Abstract
Tilt angle optimization of the solar collector is essential to achieve maximum power output. In this study, the performance analysis of monthly and yearly optimum tilt angles has been carried out for solar power plant setup-able sites in the Western Himalayan region of India. A mathematic model has been used for optimum tilt angle assessment. Annual average performance enhancement for monthly optimum tilt angles is 10–11%, 5–7% and 4–6% from horizontal, tilted at the latitude and tilted at an optimum tilt angle, respectively. Validation of the results has been carried out by mounting a polycrystalline PV panel at one of the suggested plant setup-able sites (ϕ30° 51’ 1.656”, L 77° 3’ 41.508”). The percentage variations found in experimental results are 8.85, 9.13 and 14.09 from horizontal, tilted at the latitude and tilted at yearly optimum tilt angle PV panel, respectively. To generalize the obtained result, correlations in terms of latitude and declination angle have also been formulated for yearly and monthly optimum tilt angles, respectively. The preciseness of the developed correlations has been validated by statistical tools. The results from this study have also been compared with the results of some previous studies, and good agreement has been obtained.

Introduction
Energy is essential for every living being to sustain life. Conventional methods of electricity generation have many disadvantages that can be eradicated by utilizing renewable
energy resources. Among the renewable energy resources, solar energy is available in abundance and has a very large scope specifically in India [1–4]. About 58% of India’s geographical area is incident by 5 kWhm−2 day−1 solar insolation [5]. National Solar Mission (NSM) has been launched in India on January 11, 2010, with a target of developing 20 GW of solar power by 2022 which is further revised on June 17, 2015, to increase the target to 100 GW from 20 GW. As of December 31, 2017, 17,052 MW of solar power is being developed in India [6]. Thus, India has a very vast opportunity for solar energy which is being mined at surging speeds. Solar energy can be directly converted into conventional forms of energy, i.e., thermal as well as electrical energy [7, 8]. Direct or indirect energy gains from solar radiation (global radiations) are integrated with active or passive heating systems. These systems aim to preserve energy sustainability and minimize heat losses. Experimental, theoretical and numerical research has been done in the literature on photovoltaic systems, solar still desalination systems, building-integrated photovoltaic systems (BIPV), building-integrated photovoltaic thermal (BIPVT) and solar water heater system [9, 10]. One of the major complications with solar energy collection is that the solar radiations do not fall perpendicularly to the surface of the earth. In order to overcome this restraint, solar collectors are tilted to some angle which is called tilt angle. These tilt angles are a function of latitude and declination angle and have a very large impact on the total energy collection rate [11]. So, the potential of solar energy can be maximized by solar collector tilt angle optimization.

Various studies have been reported in the literature for solar collector tilt angle optimization and their related consequences. Calabro [12] developed an algorithm for optimum tilt angle determination and found that optimum tilt angle is a function of latitude angle at any location. Thakur and Chandel [13] calculated and implemented optimum tilt angle on 190 kWp grid-interactive solar power plant and found that total increase in energy yield is 25%, 28% and 29% at yearly, seasonal and monthly optimum tilt angles, respectively, in comparison with the fixed tilt angle of the plant. Awasthi et al. [14] evaluated the optimum tilt angle for latitude at Himachal Pradesh, India. The authors also formulated annual adjustment models for the practical implementation of these models. Authors reported that from the conventional system of setting the solar collector at a latitude angle, the system performance improved by 5.51%. Optimization of slope angle for two distinctive temperature regions of Iran to maximize the solar radiations was carried out by Abdolzadeh and Mehrabian [15]. An annual increment in performance of the solar collector of 7–8% for selected sites at monthly optimum tilt angles was reported by the authors. Similarly, Benghanem [16] calculated the monthly optimum tilt angles for Madinah, Saudi Arabia. De Bernardez et al. [17] utilized a distinguishing approach for yearly and monthly optimum tilt angle determination at Argentina using neural networks. Abdulsalam et al. [18] carried out a study for solar insolation estimation for different models at Dhahran city, Saudi Arabia. The results revealed that the performance-enhanced through different models were 7%, 14%, 33% and 48% for yearly optimum, monthly optimum, single-axis and double-axis, respectively, in comparison with the horizontal solar collector. In another study, Soulayman and Sabbagh [19] computed tilt angle for tropical regions. An increment of 11–18% from the conventional method was reported in the study. The authors also revealed that the radiation received over solar collector tilted at monthly optimum tilt angle is approximately equal to the solar collector tilted at a daily optimum tilt angle. Siraki and Pillay [20] computed optimum tilt angles for different urban areas at different latitudes and found that tilt angle is a function of obstacles in an urban area also. The aforementioned studies demonstrate the optimum tilt angle assessment necessity for maximum solar radiation collection. For estimation of insolation over tilted solar collector, either isotropic or anisotropic models of solar radiation distribution are utilized [21, 22]. The incorrect results might be obtained by the inappropriate choice of these models and other assumptions. So for validation of obtained results, an experimental investigation is generally adopted by the researchers [23–25]. This signifies the importance of experimental validation of analytically obtained optimum tilt angle.

