( p_{\omega} (vp_{\lambda} A_0) \) and \( vp_{\lambda} A_0 t_{\omega \sigma_v} \) lie on the same side of \( H_s \) and there can be no hyperplane of direction \( \alpha_k \) lying in \( H (vp_{\lambda} A_0, p_{\omega} vp_{\lambda} A_0) \). Therefore we have

\[
H_{p_{\omega} vp_{\lambda}} \subseteq \{ H_{\alpha_k}, \ldots, H_{\alpha_{m+1}}, \alpha_{i_{m+1}} + 1 \}
\]
and the claim follows with Remark 6.3.

**Proof of the Claim 2.** We use the notation of Section 5.1. We show that there is at most one set \( I \in \mathcal{I}_{p_a, vp_{\lambda}} \) which can give a term with a coefficient of degree \( \ell(w_0) - \ell(v) \). Let \( p_{wa} = \pi t_{j_1} \ldots t_{j_l} \) where \( \pi \in \Pi \) and \( t_{j_1} \ldots t_{j_l} \in W \) is a reduced expression. Let \( j_1 \) the smallest index such that \( t_{j_1} \ldots t_{j_l} \) \( < t_{j_1} \ldots t_{j_l} \) \( vp_{\lambda} \) and let \( H_{j_1} \) be the unique hyperplane separating the two corresponding alcoves. Note that \( H_{j_1} \in H_{p_{\omega}, vp_{\lambda}} \). We have

\[
T_{x} T_{vp_{\lambda}} = T_{t_{j_1} \ldots t_{j_l+1}} T_{t_{j_1} t_{j_2} \ldots t_{j_l} vp_{\lambda}} = T_{t_{j_1} \ldots t_{j_l+1}} T_{j_1 \ldots t_{j_l} vp_{\lambda}} + (q - q^{-1}) T_{t_{j_1} \ldots t_{j_l+1}} T_{j_1 \ldots t_{j_l} vp_{\lambda}}
\]
Firstly we see that \( H_{t_1 \ldots t_{j_1+1} \ldots t_1 vp_\lambda} = H_{p_\omega vp_\tau} - \{H_{j_1}\}. \) But \( H_{p_\omega vp_\lambda} \) only contains one hyperplane of direction \( \alpha_{j_1} \), hence there are no hyperplane of direction \( \alpha_{j_1} \) in \( H_{x vp_\tau} - \{H_{j_1}\} \) and we have

\[
I_{t_k \ldots t_{j_1+1} \ldots t_1 vp_\lambda} = I_{p_\omega vp_\lambda} - \{\alpha_{j_1}\}.
\]

By Theorem 5.2, the maximal degree appearing in the coefficients in \( T_{t_k \ldots t_{j_1+1} I_{t_1 \ldots t_1 vp_\lambda}} \) is \( \ell(w_0) - \ell(v) - 1 \).

Secondly, we can see that the set \( \mathcal{H} \) of hyperplanes separating the alcoves

\[
t_n \ldots t_{j_1} \ldots t_1 vp_\lambda A_0 = t_n \ldots t_{j_1} \ldots t_1 vp_\lambda A_0 \sigma H_{j_1}
\]

and

\[
t_{j_1} \ldots t_1 vp_\lambda A_0 = t_{j_1} \ldots t_1 vp_\lambda A_0 \sigma H_{j_1}
\]

is included in \( H_{p_\omega vp_\lambda} \cdot \sigma H_{j_1} - \{H_{j_1}\} \) and this set contains at most \( \ell(w_0) - \ell(v) - 1 \) elements. But we have

\[
H_{t_k \ldots t_{j_1+1} I_{t_1 \ldots t_1 vp_\lambda} \subset \mathcal{H}}
\]

hence if \( \mathcal{H} \) contains strictly less than \( \ell(w_0) - \ell(v) - 1 \) we cannot have a term of degree \( \ell(w_0) - \ell(v) - 1 \) in \( T_{t_k \ldots t_{j_1+1} I_{t_1 \ldots t_1 vp_\lambda}} \).

