Particle Motion in the Stable Region Near the Edge of a Linear Sum Resonance Stopband

George Parzen
October 23, 1995
BNL-62546

ABSTRACT

This paper studies the particle motion when the tune is in the stable region close to the edge of linear sum resonance stopband. Results are found for the tune and the beta functions. Results are also found for the two solutions of the equations of motion. The results found are shown to be also valid for small accelerators where the large accelerator approximation may not be used.

1. Introduction

This paper studies the motion of a particle whose tune is near an edge of a linear sum resonance stopband. It is assumed that the tune is not near any other linear resonance, and the motion is dominated by the linear sum resonance. It is assumed that the linear sum resonance is being driven by a skew quadrupole field perturbation. When the unperturbed tune $\nu_{x0}, \nu_{y0}$ is close to the resonance line $\nu_x + \nu_y = q$, $q$ being an integer, the particle motion can be unstable. The region of instability is called the stopband. Results are found for the tune and the beta functions when the unperturbed tune is in the stable region but close to an edge of the stopband. Results are also found for the two solutions of the equations of motion. All the results found are shown to be also valid for small accelerators where the large accelerator approximation may not be used.
2. Results When The Tune Is Inside The Stopband

It will be assumed that in the absence of the perturbing fields, the tune of the particle is given by $\nu_{x0}, \nu_{y0}$, the $x$ and $y$ motions are uncoupled, and that the motion is stable when $\nu_{x0}, \nu_{y0}$ is close to the line $\nu_{x0} + \nu_{y0} = q$, where $q$ is an integer. It is assumed that a perturbing field is then added which is given by the skew quadrupole field

$$\Delta B_x = -B_0 a_1 x$$
$$\Delta B_y = B_0 a_1 y$$

$a_1$ is the skew quadrupole multipole and $a_1 = a_1(s)$. $B_0$ is some standard field, usually the field in the main dipoles of the lattice.

The coupled equations of motion can be written as

$$\frac{d^2 \eta_x}{d\theta_x^2} + \nu_{x0}^2 \eta_x = f_x$$
$$\frac{d^2 \eta_y}{d\theta_y^2} + \nu_{y0}^2 \eta_y = f_y$$

$$f_x = \nu_{x0}^2 \beta_x^{3/2} \Delta B_y / B \rho$$
$$f_y = -\nu_{y0}^2 \beta_y^{3/2} \Delta B_x / B \rho$$

$$\eta_x = x / \beta_x^{1/2}, \quad \eta_y = y / \beta_y^{1/2}$$

$$\rho = B \rho / B_0, \quad B \rho = p c / e$$

$$ds = \nu_{x0} \beta_x d\theta_x = \nu_{y0} \beta_y d\theta_y$$

$\beta_x, \beta_y$ are the unperturbed beta functions.

Eqs. (2-2) are valid for large accelerators, and some changes are required [1] to make them valid for small accelerators (see section 6). However the final results found below are also valid for small accelerators that require the use of the exact linearized equations. This is shown in section 6.

Eq. (2-2) can be rewritten as

$$\frac{d^2 \eta_x}{d\theta_x^2} + \nu_{x0}^2 \eta_x = b_x \eta_y$$
$$\frac{d^2 \eta_y}{d\theta_y^2} + \nu_{y0}^2 \eta_y = b_y \eta_x$$

$$b_x = -\nu_{x0}^2 \beta_x (\beta_x \beta_y)^{1/2} a_1 / \rho$$
$$b_y = -\nu_{y0}^2 \beta_y (\beta_x \beta_y)^{1/2} a_1 / \rho$$

(2-3)
Eqs. (2-3) are a set of linear equations for $\eta_x, \eta_y$ with coefficients that are periodic in $s$. The extension of Floquet’s theorem to more than one dimension applies, and the solutions have the Floquet form,

$$\begin{bmatrix} \eta_x \\ \eta_y \end{bmatrix} = \exp (i\nu_x \theta_x) \begin{bmatrix} h_x \\ h_y \end{bmatrix}$$

(2-4)

$h_x$ and $h_y$ are periodic in $s$. The solution can also have the form

$$\begin{bmatrix} \eta_x \\ \eta_y \end{bmatrix} = \exp (i\nu_y \theta_y) \begin{bmatrix} h_x \\ h_y \end{bmatrix}$$

(2-5)

If for small $a_1$ one finds a solution of the form Eq. (2-4) where $h_y \to 0$ when $a_1 \to 0$, then $\nu_x \to \nu_{x0}$. This solution reduces to the uncoupled $x$ motion when $a_1 \to 0$ and will be called the $\nu_x$ mode. If for small $a_1$, one finds a solution of the form Eq. (2-5) where $h_x \to 0$, when $a_1 \to 0$, then $\nu_y \to \nu_{y0}$ and thus this solution will be called the $\nu_y$ mode.

To find the solution that corresponds to the $\nu_x$ mode, one can assume that $\eta_x$ has the form

$$\eta_x = A_s \exp (i\nu_{xs} \theta_x) + \sum_{r \neq s} A_r \exp (i\nu_{xr} \theta_x)$$

(2-6a)

$$\nu_{xr} = \nu_{xs} + n, \quad n \text{ an integer, } n \neq 0$$

where for small enough $a_1$, $A_r \ll A_s$ and $\nu_{xs} \to \nu_{x0}$ for $a_1 \to 0$. For the corresponding form for $\eta_y$ one might assume for $\eta_y$

$$\eta_y = \sum_{r} B_r \exp (i\nu_{yr} \theta_y)$$

(2-6b)

$$\nu_{yr} = \nu_{xs} + n$$

where $B_r \ll A_s$ for small enough $a_1$.

Eqs. (2-6) have the form given by Eq. (2-4) for the $\nu_x$ mode. It will be seen below, that the solution assumed for $\eta_y$ Eq. (2-6b) is valid if one is not near the sum resonance $\nu_x + \nu_y = q$, $q$ being an integer. When $\nu_{x0}, \nu_{y0}$ are close to the sum resonance $\nu_x + \nu_y = q$, then one of the $B_r$ will become as large as $A_s$ and this is the $B_r$ for which $\nu_{yr} = \nu_{xs} - q$. This is shown below. Thus, one assumes for $\eta_y$ the solution with the form

$$\eta_y = B_s \exp (i\nu_{ys} \theta_y) + \sum_{r \neq s} B_r \exp (i\nu_{yr} \theta_y)$$

(2-6c)

$$\nu_{ys} = \nu_{xs} - q$$

$$\nu_{yr} = \nu_{xs} + n, \quad n \neq -q$$
Here \( B_r \ll A_s \) but \( B_\pi \simeq A_s \). It is being assumed that \( \nu_{x0}, \nu_{y0} \) are not close to any other resonance other than \( \nu_x + \nu_y = q \).

