Staphylococcus aureus is the most important pathogenic bacteria in humans. As the resistance of S. aureus to existing antibiotics is increasing, there is an urgent need for new anti-infective drugs. S. aureus biofilms cause persistent infections and resist complete eradication with antibiotic therapy. The present study investigated the inhibitory effect of the novel small-molecule ZY-214-4 (C₁₉H₁₁BrNO₄) on S. aureus biofilm formation. At a subinhibitory concentration (4 µg/ml), ZY-214-4 had no effect on the growth of S. aureus strains and also showed no cytotoxicity in human normal bronchial epithelial cells (Bease-2B). The results of a semi-quantitative biofilm test showed that ZY-214-4 prevented S. aureus biofilm formation, which was confirmed by scanning electron microscopy and confocal laser scanning microscopy. ZY-214-4 significantly suppressed the production of polysaccharide intercellular adhesion and prevented cell aggregation, and also inhibited the mRNA expression of icaA and other biofilm-related genes (cono, clfA/B, fnbB, fib, ebpS, psmα, and psmβ) in clinical S. aureus isolates. Thus, at a subinhibitory concentration, ZY-214-4 inhibits biofilm formation by preventing cell aggregation, highlighting its clinical potential for preventing or treating S. aureus infections.

Keywords: Staphylococcus aureus, small-molecule compound, biofilm, icaA, cell aggregation

INTRODUCTION

“An antimicrobial agent” is defined as a chemical produced by microbes that can inhibit the growth of and even destroy bacteria and other microorganisms (Waksman, 1947). Most antimicrobial agents exert bacteriostatic or bactericidal effects (Gordon et al., 2013). Staphylococcus aureus can cause a range of infections from mild skin and soft tissue to serious life-threatening infections (Bauer and Sampathkumar, 2017) that place a significant burden on healthcare systems (Dayan et al., 2016). In recent years, virulence suppression strategies have emerged to combat S. aureus that prevent infection by inhibiting the action or production of virulence factors rather than targeting bacterial pathways (Cegelski et al., 2008; Escaich, 2008). However, S. aureus is resistant to almost all known antibiotics (Lowy, 2003). As such, there is a need for new compounds that can block the production of pathogenic factors and biofilm formation by S. aureus at sub-bacterial concentrations.
Biofilm formation presents a major challenge for the eradication of chronic S. aureus infections (Craft et al., 2019). The process of biofilm formation includes initial adhesion, proliferation, maturation, and diffusion (Boles and Horswill, 2011), with polysaccharide intercellular adhesin (PIA) providing a stable hydrated matrix that holds cells together in a three-dimensional (3D) structure (Atshan et al., 2012). PIA is also known as poly-N-acetyl glucosamine and is encoded by the intercellular adhesion gene (ica) (O’Gara, 2007). The recognition of Microbial Surface Components Recognize Adhesive Matrix Molecules (MSCRAMMs) determines the primary stage of S. aureus biofilm development, that is, the initial attachment to the host cell surface. These MSCRAMMs includes elastin binding protein (ebpS), laminin-(eno), fibronectin binding protein (fnbA and fnbB), fibrinogen binding protein (fib) and aggregation factor (clfA and clfB). But separation and diffusion also play important roles. Formylated phenol-soluble modulin (PSM-mec) isolated from hospital-acquired methicillin-resistant S. aureus was shown to promote the formation of biofilm on the surface of medical instruments that resisted penetration by antibiotics, resulting in an increased rate of nosocomial infection and chronic infections (Queck et al., 2009). PSMs are major facilitators of cell spreading (Tsompanidou et al., 2013); PSM deficiency was shown to negatively affect biofilm maturation and dissociation (Periasamy et al., 2012).

ZY-214-4 (C_{19}H_{10}BrNO_{4}) is a small molecule that contains a chromone ring and N-phenyl-substituted maleimide. Chromone and its derivatives are present in natural products and pharmaceuticals as key scaffolds; and chromone derivatives have demonstrated antimicrobial activities against Penicillium, Escherichia coli, and Shigella flexneri (Verma and Pratap, 2010; Gaspar et al., 2014; Reis et al., 2017). Maleimide motifs are found in many natural products and drug candidates and exhibit a broad spectrum of biological activities including anti-tumor and antibacterial activities (Martinez et al., 2005; Wagner et al., 2009; Thoma et al., 2011). However, there has been no research to date on the antibacterial activity of chromone-maleimide hybrids.