To generalize the obtained optimum tilt angle for a particular or range of latitudes, correlation development has been carried out by various scholars. As mentioned earlier, the tilt angle is a function of the latitude of a place and the declination angle of the year. Thereby, the reported correlations for optimum tilt angles are either dependent on latitude or declination angle. It has also been observed that the correlations developed for yearly optimum tilt angle are in terms of latitude angle and for monthly optimum tilt angles in declination or extraterrestrial solar radiations. Wessley et al. [26] formulated a mathematical model for optimum tilt angle for some Indian cities and developed a correlation for yearly optimum tilt angle based on latitude. In another study, Yadav and Chandel [27] evaluated optimum tilt angle for 26 cities of India and developed a yearly optimum tilt angle correlation as a function of latitude. Yadav and Malik [28] estimated the monthly optimum tilt angle for six Indian sites and developed a correlation in terms of declination angle. Similarly, many other researchers developed correlations for monthly and yearly optimum tilt angles at various latitudes [29, 30].

The aforementioned studies on solar collector tilt angle optimization are equally effective for small and large solar energy collection units. However, their significance increases with the increasing capacity of the solar power
Solar collector tilt angle optimization for solar power plant setup-able sites at Western…

plants. The site for a large solar power plant setup should be selected afterward its qualification around some criteria. A significant amount of land area is required for setting up a solar power plant. Chandel et al. [31] suggested that for installing 2.5 MW plant space required is almost 13.14 acres (1 acre = 4047 m²). Solar power plants can be installed in moderately hilly regions without any obstacles like a tree, scrub, etc. Additionally, it is also non-beneficiary to setup a solar power plant by decapitation of forests. Most of the recently presented studies on optimum tilt angle determination are carried out for urban areas without considering the suitability of the solar power plant. Therefore, sites for tilt angle optimization should be selected where chances are supreme and favorable for setting up a solar power plant in near future.

The literature survey suggests that the solar collector tilt angle optimization and site selection significantly affect the radiation collection rate and capacity of the solar power plants, respectively. However, most of the studies for tilt angle optimization have been reported for urban areas which are inappropriate for setting up solar power plants. So, the first objective of this study is to identify solar power plant setup-able sites in the Western Himalayan region of India. After site selection, the second objective is to evaluate the optimum tilt angle at monthly and yearly levels for the identified sites and their performance analysis. The isotropic diffuse radiation model has been utilized for evaluating the optimum tilt angle values. The literature review also suggests that the experimental validation of the analytically obtained optimum tilt angle is necessary for flawless predictions and operations. So, experimental validation of the obtained results at one of the selected sites is the third objective. Lastly, the correlation postulations for optimum tilt angles and their statistical analysis is the final objective of the current work. The detailed methodology for achieving the mentioned objectives has been presented in the next section.