Putting this assumed form for \( \eta_x, \eta_y \) into the differential equations Eq. (2-3), one gets the equations for \( A_r, B_r \)

\[
\begin{align*}
(\nu_{x0}^2 - \nu_{x0}^2) A_r &= -2\nu_{x0} \sum_{r'} b_x (-\nu_{x0}, \nu_{y0}) B_{r'} \\
(\nu_{y0}^2 - \nu_{y0}^2) B_r &= -2\nu_{y0} \sum_{r'} b_y (-\nu_{y0}, \nu_{x0}) A_{r'} \tag{2-7}
\end{align*}
\]

\[
\begin{align*}
b_x (-\nu_{x0}, \nu_{y0}) &= \frac{1}{4\pi} \int_0^L ds (\beta_x \beta_y)^{1/2} (a_1/\rho) \exp \left[ i (\nu_{x0} \theta_x + \nu_{y0} \theta_y) \right] \\
b_y (-\nu_{y0}, \nu_{x0}) &= \frac{1}{4\pi} \int_0^L ds (\beta_x \beta_y)^{1/2} (a_1/\rho) \exp \left[ i (\nu_{y0} \theta_y + \nu_{x0} \theta_x) \right]
\end{align*}
\]

\( L \) is the lattice circumference.

Eqs. (2-7) can be solved by an iterative perturbation procedure. For the initial guess for \( \eta_x, \eta_y \) in the iterative procedure one can assume

\[
\begin{align*}
\eta_x &= A_s \exp (i\nu_x \theta_x) \\
\eta_y &= B_\pi \exp (i\nu_y \theta_y) \tag{2-8}
\end{align*}
\]

\[
\nu_\pi = \nu_{xs} - q = -(q - \nu_{xs})
\]

One can put this initial guess for \( \eta_x, \eta_y \) in the right hand side of Eq. (2-7) and solve for the \( A_r, B_r \) which gives

\[
\begin{align*}
(\nu_{x0}^2 - \nu_{x0}^2) A_r &= -2\nu_{x0} \sum_{r'} b_x (-\nu_{x0}, \nu_{y0}) B_{r'} \\
(\nu_{y0}^2 - \nu_{y0}^2) B_r &= -2\nu_{y0} \sum_{r'} b_y (-\nu_{y0}, \nu_{x0}) A_{r'} \tag{2-9}
\end{align*}
\]

\[
\begin{align*}
\nu_{x0} &= \nu_{xs} + n, \quad \nu_{y0} = \nu_{xs} + m
\end{align*}
\]

For \( A_r = A_s \) and \( B_r = B_\pi \) one finds

\[
\begin{align*}
(\nu_{x0}^2 - \nu_{x0}^2) A_s &= -2\nu_{x0} \sum_{r'} b_x (-\nu_{xs}, \nu_{y0}) B_{\pi} \\
(\nu_{y0}^2 - \nu_{y0}^2) B_\pi &= -2\nu_{y0} \sum_{r'} b_y (-\nu_{y0}, \nu_{xs}) A_s \tag{2-10}
\end{align*}
\]

\[
\begin{align*}
\nu_{y0} &= -(q - \nu_{xs})
\end{align*}
\]

Eqs. (2-10) are two linear homogeneous equations for \( A_s \) and \( B_\pi \), and to be solvable, we must have

\[
\begin{align*}
(\nu_{x0}^2 - \nu_{x0}^2)(\nu_{y0}^2 - \nu_{y0}^2) &= 4\nu_{x0}\nu_{y0} |\Delta \nu_x|^2 \\
\Delta \nu_x &= \frac{1}{4\pi} \int_0^L ds (\beta_x \beta_y)^{1/2} (a_1/\rho) \exp \left[ -i (\nu_{x0} \theta_x + (q - \nu_{x0}) \theta_y) \right] \tag{2-11}
\end{align*}
\]
where one uses $b_y(-\nu_{y0}, \nu_{xs}) = b_x^*(-\nu_{xs}, \nu_{y0})$. Eq. (2-11) is an equation for $\nu_{xs}$, the tune of the $\nu_x$ mode, which is the mode where $\nu_{xs} \to \nu_{x0}$ when $a_1 \to 0$. It will be assumed that $\nu_{x0}$, $\nu_{y0}$ is close to the resonance line $\nu_x + \nu_y = q$ and one can write

\[
\begin{align*}
(\nu_{xs}^2 - \nu_{x0}^2) &= (\nu_{xs} + \nu_{x0})(\nu_{xs} - \nu_{x0}) \approx 2\nu_{x0}(\nu_{xs} - \nu_{x0}) \\
(\nu_{ys}^2 - \nu_{y0}^2) &= (\nu_{ys} + \nu_{y0})(|\nu_{ys}| - \nu_{y0}) \approx 2\nu_{y0}(q - \nu_{xs} - \nu_{y0})
\end{align*}
\]

Eq. (2-11) then becomes

\[
(\nu_{xs} - \nu_{x0})(q - \nu_{xs} - \nu_{y0}) = |\Delta \nu_x|
\]

To solve Eq. (2-13) one puts

\[
\nu_{xs} = \nu_{xsR} - ig_x
\]

where $\nu_{xsR}$ and $g_x$ are both real, which gives the equation

\[
(\nu_{xsR} - ig_x - \nu_{x0})(q - \nu_{xsR} + ig_x - \nu_{y0}) = |\Delta \nu_x|^2
\]

The imaginary part of Eq. (2-14) gives

\[
g_x [\nu_{xsR} - \nu_{x0}(q - \nu_{xsR} - \nu_{y0})] = 0
\]

If one is inside the stopband, then $g_x \neq 0$ and one gets

\[
\nu_{xsR} = \frac{1}{2}[\nu_{x0} + q - \nu_{y0}]
\]

The real part of Eq. (2-14) gives

\[
(\nu_{xsR} - \nu_{x0}) (q - \nu_{xsR} - \nu_{y0}) + q_x^2 = |\Delta \nu_x|^2
\]