In this study, we investigated the effect of a subinhibitory concentration of the small-molecule ZY-214-4 on S. aureus biofilm formation in order to assess the clinical potential of ZY-214-4 for preventing and treating persistent S. aureus infection.

MATERIALS AND METHODS

Bacterial Strains

The S. aureus strains used in this study are listed in Table 1. Strains SA21, SA882, and SA923 were isolated from patients at The First Affiliated Hospital of Wenzhou Medical University. The medical records of patients and S. aureus isolates were obtained for research purposes with the approval of the Ethics Committee of The First Affiliated Hospital of Wenzhou Medical University; and written, informed consent was obtained from patients.

Synthesis of ZY-214-4

ZY-214-4 was synthesized at the School of Pharmacy, Wenzhou Medical University (Figure 1). Chromone 1 (0.2 mmol, 1 equiv) and maleimide 2 (0.5 mmol, 2.5 equiv) were dissolved in a 12 ml screwcapped tube with 2 ml of 1,2-dichloroethane (0.1 M). (Ru[p-cymene]Cl)_{2} (0.01 mmol, 0.05 equiv), AgNTf_{2} (0.04 mmol, 0.2 equiv), and AgOAc (0.6 mmol, 3 equiv) were added to the reaction mixture at room temperature in air, which was then heated to 120°C in a heating mantle with stirring for 0.5 h. After terminating the reaction, the reaction mixture was loaded onto a silica gel column and purified with a petroleum ether/EtOAc mixture to obtain product 3 at a yield of 75% (Supplementary Figure 2). All reagents were used of analytical grade (Zhou et al., 2020).

Determination of Minimum Inhibitory Concentration (MIC)

ZY-214-4 was dissolved in dimethyl sulfoxide (DMSO) (Boyun, Shanghai, China) at a concentration of 20 µg/ml. The MIC of ZY-214-4 was determined with the microbroth dilution method, and was defined as the lowest concentration at which there was no visible cell growth. In order to exclude the influence of the solvent on biofilm formation, we used a DMSO control in our experiments.

Growth Assay

S. aureus strains were activated twice and added to tryptic soy broth (TSB) (BD Biosciences, Franklin Lakes, NJ, United States) at 1:200 and cultured to an optical density at 600 nm (OD_{600}) of 0.3. Appropriate amounts of ZY-214-4 were added to the culture to achieve final concentrations of 2, 4, and 8 µg/ml. An equivalent volume of DMSO was also tested to ensure that the vehicle did not affect cell growth, and cultures with TSB only served as the blank control. All cultures were incubated at 37°C with shaking at 220 rpm. And the OD_{600} values were measured every hour for a total of 24 h. The assay was performed in triplicate.

Effect of ZY-214-4 on S. aureus Biofilm Formation

ZY-214-4 was dissolved in dimethyl sulfoxide (DMSO) to a concentration of 20 mg/ml. S. aureus was inoculated in 5 ml TSB and cultured at 37°C and 220 rpm. ZY-214-4 solutions were prepared at different concentrations in TSB containing 1% glucose (Kranjec et al., 2020) and was added to bacterial cultures (1:100) in 96-well plates, with 3 parallel wells at each concentration. An equivalent volume of DMSO was also tested to ensure that the vehicle did not affect cell growth, and cultures with TSB only served as the blank control. All cultures were incubated at 37°C with shaking at 220 rpm. After incubation for 24 h, the supernatant was discarded and the wells were washed 3 times with phosphate-buffered saline (PBS). The biofilms were fixed with 99% methanol for 15 min; after discarding the supernatant, they were stained with 2% crystal violet for 10 min and rinsed under running water until the water

| Strain | MIC (µg/ml) | Source |
|--------|------------|--------|
| SA21   | 64         | Tissue |
| SA882  | 64         | Wound exudate |
| SA923  | 64         | Sputum |

was colorless. OD$_{570}$ was measured after adding 70% glacial acetic acid (Kannappan et al., 2017). TSB was used as a blank control. The assay was repeated 3 times.