Methodology

Site selection and data assemblage

The Himalayas are the mountain range in southern Asia extending in India, Nepal, Pakistan, Afghanistan, Bhutan and China. Himachal Pradesh is a northern state of India which lies in the Western Himalayan region. The state has a significant amount of solar energy potential of 33.84 GWp [32]. Himachal Pradesh is a hilly region with an altitude range from 450 to 7026 m above sea level, and according to a forest survey of India, 27.12% area of Himachal Pradesh is forest covered [33]. So, in this study, nine such sites have been selected in Himachal Pradesh which can be used for solar power plant installation. The criterion for the selection of these sites is open scrub, degraded forest and barren rocky land. The types of land have been identified by the data provided by the waste-land maps from the Department of Land Resources, India (Fig. 1a) [34]. These sites with their coordinates, i.e., latitude and longitude along with the type of land areas, are shown in Table 1. These sites have been selected by local surveys and satellite image surveys on Google Maps [35]. The geographical locations of these sites are presented on the map in Fig. 1b. The Surface meteorology and Solar Energy (SSE) datasets provided by the National Aeronautics and Space Administration (NASA) [36] have been

![Map of India](image1.png)

**Fig. 1** a Wasteland map of Himachal Pradesh, b locations of selected sites on a geographical map

---

*Springer*
used for the data curation of solar radiation on the horizontal plane (kWh m\(^{-2}\) day\(^{-1}\)). The SSE provides \(10 \times 10\) (\(\approx 100 \times 100\) km) spatial resolution data on a global grid with temporal coverage of solar radiation parameters for 22 years [37]. Global insolation data for the last four years have been taken for particular latitudes (\(\phi\)). The monthly average of insolation data taken from SSE datasets for the 4 years (2014–2017) is shown in Table 2. Table 2 represents the variation in insolation for different sites at different months of the year and annual average insolation.

Optimum tilt angle assessment

The position of the sun changes over any specific location on earth throughout the year and even throughout the day because of the rotary and revolutionary motion of the earth around its axis and sun, respectively. Figure 2 represents the geometry of solar trajectory over a tilted surface placed over the earth’s surface along with different associated angles.

Global insolation on a tilted surface (\(H_{g,t}\)) is an aggregation of three solar radiation components, i.e., direct, diffuse and reflected radiations. The \(H_{g,t}\) can be calculated by Eq. 1 [38]:

\[
H_{g,t} = H_{d,t} + H_{d,t}^{\text{diffuse}} + H_{r,t}^{\text{reflected}}
\]
$H_{g,t}(\text{KWhm}^{-2}\text{day}^{-1}) = (H - H_d)R_B + H_d \left( \frac{1 + \cos \beta}{2} \right) + H \cdot \rho_d \left( \frac{1 - \cos \beta}{2} \right).$  

(1)

This shows that global insolation on the tilted surface is a function of global insolation on a horizontal surface ($H$), the ratio of the beam radiation on a tilted and horizontal surface ($R_B$), diffuse radiation on a horizontal surface ($H_d$), reflection factor ($\rho_d$) and tilt angle ($\beta$). Various models have been suggested in the literature for the estimation of diffuse radiation. Yadav and Chandel [27] investigated diffuse radiation estimation using different models at a northern location in India, and the results reveal that the isotropic diffuse radiation model suggested in the literature for the estimation of diffuse radiation has been used in the present study.

Data for global insolation on a horizontal surface ($H$) have been taken from the SSE datasets provided by NASA; $R_B$ can be expressed as Eq. 2 [13],

$$R_B = \frac{\cos \theta}{\cos \theta_Z} = \frac{\cos(\phi - \beta) \cos \delta \sin \omega_s + \omega_s \sin(\phi - \beta) \sin \delta}{\cos \delta \sin \phi \cos \delta + \omega_s \sin \phi \sin \delta}$$

(2)

where $\theta, \theta_Z, \delta$ and $\omega_s$ are incidence angle, zenith angle, declination angle and sunset angle, respectively. The expressions for calculating $\delta$ and $\omega_s$ are as follows [40],

$$\delta = 23.45 \sin \left( \frac{360}{365} \left( 284 + n \right) \right)$$

(3)

$$\cos \omega_s = - \frac{\sin \phi \sin \delta}{\cos \phi \cos \delta} = - \tan \phi \tan \delta$$

(4)