By induction, we construct a set \( I = \{j_1, \ldots, j_k\} \) with \( k \leq \ell(w_0) - \ell(v) \). (For instance \( j_2 \) is the smallest integer such that \( t_{j_2} \ldots t_{j_1} \ldots t_1 vp_\lambda < t_{j_2} \ldots t_{j_1} \ldots t_1 vp_\lambda \).) If we have \( k = \ell(w_0) - \ell(v) \), then the term corresponding to \( I \) in the product \( T_{p_\omega T_{vp_\lambda}} \) has a coefficient of degree \( \ell(w_0) - \ell(v) \) otherwise there are none.

**Proof of the Claim 3.** The equality \( p_\omega v = p_\omega u^{-1} w_0 = u^{-1} p_\omega v_0 \) is clear. Let \( n(\sigma_u^{-1}) := \{\alpha \in \Phi^+ | \alpha \sigma_u^{-1} \in \Phi^-\} \). It is a well known fact that \( n(\sigma_u^{-1}) = \ell(u) \). We define the following subset of \( \Phi^+ \):

\[
\mathcal{P}_0 = \{\alpha \in \Phi^+ | (\omega \sigma_u, \alpha) = 0\}
\]

\[
\mathcal{P}_< = \{\alpha \in \Phi^+ | (\omega \sigma_u, \alpha) < 0\}
\]

\[
\mathcal{P}_> = \{\alpha \in \Phi^+ | (\omega \sigma_u, \alpha) > 0\}
\]

Note that, if \( \alpha \in n(\sigma_u) \), then \( (\omega \sigma_u, \alpha) = (\omega, \alpha \sigma_u^{-1}) \leq 0 \) since \( \omega \in \Phi^+ \). On the other hand, if \( \alpha \sigma_u \in \Phi^+ \) then \( (\omega \sigma_u, \alpha) = (\omega, \alpha \sigma_u^{-1}) \geq 0 \). Therefore we see that \( \mathcal{P}_\leq \subset n(\sigma_u^{-1}) \). Assume that there exists \( \alpha \in n(\sigma_u^{-1}) \) such that \( (\omega \sigma_u, \alpha) = (\omega, \alpha \sigma_u^{-1}) = 0 \). Then \( \alpha \sigma_u^{-1} \in \Phi' \), the root system generated by the simple system \( \Delta' \). Further, since \( \alpha \sigma_u^{-1} \in \Phi^- \), we have that \( \alpha \sigma_u \in \Phi'^- \), hence we can write

\[
\alpha \sigma_u^{-1} = \sum_{\gamma \in \Delta'} a_\gamma \gamma \text{ where } a_\gamma \leq 0
\]

But then we obtain that

\[
\alpha = \sum_{\gamma \in \Delta'} a_\gamma \gamma \sigma_u \text{ where } a_\gamma \leq 0.
\]

Since \( v \) is of maximal length in its coset, we can check that \( u \) is of minimal length in its right coset with respect to \( W' \), that is \( u s > u \) for all \( s \in S' \). Therefore, \( \gamma \sigma_u \) is a positive root for all \( \gamma \in \Delta' \) and the last equality is a contradiction with the fact \( \alpha \in \Phi^+ \). We have proved that \( \mathcal{P}_\leq = n(\sigma_u^{-1}) \).
Next, since the length of an element is equal to the number of hyperplanes separating the corresponding alcoves and since \( p_{\omega \sigma_n} w_0 A_0 = w_0 A_0 t_{-\omega \sigma_n} \) we can see that

\[
\ell(p_{\omega \sigma_n} w_0) = \ell(w_0) + |\mathcal{P}_+| - |\mathcal{P}_-| \\
= \ell(w_0) + \ell(p_\omega) - 2|\mathcal{P}_-| \\
= \ell(w_0) + \ell(p_\omega) - 2\ell(u).
\]

Finally we obtain

\[
\ell(u^{-1}) + \ell(p_{\omega \sigma_n} w_0) = \ell(u) + \ell(w_0) + \ell(p_\omega) - 2\ell(u) = \ell(p_\omega) + (\ell(w_0) - \ell(u)) = \ell(p_\omega) + \ell(v).
\]

The claim is proved.