**Scanning Electron Microscopy (SEM) Analysis**

A colony of *S. aureus* was picked from a blood agar plate and cultured overnight in 5 ml TSB medium at 37°C with shaking at 220 rpm (Kranjec et al., 2020). The culture was inoculated at 1:200 into 20 ml of TSB. A 3 ml volume of diluted bacterial solution was added to 6-well cell culture plates containing coverslips in each well and ZY-214-4 was added to achieve a final concentration 4 µg/ml, followed by incubation at 37°C for 24 h. Cultures without ZY-214-4 served as a control. The cells were cultured under the same conditions as for colony counting to ensure that the same number of bacteria were obtained. After removing the supernatant, the coverslip was washed 3 times with sterile PBS and freeze-dried for 2 h, then sputter-coated with gold for 3 min for SEM (Hitachi, Tokyo, Japan) observation.

**Confocal Laser Scanning Microscopy (CLSM)**

Strains were cultured in TSB in a glass-bottomed cell culture dish (NEST Biotechnology, Wuxi, China) without shaking for 24 h (Kannappan et al., 2017), in the presence of 4 µg/ml ZY-214-4; untreated samples served as a positive control. After rinsing with 0.85% saline, the dish was air-dried and 300 µl of SYTO-9 [0.02%; component A of the LIVE/DEAD BacLight Bacterial Viability kit (Thermo Fisher Scientific, Waltham, MA, United States)] and propidium iodide (0.067%) were added for 30 min in the dark at room temperature. Optical sections were scanned by CLSM (Nikon, Tokyo, Japan) using a 60 × oil-immersion objective lens. 3D reconstruction of the images was performed using NIS-Elements software (Nikon). The assay was performed in triplicate.

**Cell Aggregation Assay**

Cell aggregation was analyzed as previously described (Feldman et al., 2018). Briefly, five strains of *S. aureus* were added to 2 ml TSB at 1:200 and ZY-214-4 was added at a final concentration 4 µg/ml. The cells were cultured at 37°C and 250 rpm for 24 h; untreated samples served as the control. The cells were collected by centrifugation at 16,600×g for 2 min, washed 3 times with PBS, and resuspended in 3 ml PBS; OD$_{595}$ was adjusted to 1.5 (initial OD) in a clean glass tube, and the sample was allowed to stand at room temperature for 24 h. The supernatant was removed by aspiration and the cell pellet was resuspended in 3 ml PBS. OD$_{595}$ (final OD) was measured and the percentage of cell aggregation was determined as (final OD/initial OD) × 100%. The relative aggregation of ZY-214-4–treated samples is expressed as a percentage of the value for untreated controls (100%). The assay was performed in triplicate.

**Enzyme-Linked Dot Immunoblot Assay for PIA**

*S. aureus* was inoculated on a blood agar plate and cultured at 37°C for 14–18 h. The culture was diluted to 10$^7$ CFU/ml and added to a 6-well plate (2 ml per well) (Schlag et al., 2007). ZY-214-4 was then added to a final concentration 4 µg/ml, followed by incubation at 37°C for 24 h. Bacterial solution without ZY-214-4 served as a control. The culture medium was removed and 3 ml of EDTA was added to each well for resuspension of the biofilm attached to the bottom of the plate. The cells were transferred to a 1.5 ml centrifuge tube and incubated at 100°C for 5 min. After centrifugation at 8,000 rpm for 1 min, the supernatant was removed and 10 µl of 20 mg/ml proteinase K was added to 40 µl of supernatant, followed by incubation at 37°C for 2 h. A polyvinylidene difluoride membrane cut to an appropriate size was immersed in methanol for 3 min and deionized water for 15 min to activate functional groups on the membrane. A 10 µl volume of the extracted PIA sample was spotted onto the membrane, which was kept moist during the procedure. After the membrane had completely dried it was transferred to blocking solution [PBS with 0.1% Triton X100 (PBST) containing 3.5% bovine serum albumin] and incubated overnight at 4°C. The membrane was transferred to a Petri dish containing wheat germ agglutinin-conjugated horseradish

peroxidase and incubated at 37°C for 1 h, then washed twice with PBST for 12 min each time followed by PBS before visualizing the signal by enhanced chemiluminescence (Affinity Bio, San Francisco, United States).