Using Eq. (2-16) for $\nu_{xsR}$ one has

\[
\begin{align*}
\nu_{xsR} - \nu_{x0} &= \frac{1}{2}[-\nu_{x0} + (q - \nu_{y0})] \\
q - \nu_{xsR} - \nu_{y0} &= \frac{1}{2}[(q - \nu_{y0}) - \nu_{x0}]
\end{align*}
\]

Eq. (2-17) then gives

\[
g_x^2 + \left[\frac{1}{2}(q - \nu_{x0} - \nu_{y0})\right]^2 = |\Delta \nu_x|^2
\]

\[
g_x = \pm \left\{|\Delta \nu_x|^2 - \left[\frac{1}{2}(q - \nu_{x0} - \nu_{y0})\right]^2\right\}^{1/2}
\]
Eq. (2-19) shows that the growth factor $g_x$ has a maximum value of $g_x = |\Delta \nu_x|$ when $\nu_{x0}$, $\nu_{y0}$ are on the resonance line, $q - \nu_{x0} - \nu_{y0} = 0$, and then decreases to zero at the edges of the stopband given by the two lines

$$q - \nu_{x0} - \nu_{y0} = \pm 2|\Delta \nu_x|$$  \hspace{1cm} (2-20)

Eq. (2-19) shows that the unstable region in $\nu_{x0}$, $\nu_{y0}$ is bounded by the two lines given by Eq. (2-20). These two lines are parallel to the resonance line $q - \nu_{x0} - \nu_{y0} = 0$, which lies midway between these two lines. If one wanted to define a stopband width, one might define it as the distance in $\nu_{x0}$, $\nu_{y0}$ space across the unstable region, along a path which is perpendicular to the two boundary lines. This is given by

$$\text{stopband width} = 2.828|\Delta \nu_x|$$  \hspace{1cm} (2-21)

For particle motion in 2 dimensional phase space, it has been found [2] that the real part of the tune is constant as the unperturbed tune moves across the stopband. This is not in general true for 4 dimensional phase, as the real part of the tune, given by Eq. (2-16), depends on the path in $\nu_{x0}$, $\nu_{y0}$ which is chosen in crossing the stopband. However, if one chooses a path which is perpendicular to the resonance line, $q - \nu_{x0} - \nu_{y0} = 0$, then the real part of the tune does remain constant. One can see this by observing that if starting from $\nu_{x0}$, $\nu_{y0}$ one draws a line perpendicular to the resonance line, the point on the resonance line that this perpendicular meets has the coordinates

$$\frac{1}{2}(\nu_{x0} + q - \nu_{y0}), \quad \frac{1}{2}(\nu_{y0} + q - \nu_{x0})$$  \hspace{1cm} (2-22)

The $\nu_x$ coordinate of this point is just $\nu_{xSR}$ as given by Eq. (2-16).

The above results are for the $\nu_x$ mode, the mode for which the tune approaches $\nu_{x0}$ when $a_1 \to 0$. One can find the corresponding results for the $\nu_y$ mode by using the following substitutions

$$\nu_{x0} \to \nu_{y0}$$
$$\nu_{y0} \to \nu_{x0}$$
$$\Delta \nu_x \to \Delta \nu_y$$
$$g_x \to g_y$$  \hspace{1cm} (2-23)
The apparent differences between \( g_x \) and \( g_y \) and \( \Delta \nu_x \) and \( \Delta \nu_y \) are negligible if \( \nu_{x0}, \nu_{y0} \) are close to the resonance line. \( \Delta \nu_x, \Delta \nu_y \) can be written as

\[
\Delta \nu = \frac{1}{4\pi} \int ds \left( \beta_x \beta_y \right)^{\frac{1}{2}} (a_1/\rho) \exp \left[ -i \left( \nu_x \theta_x + \nu_y \theta_y \right) \right]
\]

(2-24a)

where for the \( \nu_x \) mode, \( \nu_x, \nu_y \) is the point on the resonance line

\[
\nu_x = \nu_{x0}, \nu_y = q - \nu_{x0}
\]

(2-24b)

and for the \( \nu_y \) mode, \( \nu_x, \nu_y \) is the point on the resonance line.

\[
\nu_x = q - \nu_{y0}, \nu_y = \nu_{y0}
\]

(2-24c)

These two points on the resonance line are close if \( \nu_{x0}, \nu_{y0} \) is assumed to be close to the resonance line, and their difference can be neglected. A reasonable compromise might be to choose for \( \nu_x, \nu_y \) the point on the resonance line which is midway between these two points, which is the choice of \( \nu_x, \nu_y \) given by

\[
\nu_x = \frac{1}{2} (\nu_{x0} + q - \nu_{y0}), \nu_y = \frac{1}{2} (\nu_{y0} + q - \nu_{x0})
\]

(2-25)

3. Solutions of the Equations of Motion

Now let us find the solutions for \( \eta_x, \eta_y \) that will give the particle motion inside the stopband. To lowest order \( \eta_x \) and \( \eta_y \) are given by Eqs. (2-6) for the \( \nu_x \) mode as

\[
\eta_x = A_s \exp \left( i\nu_{x0} \theta_x \right)
\]

\[
\eta_y = B_s \exp \left( i\nu_{y0} \theta_y \right)
\]

(3-1)

From Eq. (2-10) one finds that inside the stopband

\[
B_s = -\frac{\Delta \nu_x^*}{|\nu_{y0} - \nu_{y0}|} A_s
\]

(3-2)

Since

\[
|\nu_{y0}| - \nu_{y0} = q - \nu_{x} - \nu_{y0}
\]

\[
= q - \nu_{x} + \nu_{x0} + i g_x - \nu_{y0}
\]

\[
= q - \nu_{y0} - \frac{1}{2} \left[ \nu_{x0} + q - \nu_{y0} \right] + i g_x
\]

\[
= \frac{1}{2} \left[ q - \nu_{x0} - \nu_{y0} \right] + i g_x
\]

(3-3)
one gets

\[ B_\pi = - \exp[-i(\delta_{1x} + \delta_{2x})] A_s \]

\[ \delta_{1x} = ph(\Delta \nu_x) \]

\[ \delta_{2x} = ph\left[ \frac{1}{2}(q - \nu_{x0} - \nu_{y0}) + ig_x \right] \]

where use was made of Eq. (2-19) and \( ph \) indicates the phase of a variable.