**Proof of the Claim 4.** Assume \( \lambda - \omega \sigma_u \notin P^- \). As we are in type \( A \) we know that for all \( \sigma \in W_0 \) and all \( \alpha \in \Phi \) we have \( |(\omega, \alpha \sigma)| \leq \pm 1 \). As \( \lambda \in P^- \), to have \( \lambda - \omega \sigma_u \notin P^- \), we must have \( (\lambda, \alpha_i) = 0 \) and \( (\omega \sigma_u, \alpha_i) = (\omega, \alpha \sigma_u^{-1}) = -1 \). In turn this implies that \( u^{-1} s_i < u^{-1} \). Thus the alcoves \( w_0 p \lambda A_0 \) and \( u^{-1} w_0 p \lambda A_0 = v \lambda A_0 \) lies on two different sides of \( H_{\alpha_i,0} \). This implies that \( (x, \alpha_i) > 0 \) for all \( x \in v \lambda A_0 \). Thus there can’t be any hyperplane of direction \( \alpha_i \) in \( H_{p \omega, v \lambda} \) as \( A_0 \) and \( v \lambda A_0 \) both lie between \( H_{\alpha_i,0} \) and \( H_{\alpha_i,1} \). The Claim follows.

### 6.2. Combinatorics of the cellular basis

In this section we study the decomposition in the Kazhdan-Lusztig basis of the element \( P(\tau) C_{w_0} \) for all \( \tau \in P^+ \). Recall that it is enough to find the expression of any element of the cellular basis in the Kazhdan-Lusztig basis, as noted in the beginning of Section 5.

We denote by \( \{\omega_1, \ldots, \omega_n\} \) the set of fundamental weights and for each \( \omega_i \in P^+ \) we denote by \( \mathcal{Q}(\omega_i) = \{\omega_i^{(1)}, \ldots, \omega_i^{(N)}\} \) its orbit under the action of \( W_0 \). Let \( x, y \in P^- \).

A path of length \( N \) from \( x \) to \( y \) is an \( (\text{ordered}) \) sequence \( x = x_0, x_1, \ldots, x_N = y \) in \( P^- \) such that for all \( 1 \leq \ell \leq N - 1 \) we have \( x_{\ell+1} = x_\ell - \omega_i^{(j)} \) and \( x_\ell \in P^- \). The element \( \omega_i^{(j)} \) is called the \( \ell \)th-step of the path from \( x \) to \( y \). A path is said to be of type \( \mathbf{m} = (m_1, \ldots, m_N) \in \{1, \ldots, n\}^N \) if its \( \ell \)th-step lies in \( \mathcal{Q}(\omega_i^{(j)}) \). Let \( \gamma \in P^- \) and \( \mathbf{m} \in \{1, \ldots, n\}^N \). We define \( \mathcal{P}(\mathbf{m}) \) to be the number of paths of type \( \mathbf{m} \) from 0 to \( \gamma \).

**Remark 6.4.** Let \( \lambda \in P^- \) be such that \( \lambda = -\sum a_i \omega_i \) for some \( a_i \geq 0 \). Let \( \mathbf{m} = (m_1, \ldots, m_N) \in \{1, \ldots, n\}^N \) be any \( N \)-tuples which contains exactly \( a_i \) i’s for all i’s. Then \( \mathcal{P}(\mathbf{m}) = 1 \) as the \( \ell \)th-step needs to be equal to \( \omega_i^{m_\ell} = \omega_i \).