**Real-Time (RT)-PCR**

*S. aureus* strains were cultured in TSB containing ZY-214-4 at an inhibitory concentration (4 µg/ml). After 12 h, total RNA was extracted from the cells and cDNA was synthesized using an RNA PCR kit (Takara Bio, Otsu, Japan). PCR was performed in a 20 µl reaction volume using Luna Universal qPCR Master Mix (New England Biolabs, Ipswich, MA, United States). The primer pairs used for RT-PCR are shown in Table 2. The assay was performed in triplicate.

**Cytotoxicity Analysis**

The cytotoxicity of ZY-214-4 was evaluated with the Cell Counting Kit (CCK)-8 assay using Bease-2B human normal bronchial epithelial cells. The cells were seeded in a 96-well plate containing Dulbecco’s Modified Eagle’s Medium (DMEM)/F12 at 4,000 cells/well, and 10% fetal bovine serum (FBS) was added to each well, followed by incubation at 37°C and 5% CO₂ in a humid environment for 12 h. The supernatant was discarded and the wells were washed 3 times with PBS. DMEM/12 was added to each well, followed by incubation at 37°C for 1.5 h at 37°C and measurement of OD₄₅₀. Relative cell viability (%) was determined by comparing the OD₄₅₀ value with that of the control well containing only cell culture medium.

**RESULTS**

**ZY-214-4 Suppresses *S. aureus* Growth**

The MIC of ZY-214-4 for *S. aureus* strains SA21, SA882, and SA923 was 64 µg/ml. We generated growth curves for cells treated with various concentrations of ZY-214-4 and found that at the subinhibitory concentration of 4 µg/ml, the number of cells in the late logarithmic growth phase was consistent across strains (Figure 2). Therefore, 4 µg/ml ZY-214-4 was used for subsequent experiments.

**ZY-214-4 Prevents *S. aureus* Biofilm Formation**

*S. aureus* forms biofilm, which protects it against the action of anti-bacterial drugs. We used a semi-quantitative method to evaluate the effect of ZY-214-4 on *S. aureus* biofilm formation. *S. aureus* treated with ZY214-4 (4 µg/ml) had a 7.5–13 times lower OD₅₇₀ than untreated cells (0.2–0.4 vs. 2.6–3.0), with biofilm formation reduced by 83.3–91.5% (Figure 3). SEM analysis of *S. aureus* biofilms showed a high degree of aggregation of SA21 and SA923 in the absence of treatment. However, in ZY-214-4–treated samples, cell aggregates covered a smaller area and were scattered, with greater distance between colonies (Figures 4A,B). Examination of 3D biofilm morphology by CLSM showed that compared to the control sample, the thickness of the biofilm was decreased and the area covered by the biofilm was reduced by ZY-214-4 treatment (Figures 4C,D).

**ZY-214-4 Prevents *S. aureus* Aggregation**

Cell aggregation plays an important role in biofilm formation. Autoaggregation was observed after incubating *S. aureus* strains for 24 h under static conditions (Figure 5A). The cell aggregation rate was significantly decreased by treatment with ZY-214-4 to 68.1–83.1% of the value in untreated control samples (Figure 5B).

**ZY-214-4 Inhibits PIA Production by *S. aureus***

Extracellular PIA is the main component of staphylococcal biofilms. To investigate the effect of ZY-214-4 on the production of biofilm matrix, we measured PIA release in cultures. As shown in Figure 6, when the PIA antigen was diluted to 5,000-fold, as determined by the semi-quantitative determination of the WGA-HRP conjugate using the dot blot 96 system, among the strains treated with

ZY-214-4 and untreated strains. This indicates that ZY-214-4 prevented S. aureus biofilm formation by inhibiting the production of PIA.