$H_d$ is a function of the clearness ratio ($kT$) and $H$. $H_d$ is given by,

for $\omega_s \leq 81.4^\circ$

$$H_d = 1.391 - 3.56k_T + 4.189k_T^2 - 2.137k_T^3$$

and for $\omega_s \geq 81.4^\circ$

$$H_d = 1.311 - 3.022k_T + 3.427k_T^2 + 1.821k_T^3$$

(5)

where, $k_T = H/H_0$, $H_0$ is extraterrestrial radiations on a horizontal surface, and for any Julian day ($n$) of the year, it is evaluated as Eq. 6, where $G_{SC}$ is the global solar constant ($G_{SC} = 1367 \text{ Wm}^{-2}$) [22].

$$H_o(\text{KWhm}^{-2}\text{day}^{-1}) = 24 \times G_{SC} \left( 1 + \left( 0.033 \cos \left( \frac{360n}{365} \right) \right) \right)$$

(6)

The optimum value of $\beta$ lies in the range of $0^\circ \leq \beta \leq 90^\circ$. Therefore, for finding the optimum tilt angle corresponding to maximum $H_{g,t}$ for a particular latitude, the value of $\beta$ has been varied from 0 to 90 degrees. Performance enhancement (PE) of the solar collector tilted at $\beta_{\text{opt, monthly}}$ from otherwise tilted is expressed by Eq. 7.

$$\text{PE}(\%) = \left( \frac{(H_{g,t})_{\beta_{\text{opt,monthly}}} - (H_{g,t})_{\beta}}{(H_{g,t})_{\beta_{\text{opt,monthly}}}} \right) \times 100$$

(7)

Experimental validation

The experimental analysis has been conducted at one of the selected sites [Kalth ($\phi = 30.85^\circ$, $L = 77.06^\circ$)] to validate the obtained analytical results of optimum tilt angle. A polycrystalline PV panel fixed on a tilt-able stand facing toward the true south has tilted at different angles. The tilt-able stand was designed to fix four options of horizontal, latitude, yearly optimum and monthly optimum tilt angles. Specifications of the PV panel used for experimental validation are shown in Table 3. A pictographic view of the tilt-able panel and circuit diagram is shown in Fig. 3.

Hourly data for open-circuit voltage ($V_{OC}$) and short-circuit current ($I_{SC}$) have been recorded. Power output ($P_O$) from the panel is recorded as Eq. 8,

$$P_O = V_{OC} \times I_{SC}$$

(8)

Percentage gain in power output is termed as power output performance enhancement (POPE) and calculated by Eq. 9.

$$\text{POPE} = \left( \frac{(P_O)_{\beta_{\text{opt,monthly}}} - (P_O)_{\beta}}{(P_O)_{\beta_{\text{opt,monthly}}}} \right) \times 100$$

(9)

POPE at a particular location and time represents PE. So, to validate the obtained results the PE has been compared with POPE and percentage variation is calculated by Eq. 10.

| Parameter                  | Units | Magnitude |
|----------------------------|-------|-----------|
| $P_{\text{max}}$           | W     | 74        |
| Voltage ($V_{\text{max}}$) | V     | 18        |
| Current ($I_{\text{max}}$) | A     | 4.25      |
| Open-circuit voltage ($V_{OC}$) | V | 21        |
| Short-circuit current ($I_{SC}$) | A | 4.55      |
| Bypass diode rating        | A     | 8         |
| System voltage             | V (DC)| 1000      |
| Safety class               | –     | II        |
This percentage variation has been used as a validating tool for this study.

\[
\text{Percentage Variation} = \left( \frac{(PE)_{\theta} - (POPE)_{\theta}}{(PE)_{\theta}} \right) \times 100
\]  

(10)

Correlations for optimum tilt angles

The current section discusses the methodology adopted for correlation formulation. The calculation part consists of two stages. The first stage includes the formulation of three mathematical models for optimum tilt angle estimation as a function of the declination angle of the selected sites. Declination angle is computed by Eq. 3; as is known, it changes by the rotation of the earth around the sun. Table 4 shows the recommended monthly declination angle value corresponding to the Julian days. The latitude of sample cities that were used in the calculation is between 30° 30′ N- (lowest) and 33° 6′ N (highest). Therefore, mathematical models (Eqs. 15–17) have been established based on the declination angle which can completely answer the selected area.