**Corollary 6.5.** Let \( (a_1, \ldots, a_n) \in \mathbb{N}^n \), \( \tau = \sum a_i \omega_i \in P^+ \) and \( N = \sum a_i \). Let \( \mathbf{m} = (m_1, \ldots, m_N) \in \{1, \ldots, n\}^N \) be any \( N \)-tuples which contains exactly \( a_i \) i’s for all i’s. Then the element \( P(\tau) C_{w_0} \) of the cellular basis has the following expression in the Kazhdan-Lusztig basis :

\[
P(\tau) C_{w_0} = \sum_{\lambda \in P^-} \mathcal{P}(\mathbf{m})(\lambda) C_{w_0 p \lambda} \]

**Proof.** Let \( \lambda \in P^- \) and let \( \mathbf{m}' = (m_1, \ldots, m_{N-1}) \). Then we have

\[
\mathcal{P}(\mathbf{m})(\lambda) = \sum_{\lambda' \in P^- \setminus \lambda \in \mathcal{Q}(\omega_i)} \mathcal{P}(\mathbf{m})(\lambda').
\]

We have \( P(\tau) C_{w_0} = P(\omega_{m_N}) \ldots P(\omega_{m_1}) C_{w_0} \). Let us prove the result by induction. For \( N = 1 \) the result is true. Indeed we have \( P(\omega_1) C_{w_0} = C_{w_0, w_0} \) and there is only one path of type \( (i) \) from 0 to \( \omega_i \). Next assume that we have

\[
P(\omega_{m_N}) \ldots P(\omega_1) C_{w_0} = \sum_{\lambda \in P^-} \mathcal{P}(\mathbf{m})(\lambda) C_{w_0 p \lambda} \]

where \( \mathbf{m}' = (m_{N-1}, \ldots, 1) \).
Then
\[ P(\omega_{nN}) \cdots P(\omega_1)C_{w_0} = P(\omega_{nN}) \sum_{\lambda \in P^-} \mathcal{P}_m(\lambda)C_{w_0P\lambda} \]
\[ = \sum_{\lambda \in P^-} \mathcal{P}_m(\lambda)P(\omega_{nN})C_{w_0P\lambda} \]
\[ = \sum_{\lambda \in P^-} \mathcal{P}_m(\lambda) \left( \sum_{\gamma \in P^-} C_{w_0P\gamma} \right) \]
\[ = \sum_{\lambda \in P^-} \sum_{\gamma \in P^-} \mathcal{P}_m(\lambda)C_{w_0P\gamma} \]
\[ = \sum_{\gamma \in P^-} \sum_{\lambda \in P^-} \mathcal{P}_m(\lambda)C_{w_0P\gamma} \]
\[ = \sum_{\gamma \in P^-} \mathcal{P}_m(\gamma)C_{w_0P\gamma} \]
as required.

**Example 6.6.** In this example, we study the case of the affine Weyl group of type $\tilde{A}_2$. The quarter $\mathcal{C}^- = -\mathcal{C}^+$ is represented in figure 4. We denote by $\omega_1$ and $\omega_2$ the fundamental weights. The set of anti-dominant weights, that is $-P^+$, is just the set of points lying in $\mathcal{C}^-$ and at the intersection of 3 hyperplanes. For each antidominant weight $\lambda \in P^-$, the red (respectively green) arrows leaving from $\lambda$ represents the orbit of $\omega_1$ (respectively $\omega_2$) under the action of $W_0$.

To find the expression of the cellular basis element $P(2\omega_1 + 2\omega_2)C_{w_0}$ one needs to count the number of path of type $(1,1,2,2)$ from 0 to $\lambda$ for all $\lambda \in P^-$. This number (when non-zero) is indicated in figure 5. Hence we find

\[ P(2\omega_1 + 2\omega_2)C_{w_0} = C_{p_{21}p_{22}w_0} + C_{p_{21}w_0} + C_{p_{22}w_0} + 4C_{p_{11}p_{22}w_0} + 2C_{w_0} \]
The description of all paths form 0 to $-(\omega_1 + \omega_2)$ of type $(1,1,2,2)$ can be found in Figure 5.

**Remark 6.7.** The interpretation in term of paths also works for other types, however the situation gets more complicated as we get closer to the wall and one needs to define many different kind of paths depending on how close we are from each wall.
Figure 4. The chamber $C^{-1}$

Figure 5. Paths from 0 to $-(\omega_1 + \omega_2)$ of type $(1, 1, 2, 2)$