**ZY-214-4 Suppresses the Expression of S. aureus Biofilm-Related Genes**

PIA synthesis depends on the expression of the icaA gene, but genes encoding microbial surface components that recognize MSCRAMM also play a key role in biofilm formation. PSMs influence bacterial cell aggregation, and their absence can affect biofilm maturation and dissociation. To clarify the mechanism by which ZY-214-4 blocks S. aureus biofilm formation, we compared the expression of biofilm-related genes between untreated and ZY-214-4-treated S. aureus by RT-PCR. The results showed that the expression of icaA, eno, clfA/B, fnbB, fib, ebpS, psmα, and psmβ genes was downregulated to varying degrees in the latter cells (Figure 7).

**ZY-214-4 Is Nontoxic to Bease-2b Cells**

We evaluated the cytotoxicity of ZY-214-4 with the CCK-8 assay using Bease-2B human normal bronchial epithelial cells. There was no difference in viability between control and ZY-214-4 treated groups (Figure 8A) and microscopic observation revealed no differences in cell morphology (Figure 8B), indicating that ZY-214-4 is not cytotoxic at a subinhibitory concentration.

**DISCUSSION**

Biofilms are fixed communities of bacterial cells attached to each other and embedded in a self-produced extracellular polymer (EPS) matrix (Flemming and Wingender, 2010). Biofilms can be formed on various surfaces including ducts, implants, prosthetics, and implanted medical devices (Costerton et al., 1999). There is evidence that cells in biofilms on biotic or abiotic surfaces are 1,000 times more resistant to conventional drugs than planktonic cells (Parsek and Singh, 2003; Verderosa et al., 2019). Once formed, a biofilm is difficult to eliminate and can develop into a chronic and persistent infection.

In this study, we synthesized the small-molecule compound ZY-214-4 and evaluated its antibacterial efficacy against clinical isolates of S. aureus obtained from different infection sites. A high concentration of ZY-214-4 inhibited the growth of S. aureus (Supplementary Figure S1) while no effect was observed at the subinhibitory concentration of 4 µg/ml. We therefore used the latter in our experiments in order to exclude the possibility that ZY-214-4 prevents S. aureus biofilm formation by suppressing cell proliferation.

Downregulation of the ica gene encoding PIA is a known mechanism of S. aureus biofilm inhibition (Cramton et al., 1999). We found that PIA production by S. aureus was
Yu et al. Small-Molecule ZY-214-4 Inhibit the Biofilm Formation of Staphylococcus aureus

**FIGURE 7** | Effect of ZY-214-4 on relative expression of biofilm-related genes in S. aureus. Values represent mean ± SD. Cells grown without ZY-214-4 served as a control. *P < 0.05.

**FIGURE 8** | Effect of ZY-214-4 on the growth and morphology of Bease-2B human normal bronchial epithelial cells. (A) CCK-8 assay. (B) Cell morphology and number evaluated by light microscopy.

decreased by treatment with 4 µg/ml ZY-214-4. This is consistent with the relevant research results of Lee et al. (2013, 2014) on compounds inhibiting the formation of bacterial biofilms. Bacterial cell aggregation is an initial step in biofilm formation (Arciola et al., 2012). In staphylococci, PIA promotes cell–cell adhesion, which is important for cell aggregation following attachment to a surface (Mack et al., 1994; Heilmann et al., 1996). PSMs—especially PSM β—play an important role in cell aggregation (Periasamy et al., 2012; Kim et al., 2020). In this study we found that downregulation of the psm gene in the presence of ZY-214-4 was associated with a reduction in S. aureus cell aggregation. A consistent conclusion can be found in the relevant research of Lee et al. (2016). Additionally, the expression of genes involved in the initial attachment of cells to each other (ento, clfA/B, fnbB, fib, and ebpS) was also decreased. Thus, ZY-214-4 prevents biofilm formation by S. aureus by blocking the production of PIA and cell aggregation.

Importantly, ZY-214-4 had no cytotoxicity in Bease-2B epithelial cells at a subinhibitory concentration, suggesting that it is safe for use in humans.

This study had some limitations. For example, the mechanism by which ZY-214-4 regulates the expression of icaA, psm, and other biofilm-related genes remains to be determined. Nonetheless, we demonstrated that the small-molecule ZY-214-4 is non-toxic to human cells and effective in preventing biofilm formation by S. aureus at a subinhibitory concentration. These findings highlight the clinical potential of ZY-214-4 for the prevention and treatment of chronic S. aureus infections.