In the second stage, three different mathematical correlations for yearly optimum tilt angle based on latitude have been developed. The yearly optimum tilt angle of any site in the selected latitude range can be calculated utilizing the established equations. The accuracy of the developed correlations from stages 1 and 2 has been checked using the statistical comparison methods.

Statistical methods

The investigation of the correlation accuracy is necessary for increasing the frequent usability of the developed mathematical models. Literature has demonstrated numerous methods to determine the statistical accuracy of developed equations. The most commonly used methods are mean bias error (MBE), root-mean-square error (RMSE) and t-statistics (t-sat). The main goal of these methods is to find the usability and accuracy of mathematical correlations [40, 41]

| Months | Jan. | Feb. | Mar. | Apr. | May | Jun. | Jul. | Aug. | Sep. | Oct. | Nov. | Dec. |
|--------|------|------|------|------|-----|------|------|------|------|------|------|------|
| Day of the year | 17 | 47 | 75 | 105 | 135 | 162 | 198 | 228 | 258 | 288 | 318 | 344 |
| Date | 17 | 16 | 16 | 15 | 15 | 11 | 17 | 16 | 15 | 15 | 14 | 10 |
| Declination (\(\delta\)) | −20.92 | −13.29 | −2.42 | 9.41 | 18.79 | 23.09 | 21.18 | 13.45 | 2.22 | −9.60 | −18.91 | −23.05 |

Fig. 3 Circuit diagram (a) and pictographic view (b) of the experimental setup
MBE informs on long-term values of correlation. Minimum value implies more effectiveness of correlation, and the ideal value is being close to zero. It is calculated by Eq. 11. \( ci \) (calculated) in the equation represents the computed value; \( mi \) (measured) shows the measured value.

\[
MBE = \frac{1}{n} \sum_{i=1}^{n} (mi - ci)
\]

(11)

The RMSE is a statistical tool that has importance in terms of comparing both short-run measured and estimated performance. It always takes a positive value. The most ideal value is closest to zero. It is expressed by Eq. 12.

\[
RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (ci - mi)^2}
\]

(12)

The t-test method (t-stat) is decided whether the difference between the t-test and the average of two groups is accidental or statistically rational [42]. It is shown in Eq. 13.

\[
t - stat = \sqrt{\frac{(n - 1)MBE^2 - \beta^2}{RMSE^2 - \beta^2}}
\]

(13)

The power of connection between two variables can be evaluated using the determination coefficient \( R^2 \). It is used to specify the linear relationship between computed and measured data. The value of this coefficient varies between 0 and 1 (0 < \( R^2 < 1 \)), and the most ideal value is the closest to zero. It is expressed by Eq. 14; \( ca \) and \( ma \) are the averages of, respectively, computed and measured values.

\[
R^2 = \frac{\sum_{i=1}^{n} (ci - ca)x(mi - ma)}{\sqrt{\sum_{i=1}^{n} (ci - ca)^2} \times \sqrt{\sum_{i=1}^{n} (mi - ma)^2}}
\]

(14)