Thus, inside the stopband, \( \eta_x \) and \( \eta_y \) are of the same order of magnitude one can find the first order correction to \( \eta_x \) and \( \eta_y \) using Eq. (2-9). The results for \( \eta_x \) and \( \eta_y \) for the \( \nu_y \) mode can be found by using the substitutions given by Eqs. (2-23).

Results will now be found for \( \eta_x \) and \( \eta_y \) which are correct to first order in the perturbation and when \( \nu_{x0}, \nu_{y0} \) is inside the stopband or in the stable region near an edge of the stopband. \( \eta_x, \eta_y \) are given by Eqs. (2-6). For the \( \nu_x \) mode

\[ \eta_x = A_s \exp(i\nu_{xs}\theta_x) + \sum_{r \neq s} A_r \exp(i\nu_{xr}\theta_x) \]

\[ \eta_y = B_\pi \exp(i\nu_{ys}\theta_y) + \sum_{r \neq s} B_r \exp(i\nu_{yr}\theta_y) \]  

\[ \nu_{ys} = \nu_{xs} - q \]

\[ \nu_{yr} = \nu_{xs} + n, \quad n \neq -q \]

\[ \nu_{xr} = \nu_{xs} + n, \quad n \neq 0 \]

The first order solution is given by Eqs. (2-9) and (2-10). \( B_\pi, A_r \) and \( B_r \) are given by Eq. (2-7)

\[ B_\pi = -2\nu_{y0}b_y (-\nu_{ys}, \nu_{xs}) A_s / (\nu_{ys}^2 - \nu_{y0}^2) \]

\[ A_r = -2\nu_{x0}b_x (-\nu_{xr}, \nu_{ys}) B_\pi / (\nu_{xr}^2 - \nu_{x0}^2) \]

\[ B_r = -2\nu_{y0}b_y (-\nu_{yr}, \nu_{xs}) A_s / (\nu_{yr}^2 - \nu_{y0}^2) \]

\[ \nu_{xr} = \nu_{xs} - m \quad m \neq 0 \]

\[ \nu_{yr} = \nu_{ys} + n \quad n \neq 0 \]

First, let us compute \( B_\pi \).

\[ \nu_{ys}^2 - \nu_{y0}^2 = (|\nu_{ys}| + \nu_{y0}) (|\nu_{ys}| - \nu_{y0}) = 2\nu_{y0}(q - \nu_{xs} - \nu_{y0}) \]  

\[ \nu_{xs} = \frac{1}{2}(\nu_{x0} + q - \nu_{y0}) - \delta_x \]
where $\delta_x = ig_x$, see Eq. (2-19) for $g_x$, when the tune is inside the stopband. In the stable region near an edge of a stopband, $\nu_{xs}$ and $\delta_x$ are given in section 4. Note that $\delta_x = 0$ when the tune is on the edge of the stopband. Then Eq. (3-7) gives

$$\nu_{ys}^2 - \nu_{y0}^2 = 2\nu_{y0} \left(\frac{1}{2} (q - \nu_{x0} - \nu_{y0}) + \delta_x\right) \quad (3-9)$$

One also finds

$$b_x (-\nu_{ys}, \nu_{xs}) = \Delta \nu_x^*$$
$$B_\pi = -d_x \exp (-i\delta_{1x}) A_s$$
$$d_x = -\frac{1}{2} (q - \nu_{x0} - \nu_{y0}) \exp (-i\delta_{1x}) A_s \quad (3-10)$$
$$\delta_{1x} = \text{ph} (\Delta \nu_x)$$

One may note that inside the stopband

$$d_x = -\exp [-i (\delta_{1x} + \delta_{2x})] A_s$$
$$\delta_{2x} = \text{ph} \left[\frac{1}{2} (q - \nu_{x0} - \nu_{y0}) + ig_x\right] \quad (3-11)$$

One may now find the $A_r$ from Eq. (3-6)

$$\nu_{xr} = \nu_{xs} - m, \quad m \neq 0$$
$$\nu_{xr}^2 - \nu_{x0}^2 = m (m - 2\nu_{x0})$$

$$b_x (-\nu_{xr}, \nu_{ys}) = b_m$$
$$b_m = \frac{1}{4\pi} \int ds \left(\frac{a_1}{\rho}\right) (\beta_x \beta_y)^{\frac{1}{2}} \exp [-i ((q - \nu_{x0}) \theta_y + \nu_{x0} \theta_x) + im \theta_x] \quad (3-12)$$

$$A_r = \frac{-2\nu_{x0}}{m (m - 2\nu_{x0})} b_m B_\pi$$

$$A_r = \frac{-2\nu_{x0}}{m (m - 2\nu_{x0})} d_x b_m \exp (-i\delta_{1x}) A_s$$

One may find the $B_r$ from Eq. (3-6)

$$\nu_{yr} = \nu_{ys} + n, \quad n = 0$$

$$\nu_{ys} = \nu_{xs} - q$$

$$\nu_{yr}^2 - \nu_{y0}^2 = n (n - 2 (q - \nu_{x0}))$$

$$b_y (-\nu_{yr}, \nu_{xs}) = c_n^*$$

$$c_n = \frac{1}{4\pi} \int ds \left(\frac{a_1}{\rho}\right) (\beta_x \beta_y)^{\frac{1}{2}} \exp [-i ((q - \nu_{x0}) \theta_y + \nu_{x0} \theta_x) + in \theta_y]$$

$$B_r = \frac{-2\nu_{y0}}{n (n - 2 (q - \nu_{x0}))} c_n^* A_s \quad (3-13)$$
Putting these results for $B_s$, $A_r$, $B_r$ into Eq. (3-5), one finds the following results for $\eta_x$, $\eta_y$ for the $\nu_x$ mode.

$$\eta_x = A_s \exp \left( i\nu_x \theta_x \right) \left[ 1 + \sum_{m \neq 0} f_m \exp \left( -i m \theta_x \right) \right]$$

$$f_m = \frac{-2\nu_x}{m (m - 2\nu_x)} d_x b_m \exp \left( -i \delta_{1x} \right)$$

$$d_x = \frac{-|\Delta \nu_x|}{\frac{1}{2} (q - \nu_y - \nu_x) + \delta_x}$$

$$\eta_y = A_s \exp \left( i\nu_y \theta_y \right) \left[ 1 + \sum_{n \neq 0} g_n \exp \left( in \theta_y \right) \right]$$

$$g_n = \frac{-2\nu_y}{n (n - 2 (q - \nu_x))} C_n^*$$

$$\nu_y = \nu_{xs} - q$$

$\delta_x$ is given by $i \ g_x$ inside the stopband where $g_x$ is given by Eq. (2-19) as

$$g_x = \left\{ |\Delta \nu_x|^2 - \left[ \frac{1}{2} (q - \nu_x - \nu_y) \right]^2 \right\}^{1/2}$$

(3-15a)

In the stable region near a stopband edge, $\delta_x$ is given by Eq. (4-10) as

$$|\delta_x| = \left\{ \epsilon_x \left( |\Delta \nu_x| + \epsilon_x/4 \right) \right\}^{1/2}$$

$$\epsilon_x = |q \pm |2\Delta \nu_x| - \nu_x - \nu_y|$$

(3-15b)

One uses the + sign for the upper stopband edge and the − sign for the lower edge. $\delta_x$ is positive for the lower edge and negative for the upper edge.

Equations (3-4) give the solutions of the equations of motion for the $\nu_x$ mode. The solutions for the $\nu_y$ mode are found by replacing each parameter for the $\nu_x$ mode by its corresponding parameter for the $\nu_y$ mode.

One may note from Eq. (3-14) that for the $\nu_x$ mode the dominant harmonic for $\eta_x$ is $m \simeq 2\nu_x$, and for $\eta_y$ $n = 2|\nu_y| = 2(q - \nu_x)$. Keeping just the dominant harmonics give fairly simple results for $\eta_x$, $\eta_y$. 
4. The Tune Near the Edge of a Stopband

In this section, a result will be found for the tune in the stable region outside the stopband but close to an edge of the stopband. It will be shown that close to an edge of the stopband the tune of the $\nu_x$ mode is given by

$$|\nu_x - \frac{1}{2}(\nu_x + q - \nu_y)| = \{\epsilon_x|\Delta \nu_x|\}^{\frac{1}{2}}$$

$$\epsilon_x = |q \pm 2|\Delta \nu_x| - \nu_x - \nu_y|$$

(4-1)

$\nu_x$ is the tune of the $\nu_x$ mode, $\epsilon$ is the distance from $\nu_x$, $\nu_y$ to the edge of the stopband. In the $\pm$, the + sign is for the upper edge, and the − sign for the lower edge. When $\nu_x$, $\nu_y$ reaches the edge of the stopband, then $\epsilon = 0$, and $\nu_x = \frac{1}{2}(\nu_x + q - \nu_y)$, which according to Eq. (2-16) is the real part of the tune inside the stopband.

Eq. (4-1) shows that near the stopband edge, $\nu_x$ varies rapidly with $\epsilon_x$. As one reaches the edge of the stopband, $\epsilon_x$ goes to zero and $d\nu_x/d\epsilon_x$ becomes infinite like $\epsilon_x^{-\frac{1}{2}}$.

To find $\nu_x$ in the stable region outside the stopband, where $|q - \nu_x - \nu_y| > 2|\Delta \nu_x|$, one goes back to the derivation given in section 2 for $\nu_x$ inside the stopband, starting with Eq. (2-13)

$$(\nu_x - \nu_x)(q - \nu_x - \nu_y) = |\Delta \nu_x|^2$$

(4-2)

Because of the condition that $\nu_x$ is outside the stopband or

$$|q - \nu_x - \nu_y| > 2|\Delta \nu_x|$$

(4-3)

one sees that one must have $g_x = 0$, as Eq. (2-19) would indicate $g_x$ is imaginary which contradicts the assumption that $g_x$ is real.

Let us assume that we start with $\nu_x$, $\nu_y$ below the lower stopband edge and let $\nu_x$, $\nu_y$ approach the lower stopband edge. The equation of the lower stopband edge is given by

$$q - \nu_x - \nu_y = 2|\Delta \nu_x|$$

(4-4)

when $\nu_x$, $\nu_y$ arrive on the lower stopband edge, then $\nu_x$ will arrive at the value $\nu_x = \frac{1}{2}(\nu_x + q - \nu_y)$ as indicated by Eq. (2-16). Thus below the stopband edge one can write

$$\nu_x = \frac{1}{2}(\nu_x + q - \nu_y) - \delta_x$$

(4-5)
where $\delta_x \to 0$ when $\nu_x, \nu_y$ arrive at the stopband edge. We then find
\[
\nu_x - \nu_{x0} = \frac{1}{2} (q - \nu_{x0} - \nu_{y0}) - \delta_x
\]
and $\nu_y - \nu_{y0} = \frac{1}{2} (q - \nu_{x0} - \nu_{y0}) + \delta_x$

and Eq. (3-2) becomes
\[
\left[ \frac{1}{2} (q - \nu_{x0} - \nu_{y0}) \right]^2 - \delta_x^2 = |\Delta \nu_x|^2
\]

\[
\delta_x = \left\{ \left[ \frac{1}{2} (q - \nu_{x0} - \nu_{y0}) \right]^2 - |\Delta \nu_x|^2 \right\}^{1/2}
\] (4-7)

Eq. (4-7) gives $\nu_x$ in the stable region near the stopband. It can be put in another form that indicates the dependence on the distance from $\nu_{x0}, \nu_{y0}$ to the stopband edge.

Below the stopband, one writes
\[
\epsilon_x = q - 2|\Delta \nu_x| - \nu_x - \nu_{y0}
\] (4-8)

where $\epsilon_x$ indicates the distance from $\nu_x, \nu_y$ to the stopband edge which is given by Eq. (4-4). When $\nu_x, \nu_y$ is on the stopband edge and $\nu_{x0} + \nu_{y0} = q - 2|\Delta \nu_x|$ then $\epsilon_x = 0$.

Using Eq. (4-8) to replace $q - \nu_{x0} - \nu_{y0}$ by $\epsilon_x + 2|\Delta \nu_x|$ in Eq. (3-7) one finds
\[
\delta_x = \left\{ \epsilon_x (|\Delta \nu_x| + \epsilon_x/4) \right\}^{1/2}
\] (4-9)

Eq. (4-9) can then be written so as to hold both above and below the stopband to give
\[
\left| \nu_x - \frac{1}{2} (\nu_{x0} + q - \nu_{y0}) \right| = \left\{ \epsilon_x (|\Delta \nu_x| + \epsilon_x/4) \right\}^{1/2}
\]

\[
\epsilon_x = |q \pm 2|\Delta \nu_x| - \nu_{x0} - \nu_{y0}|
\] (4-10)

where $\epsilon_x$ is the distance from $\nu_{x0}, \nu_{y0}$ to the stopband edge. One uses the + sign for the upper stopband edge and the − sign for the lower edge.