\section*{Results and discussion}

\subsection*{Tilt angle assessment and performance enhancement}

Monthly optimum tilt angles for selected sites have been computed utilizing Eq. 1–7. Figure 4 shows the radiation intensity corresponding to the different tilt angles (0°–90°) for selected sites. The results depict that the optimum tilt angles corresponding to the maximum solar radiations lie in the range of 0–56° for all the selected sites. The highest optimum tilt angle values can be observed in December-January, while the lowest values are in May–July. While solar panel tilt angle values are in a decreasing trend in the period from December to June, it tends to increase in the period from June to December. In the northern hemisphere, the sun’s rays come at the right angle on June 21, while the opposite happens on December 21 at the maximum oblique angle as a result of the annual movement of the earth. The tilt angle which facilitates maximum insolation has been selected as \( \beta_{opt, monthly} \). The result depicts that the monthly optimum tilt angle \( \beta_{opt, monthly} \) varies from 47° to 55° in January, 43°–48° in February, 31°–37° in March, 16°–19° in April, 0° for May–July, 8°–10° degrees for August, 27–30° in September, 44°–48° in October and 51°–56° in November and December for all the selected solar plant setup-able sites. The range of monthly optimum tilt angles for different sites is shown in Fig. 5. It is generally known by researchers that the optimum slope depends on the latitude and day of the year. Throughout the year, the panel inclination angle is taken equal to latitude \( (\phi) \); it is taken more than latitude \( (\phi + 15) \) in winter and lower than latitude \( (\phi - 15) \) in summer [38, 43, 44]. Figure 6 shows the solar radiations corresponding to solar collector tilted at annual average, latitude, horizontal and monthly optimum for all regions. The figure depicts that the solar collector tilted at monthly optimum tilt angle receives maximum solar radiations as compared to other positions. Performance enhancement (PE) of the tilted solar collectors to \( \beta_{opt, monthly} \), is measured by comparing it with horizontal, tilted at the latitude and tilted at yearly optimum tilt angle solar collectors. Equation 8 is utilized for the comparison, and the results are presented in supplementary data.

The PE is maximum in October–March and minimum in April–August from the horizontally aligned solar collector. This is because the optimum tilt angle for April–August is very small approaches toward zero. PE for \( \beta = 0° \) and \( \beta_{opt, yearly} \) is minimum (< 5%) in March–April and August–October. Annual average percentage performance enhancement (AAPPE) is plotted in Fig. 7 which follows the order of (AAPPE) \( \beta = 0° > (AAPPE)\beta = \phi > (AAPPE)\beta = \beta_{opt, yearly} \) for all the selected sites. This shows that PE is maximum from \( \beta = 0° \) then \( \beta = \phi \) and least from \( \beta = \beta_{opt, yearly} \). So, for collecting maximum solar radiations, the solar collector should be tilted in order of, \( \beta_{opt, monthly} > \beta_{opt, yearly} > (\beta = \phi) > (\beta = 0°) \).

\subsection*{Experimental validation}

Validation of the obtained results has been carried out by adjusting the tilt angle of a PV panel to different positions at one of the selected locations, i.e., Kalth (\( \phi 30° 51′ 1.656^\circ \), L 77° 3′ 41.508\(^\circ\)). Experimentation has been carried out from 17/03/2019 to 31/03/2019, and data have been recorded for open-circuit voltage \( (V_{OC}) \) and short-circuit current \( (I_{SC}) \) of the PV panel. PV panel has been tilted to four positions, \( \beta_{opt, monthly} \) (i.e., 37°), \( \beta_{opt, yearly} \), i.e., 28.83°, \( \phi \), i.e., 30° 51′ 1.656\(^\circ\), and horizontal (0°). Daily variation in average
The variation among POPE and PE can be justified as differences (i.e., <15% variation) to the proposed numerical results. These results are found very much closer compared with the computed PE values at Kalth. Table 6 represents the comparison of POPE and PE. The percent-age variation (from Eq. 11) of the POPE from PE for a particular month, and to validate the results the POPE is compared with the computed PE values at Kalth. Table 6 gives the comparison of POPE and PE. The percentage variation (from Eq. 11) of the POPE from PE for $\beta=0^\circ$, $\beta=\phi$, and $\beta=\beta_{\text{opt,yearly}}$ is 8.84%, 9.13% and 14.05%, respectively. These results are found very much closer (i.e., <15% variation) to the proposed numerical results. The variation among POPE and PE can be justified as differences in climatic conditions and losses at particular tilt positions of the PV panel. Figure 8 shows that PO of PV panel tilted at $\beta_{\text{opt}}$ monthly goes on decreasing comparatively.

Fig. 7  Annual average percentage performance enhancement (AAPPE) for selected sites
as we proceed to the end of the month. This trend is due to the fact that \( \beta_{\text{opt, monthly}} \) for April is smaller, i.e., 17\(^\circ\). The trend for power output from PV panels tilted at latitude is of domed shape which increases for the first few days and decreases in some last days. For PV panels tilted at \( \beta_{\text{opt, yearly}} \), yearly, PO shows the almost same trend as tilted at latitude angle because of a very small difference among latitude and yearly optimum tilt angles. For horizontal PV panel, the daily average power output is increasing gradually because the optimum tilt angle approaches toward \( \beta_{\text{opt, monthly}} \) of April.