Close to the stopband edge, where $\epsilon_x \ll |\Delta \nu_x|$ then Eq. (4-10) gives the result
\[
\left| \nu_x - \frac{1}{2} (\nu_{x0} + q - \nu_{y0}) \right| = \left\{ \epsilon_x |\Delta \nu_x| \right\}^{1/2}
\] (4-11)

Equations (4-10) and (4-11) give the tune of the $\nu_x$ mode, $\nu_x$, near the stopband edge. The result for the tune of the $\nu_y$ mode, $\nu_y$, may be found by making the substitution $\nu_x \to \nu_y$, $\nu_{x0} \to \nu_{y0}$, $\nu_{y0} \to \nu_{x0}$, $|\Delta \nu_x| \to |\Delta \nu_y|$. 
If one varies the unperturbed tune, \( \nu_{x0}, \nu_{y0} \), so that the tune approaches the edge of the stopband, the tune on the stopband edge depends on the value of \( \nu_{x0}, \nu_{y0} \) when the unperturbed tune arrives at the stopband edge. The stopband edges are given by the two lines

\[
\nu_{x0} + \nu_{y0} = q \pm 2|\Delta \nu|
\]

where it is assumed that \( |\Delta \nu_x| = |\Delta \nu_y| = |\Delta \nu| \) and the + sign is for the upper edge and the − sign for the lower edge.

The tune of the \( \nu_x \) mode at the stopband edge is then given by

\[
\nu_x = \frac{1}{2} \left( \nu_{x0} + q - \nu_{y0} \right)
\]

\[
\nu_x = \nu_{x0} \pm |\Delta \nu|
\] ii

(4-12)

where the + sign is for the lower edge and the − sign for the upper edge.

The tune of the \( \nu_y \) mode at the stopband edge is given by

\[
\nu_y = \nu_{y0} \pm |\Delta \nu|
\]

One may note, that at the stopband edge

\[
\nu_x + \nu_y = \nu_{x0} + \nu_{y0} \pm 2|\Delta \nu|
\]

\[
\nu_x + \nu_y = q
\]

(4-13)

and the \( \nu_x, \nu_y \) lies on the resonance line.

Eqs. (4-6) and (4-7) can also be rewritten as, for the \( \nu_x \) mode and below the resonance line,

\[
\nu_x = \nu_{x0} + 0.5D \left\{ 1 - \left[ \left( \frac{2\Delta \nu}{D} \right)^2 \right]^{\frac{1}{2}} \right\}
\]

\[
D = q - \nu_{x0} - \nu_{y0}
\]

\[
\Delta \nu = \Delta \nu_x \simeq \Delta \nu_y
\]

(4-14a)

The equation for the \( \nu_y \) mode is similar

\[
\nu_y = \nu_{y0} + 0.5D \left\{ 1 - \left[ \left( \frac{2\Delta \nu}{D} \right)^2 \right]^{\frac{1}{2}} \right\}
\]

(4-14b)

Using Eq. (4-14) one can compute how much \( \nu_x, \nu_y \) will move given the distance from the resonance, \( D \), and the stopband width \( \Delta \nu \). Eq. (4-14) show that as \( \Delta \nu \) is increased, \( \nu_x \)
and \( \nu_y \) will move along the line from \( \nu_{x0}, \nu_{y0} \) which is perpendicular to the resonance line. When \( \Delta \nu \) reaches 0.5 \( D \), \( \nu_x, \nu_y \) will arrive on the resonance line where \( \nu_x = \nu_{x0} + 0.5D \), \( \nu_y = \nu_{y0} + 0.5D \), \( \nu_x + \nu_y = q \).

5. The Beta Functions Near the Edge of a Stopband

In this paper it is being assumed that the unperturbed tune \( \nu_{x0}, \nu_{y0} \) is near the sum resonance \( \nu_{x0} + \nu_{y0} = q \), \( q \) an integer, and the other linear resonances are far enough away so that the particle motion is dominated by the sum resonance. For this case, it will be shown that the beta functions \( \beta_x, \beta_y \) do not become infinite when \( \nu_{x0}, \nu_{y0} \) approach the edge of the stopband, as was found \[2\] for the case of uncoupled particle motion near a half integer resonance. If one goes to a coordinate system where the coordinates are uncoupled, then \( \beta_x \) for the uncoupled coordinates can become infinite, when the tune of the \( \nu_x \) mode, \( \nu_x \) is close to a half integer resonance, \( \nu_x \simeq n/2 \), \( n \) being an integer. It is assumed here that \( \nu_{x0} \), and thus \( \nu_x \) is not near a half–integer resonance.

The beta functions, \( \beta_x, \beta_y \), for linearly coupled motion may be defined by going to the coordinate system where the new coordinates \( u, p_u, v, p_v \) are uncoupled. If the \( u, p_u \) motion goes over into \( x, p_x \) motion, when the coupling goes to zero, then the beta function of the \( u, p_u \) motion will be called \( \beta_x \). A similar definition is given to \( \beta_y \).

In section 2, a solution was found for \( \eta_x \), and \( x = \beta_{x0}^2 \eta_x \), when \( \nu_{x0}, \nu_{y0} \) are in the stable region near the edge of the stopband. \( \beta_x \) can be computed from this solution using the result, see section 6,

\[
\frac{1}{\beta_x} = \frac{1}{\nu_{x0} \beta_{x0}} \Im \frac{d}{d \theta_x} \log x
\]  

(5-1)

\( \Im \) stand for the imaginary part and \( \nu_{x0}, \beta_{x0} \) are the tune and beta function of the unperturbed motion. Eq. (5-1) holds for large accelerators. For small accelerators, where the large accelerator approximations are not used, it also requires that \( B_x = 0 \) on the closed orbit. Eq. (5-1) is derived in section 6.
The change in $\beta_x$ due to the linear coupling field may be computed using Eq. (5-1) and the solution for $x = \beta_x^2 \eta_x$ found in section 3, Eq. (3-14),

$$\eta_x = A_s \exp (i \nu x_0 \theta_x) \left[ 1 + \sum_{m \neq 0} f_m \exp (-im \theta_x) \right]$$

$$f_m = \frac{-2 \nu x_0}{m (m - 2 \nu x_0)} d_x b_m \exp (-i \delta_1 x)$$

$$d_x = \frac{-|\Delta \nu_x|}{\frac{1}{2} (q - \nu x_0 - \nu y_0) + \delta_x}$$

$$b_m = \frac{1}{4 \pi} \int \frac{ds a_1}{\rho} (\beta_x \beta_y)^{1/2} \exp [-i ((q - \nu x_0) \theta_y + \nu x_0 \theta_x) + im \theta_x]$$

$$\Delta \nu_x = \beta_0, \quad \delta_1 x = ph (\Delta \nu_x)$$

In the stable region, near a stopband edge, $\delta_x$ is given by

$$|\delta_x| = \{ \epsilon (|\Delta \nu_x| + \epsilon/4) \}^{\frac{1}{2}}$$

$$\epsilon = |q + \pm |2 \Delta \nu_x| - \nu x_0 - \nu y_0|$$

with the ± sign for the upper and lower edge, respectively. $\nu_{xs}$ has been replaced by $\nu_x$ and $\delta_x$ is positive for the lower edge and negative for the upper edge. One then gets

$$Im \frac{d}{d \theta_x} \log x = \nu_x + Im \sum_{m \neq 0} (-im f_m \exp (-im \theta_x))$$

$$\frac{1}{\beta_x} = \frac{1}{\nu x_0 \beta x_0} \left( \nu_x - Re \sum_{m \neq 0} m f_m \exp (-im \theta_x) \right)$$

$$\frac{1}{\beta_x} = \frac{1}{\beta x_0} \left( 1 + \frac{\nu_x - \nu x_0}{\nu x_0} - \frac{1}{\nu x_0} Re \sum_{m \neq 0} m f_m \exp (-im \theta_x) \right)$$

$$\beta_x = \beta x_0 \left( 1 - \frac{\nu_x - \nu x_0}{\nu x_0} + \frac{1}{\nu x_0} Re \sum_{m \neq 0} m f_m \exp (-im \theta_x) \right)$$

$$\frac{\beta_x - \beta x_0}{\beta x_0} = -\frac{\nu_x - \nu x_0}{\nu x_0} + \frac{1}{\nu x_0} Re \sum_{m \neq 0} m f_m \exp (-im \theta_x)$$

The results for $(\beta_x - \beta x_0)/\beta x_0$ is then

$$\frac{\beta_x - \beta x_0}{\beta x_0} = -\frac{\nu_x - \nu x_0}{\nu x_0} - \sum_{m \neq 0} \frac{2}{m - 2 \nu x_0} d_x Re (b_m \exp (-im \theta_x - i \delta_1 x))$$
If one assumes that the harmonic $m \simeq 2\nu_{x0}$ dominate then the maximum change in $\beta_x$ may be approximated by

$$\left| \frac{\beta_x - \beta_{x0}}{\beta_{x0}} \right|_{\text{max}} = \left| \frac{\nu_x - \nu_{x0}}{\nu_{x0}} \right| + \frac{2|d_x| b_m}{|m - 2\nu_{x0}|} \quad (5-6)$$

$\nu_x$ is given by Eq. (4-10).

The results for $\beta_y$ may be found by replacing each parameter with the corresponding parameter for the $\nu_y$ mode.

6. Small Accelerator Results

All the final results found in this paper will also hold for small accelerators where the exact equations of motion have to be used. The exact linear equations have the form [1]

$$\frac{dx_i}{ds} = \sum A_{ij} x_j, \quad (6-1)$$

where $i, j$ for from 1 to 4 and the $x_i$ are the coordinates $x, p_x, y, p_y$. For large accelerators $p_x \simeq dx/ds, p_y \simeq dy/ds, A_{11} = A_{22} = A_{33} = A_{44} = 0$, and $A_{12} = A_{34} = 1$. The $A_{ij}$ for the exact equations are given in reference 1. In particular

$$A_{12} = \frac{(1 + x/\rho) (1 - p_y^2)}{p_s^3}, \quad A_{34} = \frac{(1 + x/\rho) (1 - p_x^2)}{p_s^3}$$

$$A_{13} = 0, \quad A_{14} = \frac{(1 + x/\rho) p_x p_y}{p_s^3} \quad (6-2)$$

$$p_s = \{1 - p_x^2 - p_y^2\}^{\frac{1}{2}}$$

where the right hand side in the equation for $A_{ij}$ are evaluated on the closed orbit.

The linear differential equations for $\eta_x$ and $\eta_y, \eta_x = x/\beta_{x0}^{\frac{1}{2}}, \eta_y = \nu/\beta_{y0}^{\frac{1}{2}}$ can be found [1] as

$$\frac{d^2}{d\theta_x^2} \eta_x + \nu_{x0}^2 \eta_x = f_x$$

$$\frac{d^2}{d\theta_y^2} \eta_y + \nu_{y0}^2 \eta_y = f_y$$

$$f_x = \frac{\nu_{x0}^2 \beta_{x0}^{3/2}}{A_{12}} (1 + x/\rho) \Delta B_y$$

$$f_y = -\frac{\nu_{y0}^2 \beta_{y0}^{3/2}}{A_{34}} (1 + x/\rho) \Delta B_x$$

$$d\theta_x = A_{12} ds/\nu_{x0} \beta_{x0}, \quad d\theta_y = A_{34} ds/\nu_{y0} \beta_{y0}$$

$$\frac{\nu_{x0}^2 \beta_{x0}^{3/2}}{A_{12}} (1 + x/\rho) \Delta B_y$$

$$f_y = -\frac{\nu_{y0}^2 \beta_{y0}^{3/2}}{A_{34}} (1 + x/\rho) \Delta B_x$$

$$d\theta_x = A_{12} ds/\nu_{x0} \beta_{x0}, \quad d\theta_y = A_{34} ds/\nu_{y0} \beta_{y0}$$
\( \Delta B_x, \Delta B_y \) are the perturbing fields given by Eqs. (2-1). For small accelerators, in order for Eqs. (6-3) to be valid, one also requires that the perturbing fields do not shift the closed orbit, or \( \Delta B_x = \Delta B_y = 0 \) on the closed orbit. If the closed orbit is shifted by the perturbing field, then the non-linear kinematic terms, the terms which do not explicitly depend on the field, will generate additional linear terms. \( \nu_{x0}, \nu_{y0}, \beta_{x0}, \beta_{y0} \) are the tune and beta functions of the unperturbed accelerator.