### The correlations for solar collector optimum tilt angles

The correlations have been developed for the monthly and yearly optimum tilt angles for the selected sites in order to generalize the obtained results. Initially, the linear, second-degree polynomial and third-degree polynomial correlations were developed by using the declination angle (\( \delta \)) for the monthly optimum tilt angle at the Kalth. Equations 15–17 represent the developed correlations for linear, second-degree and third-degree polynomial, respectively. The results are presented in Fig. 9a.

\[
\beta_{\text{opt, monthly}} = -1.2949(\delta) + 28.365
\]  

(15)
The practicality of monthly optimum tilt angle is depreciated due to tediousness and cost involvement. This difficulty can be overcome by yearly optimum tilt angle up to some extent. So, three different mathematical models based on latitude were developed to determine the yearly optimum solar collector tilt angle. Equations 18–20 used for a selected range of latitude (30° 30′ ≤ ϕ ≤ 33° 6′) as seen in Fig. 9b. The yearly optimum solar panel tilt angle can be estimated based on the latitude using these mathematical models. The next section discusses the statistical analysis of these developed models.

### Statistical analysis for developed models

Table 7 statistically shows the success of mathematical models to estimate monthly and yearly optimum angles. Estimation equations that give best results in terms of $R^2$ (determination coefficient), respectively, are Eq. 15 (0.9795), Eq. 16 (0.9878), Eq. 17 (0.9960) for Kalth and Eq. 18 (0.9960), Eq. 19 (0.9961), Eq. 20 (0.9966) for 30° 30′ N–33° 6′ N. Mean bias error (MBE) statistical method data, respectively, are Eq. 15 (0.0005), Eq. 16 (− 0.0061), Eq. 17 (− 0.0113) for Kalth and Eq. 18 (− 0.0113), Eq. 19 (0.0380), Eq. 20 (−0.2081) for 30° 30′ N–33° 6′ N. Root-mean-square error (RMSE) statistical method, respectively, is Eq. 17 (1.3631), Eq. 16 (2.3582), Eq. 15 (3.0574) for Kalth and Eq. 18 (0.0420), Eq. 19 (0.0566), Eq. 20 (0.2122) for 30° 30′ N–33° 6′ N. The t-sat (t-statistics), respectively, are Eq. 15 (0.0005), Eq. 16 (− 0.0061), Eq. 17 (− 0.0113) for Kalth and Eq. 18 (− 0.0113), Eq. 19 (0.0380), Eq. 20 (−0.2081) for 30° 30′ N–33° 6′ N.

| Equation | Kalth (30° 30′ N–33° 6′ N) | 30.50° N–33.10° N |
|----------|-----------------------------|-------------------|
| $R^2$    | 0.9795                      | 0.960             |
| MBE      | 0.0005                      | − 0.0061          |
| RMSE     | 3.0574                      | 2.3582            |
| t-stat   | 0.0005                      | 0.0086            |

### Table 7

| Equation | Kalth (30° 30′ N–33° 6′ N) | 30.50° N–33.10° N |
|----------|-----------------------------|-------------------|
| $R^2$    | 0.9795                      | 0.960             |
| MBE      | 0.0005                      | − 0.0061          |
| RMSE     | 3.0574                      | 2.3582            |
| t-stat   | 0.0005                      | 0.0086            |

### Equations

\[
\beta_{\text{opt, monthly}} = -0.0102(\delta)^2 - 1.2936(\delta) + 31.093 \quad (16)
\]

\[
\beta_{\text{opt, monthly}} = 0.0009(\delta)^3 - 0.0102(\delta)^2 - 1.6462(\delta) + 31.07 \quad (17)
\]

\[
\beta_{\text{opt, yearly}} = 0.9033(\phi) + 0.146 \quad (18)
\]

\[
\beta_{\text{opt, yearly}} = -0.0002(\phi)^2 + 0.913(\phi) \quad (19)
\]

\[
\beta_{\text{opt, yearly}} = -0.0008(\phi)^3 + 0.0511(\phi)^2 + 0.099(\phi) \quad (20)
\]