Comparing Eqs. (6-3) with the corresponding equations for large accelerators, Eqs. (2-2) one notes that \( f_x \) and \( f_y \) for the small accelerator have the additional factors of \( 1/A_{12} \) and \( 1/A_{34} \) respectively. Although the perturbation terms in Eqs. (6-3) now have the extra factors \( 1/A_{12} \) and \( 1/A_{34} \), these factors disappear in the final results when in the relevant integrals one goes from the variables \( \theta_x \) or \( \theta_y \) to the variable \( s \) according to Eqs. (6-3). Using Eqs. (6-3) one can go through the derivations and show that the final results for the tune, growth rates and beta functions are valid for both large and small accelerators.

One thing that remains to be done is to derive Eq. (5-1),

\[
\frac{1}{\beta_x} = \frac{1}{\nu_{x0}\beta_{x0}} Im \frac{d}{d\theta_x} ln x
\]  

(6-4)

which allows \( \beta_x \) to be computed from the solutions for \( \eta_x, \eta_y \).

The beta functions \( \beta_x, \beta_y \) for linearly coupled motion may be defined by going to the coordinate system where the near coordinates \( \mu, \mu_u, v, v_u \) are uncoupled. If the \( \mu, \mu_u \) motion goes into the \( x, p_x \) motion when the coupling goes to zero, then the beta function of the uncoupled \( \mu, \mu_u \) motion will be called \( \beta_x \). The solution of the equations of motion for \( \mu, \mu_u \) may be related to \( \beta_x \) by [1]

\[
\mu = C\beta_x^{\frac{1}{2}} \exp(i\psi_x) \\
p_u = C\beta_x^{-\frac{1}{2}} \exp(-\alpha_x + i) \exp(i\psi_x)
\]  

(6-5)

\( C \) is a normalization constant. \( x, p_x \) and \( \mu, p_u \) are related by the decoupling matrix, \( R \) [3]

\[
\begin{pmatrix}
x \\
p_x \\
y \\
p_y
\end{pmatrix} = R
\begin{pmatrix}
u \\
p_u \\
v \\
p_v
\end{pmatrix}
\]  

(6-6)

\[
R = \begin{pmatrix}
cos \phi I & D \sin \phi \\
-D^{-1} \sin \phi & cos \phi I
\end{pmatrix}
\]
$I$ is the $2 \times 2$ identity matrix and $D$ is a $2 \times 2$ matrix and $|D| = 1$. One then finds

$$x = C\beta_x \frac{\partial}{\partial x} \exp(i\psi_x)$$

$$p_x = C\beta_x \frac{\partial}{\partial x} \exp(i\psi_x)$$

(6-7)

From Eq. (6-7) one can relate $\beta_x$ to $x, p_x$ solutions by

$$\frac{1}{\beta_x} = \text{Im}(p_x/x)$$

(6-8)

where $\text{Im}$ is the imaginary part. $p_x$ may be eliminated by using Eq. (6-1)

$$p_x = \frac{1}{A_{12}} \left( \frac{dx}{ds} - A_{11} x - A_{13} y - A_{14} p_y \right)$$

which gives

$$\frac{1}{\beta} = \text{Im} \left[ \frac{1}{x A_{12}} \left( \frac{dx}{ds} - A_{11} x - A_{13} y - A_{14} p_y \right) \right]$$

(6-9)

In the large accelerator approximation, $A_{12} = 1$ and $A_{13} = A_{14} = 0$ and (6-9) gives

$$\frac{1}{\beta} = \text{Im} \frac{d}{d\theta_x} \log x$$

(6-10)

For small accelerators, one has (see reference 1)

$$A_{13} = \frac{\partial}{\partial y} \left[ \frac{(1 + x/\rho) p_x}{p_s} \right] = 0$$

$$A_{14} = \frac{\partial}{\partial p_y} \left[ \frac{(1 + x/\rho) p_x}{p_s} \right] = (1 + x/\rho) \frac{p_x p_y}{p_s^3}$$

(6-11)

$$p_s = [-1 - p_x^2 - p_y^2]^{1/2}$$

Thus if $\Delta B_x = 0$ on the closed orbit, so that $p_y = 0$ on the closed orbit then $A_{14} = 0$ for small accelerators too. Since $A_{12} ds = \nu x_0 \beta x_0 d\theta_x$, one gets Eq. (6-10) again for small accelerators provided $\Delta B_x = 0$ on the unperturbed closed orbit.
7. Comments on the Results

Others have worked on this subject and there is an overlap between the contents of this paper and their work. These previous papers (4 to 12) give results for the stopband width and for the growth rate inside the stopband.

The results in this paper include the following:

1. Results for the tune in the stable region near an edge of the stopband. The results show that as $\nu_x^0$, $\nu_y^0$ approach the edge of the stopband, the tunes of the two normal modes $\nu_x$ and $\nu_y$ begin to change rapidly and when $\nu_x^0$, $\nu_y^0$ reach the stopband edge then $\nu_x$ and $\nu_y$ lie on the resonance line $\nu_x + \nu_y = q$. These final values of $\nu_x$, $\nu_y$, when $\nu_x^0$, $\nu_y^0$ reach the stopband edge, are approached like $\epsilon^{1/2}$, where $\epsilon$ is the distance from $\nu_x^0$, $\nu_y^0$ to the stopband edge.

2. Results for the beta functions of the normal modes, $\beta_x$, $\beta_y$, in the stable region near the edge of a stopband. The results show that $\beta_x$, $\beta_y$ do not become infinite when $\nu_x^0$, $\nu_y^0$ approach the stopband edge, unless $\nu_x^0$, $\nu_y^0$ are near the half integer resonances $v_x = m/2$, or $v_y = n/2$, $m$ and $n$ being integers.

3. Results for the 2 solutions of the equations of motion in the stable region near a stopband edge and in the unstable region.

4. The above results hold also for small accelerators, where the exact equations of motion have to be used and the large accelerator approximation is not valid. For small accelerators, one needs the restriction that the perturbing field gradients do not shift the closed orbit.