30° 30′ N–33° 6′ N. The statistical analysis indicates that the results from cubic correlation (Eq. 17) have comparatively less variation than linear and quadratic equations. Thereby, cubic relations for other sites have also been developed. The developed correlations for the selected sites and their corresponding statistical analysis are presented in Table 8. A comparison of the calculated values with the optimum angle equations is shown in Fig. 10a for Kalth and Fig. 10b for 30° 30′ N–33° 6′ N. Figure 10b advocates the precise estimation of yearly optimum tilt angle by Eq. 18 and Eq. 19, however, a comparatively large deviation of the results from Eq. 20. The reason for this deviation could be due to noisy estimates of higher-degree polynomial equations [45]. No such large deviations are observed for monthly optimum tilt angle estimating equations (Eqs. 15–17) from Fig. 10a. Therefore, the developed correlations are significantly effective both statistically and graphically for precise estimation of monthly and yearly optimum tilt angles.

Comparison for correlation models: present study, previous works, NASA and PVGIS

The comparison of the developed mathematical models with the previously developed correlations and solar datasets like NASA and PVGIS has been presented in this section. NASA data were obtained from the NASA Langley Research Center (LaRC) POWER Project, funded through the NASA Earth Science /Applied Science Program [36]. PVGIS data have
been developed for more than 10 years at the European Commission Joint Research Center at the JRC facility in Ispra, Italy [46]. The comparison is presented in Table 9. Tilt angle (β) values give rational results when the comparison data of different methods are examined. The comparison of previously developed models from the literature [47–50], solar datasets (NASA, PVGIS) and the present study signify that the optimum tilt angle suggested by developed models is significantly different from the other studies and effective as well. Thereby, the utilization of developed models will facilitate more benefit over the previously developed correlations and solar datasets.

### Conclusions

The current article discusses the monthly and yearly optimum tilt angle assessment for solar plant setup-able sites in the Western Himalayas region. Experimental validation of the estimated optimum tilt angles has been conducted, and correlations have been developed. Following broad conclusions can be drawn from this study.

1. The monthly optimum tilt angle varies from 0º to 56º throughout the year for selected sites. The minimum and maximum values of monthly optimum angle have been observed for May–July and December, respectively.

2. Annual average percentage performance enhancement (AAPPE) for solar collector tilted at monthly optimum tilt angle is 10–11%, 5–7% and 4–6% from solar collector fitted at horizontal, equal to latitude angle and yearly optimum tilt angle, respectively. Results depict that the optimum tilt angle significantly improves the solar radiation collection rate.

3. Validation of results has been conducted through experimental analysis. Power output performance enhancement (POPE) for PV panel tilted at monthly optimum tilt angle from horizontal, tilted at the latitude and yearly optimum tilt angle has been calculated. The percentage variation of POPE from the performance enhancement (PE) for one of the selected locations is found to be 8.84, 14.09 and 9.13 for \( \beta = 0^\circ, \beta = \beta_{\text{opt}}, \) yearly and \( \beta = \phi, \) respectively.

4. Correlation development (linear, quadratic and cubic polynomial equations) for the selected region based on latitude \( (30^\circ 30^\prime \text{N} - 33^\circ 6^\prime \text{N}) \) and declination angles (for \( \phi = 30^\circ 51^\prime 1.656^\prime \text{N} \)) has been conducted. The statistical analyses indicate that developed mathematical models are significantly applicable in the Western Himalayas region.

5. The applicability of the developed mathematical models has been checked by the comparison of results from
previously developed correlations and solar datasets (NASA and PVGIS). The intimacy of the current study results with the previously developed correlations, and solar datasets signifies the accuracy and applicability of the developed models for selected sites.

This study demonstrates the significance of optimum tilt angle assessment, their experimental validation and correlation development. This study would be useful for setting up a solar power plant at any suggested location.
