Immunopharmacological Studies on TBX, a New Antiallergic Drug
(3) Inhibitory Effects on Histamine Release from Lung Fragments
and Bronchoconstriction in Guinea Pigs

Abstract—The effects of 9-methyl-3-(1H-tetrazol-5-yl)-4H-pyrido[1,2-a]pyrimidin-4-one potassium salt (TBX), a new antiallergic drug, on histamine release from lung fragments, experimental asthma and isolated tracheal muscle were investigated in guinea pigs. TBX (10^{-7} to 10^{-4} g/ml) dose-dependently inhibited antigen-induced histamine release from lung fragments of guinea pigs passively sensitized with homologous IgE serum. Antigen inhalation-induced experimental asthma in passively sensitized animals was inhibited in a dose-dependent fashion by i.v. (1 to 5 mg/kg) and p.o. (10 to 100 mg/kg) administrations of TBX. In vivo bronchoconstriction by platelet-activating factor (PAF, i.v.) was also inhibited by TBX (0.3 to 10 mg/kg, i.v.). However, high concentrations of TBX (more than 3×10^{-4} g/ml) were needed to inhibit PAF-induced platelet aggregation in vitro. With regard to the effect on isolated tracheal muscle, TBX itself at concentrations higher than 10^{-5} g/ml induced dose-dependent reduction in the resting tonus, which was not affected by pretreatment with propranolol. Neither the leukotriene D4-induced contraction nor the prostaglandin F2\alpha-induced one was specifically antagonized by TBX. The results obtained indicate that TBX is an antiasthmatic agent effective in inhibiting both IgE- and PAF-induced bronchoconstriction, possibly by interfering with mediator release.

In the previous papers, 9-methyl-3-(1H-tetrazol-5-yl)-4H-pyrido[1,2-a]pyrimidin-4-one potassium salt (TBX) that shows no antagonistic actions on chemical mediators such as histamine and serotonin has been reported to be a new antiallergic drug capable of inhibiting both passive cutaneous anaphylaxis (PCA) and histamine release from mast cells in rodent models (1, 2). The potency of TBX to inhibit anaphylactic histamine release has also been shown to be much higher than that of disodium cromoglycate (DSCG) or tranilast. In addition, the antiallergic properties of TBX have been suggested to be different from those of DSCG and tranilast; for example, this agent was indeed effective in inhibiting homologous PCA in guinea pigs, known to be animals fairly insensitive to DSCG treatment.

On the other hand, numerous mediators, such as histamine and arachidonate metabolites, responsible for the airway constriction, have been implicated in the pathogenesis of allergic asthma. With regard to the arachidonate metabolites, particularly the slow reacting substance of anaphylaxis (SRS-A), TBX has been found to inhibit SRS-A release from human lung (3).

The above findings prompted us to examine the inhibitory activity of TBX on experimental asthma in animals. The main purpose of this paper is to study the antiasthmatic action of TBX in guinea pigs. The effect on in vivo bronchoconstriction induced
by platelet-activating factor (PAF) was also investigated.

Materials and Methods

Animals: Male Hartley guinea pigs weighing 300 to 450 g were obtained from Shizuoka Laboratory Animal Center.

Chemicals: The chemicals used were TBX (Tokyo Tanabe), DSCG (Fujisawa), tranilast (Kissei), pyrilamine maleate (Sigma), propranolol hydrochloride (Sumitomo), isoprotenerol bitartrate (Sigma), papaverine (Wako), theophylline (Wako), PAF (1-O-alkyl-2-acetyl-sn-glyceryl-3-phosphorylcholine, Sigma), prostaglandin F\textsubscript{2}{\alpha} (PGF\textsubscript{2}{\alpha}, Sigma), prostaglandin E\textsubscript{1} (PGE\textsubscript{1}, Sigma) and leukotriene D\textsubscript{4} (LTD\textsubscript{4}, Paesel GmbH & Co.). PAF, PGF\textsubscript{2}{\alpha} and LTD\textsubscript{4} were dissolved in chloroform, ethanol and methanol, respectively. They were diluted in physiological saline or Tyrode's solution before use. Other chemicals were dissolved in physiological saline or Tyrode's solution.

Antigen-induced histamine release from lung fragments: Guinea pigs were passively sensitized with i.v. injection of 1 ml of homologous anti-DNP IgE serum (1:1024 of 8 day homologous PCA titer) which had been prepared as previously described (1). After passive sensitization for 48 hr, they were bled and lung specimens were isolated. Lung fragments were prepared with a tissue sectioner (TC-2 Sorvall) and washed thoroughly with Tyrode's solution. The lung fragments (200 mg) were suspended in 1.6 ml of Tyrode's solution containing 20 mM HEPES buffer, preincubated for 15 min at 37°C, challenged with DNP-conjugated bovine serum albumin (DNP-BSA) at a final concentration of 1 mg/ml, and further incubated for 30 min. Histamine concentration in the supernatant was determined by the enzymatic radioassay (4). The total content of histamine was also assayed in the intact tissue which had been boiled for 10 min.

Experimental asthma induced by antigen inhalation: Guinea pigs were passively sensitized with i.v. injection of 1 ml/kg of homologous anti-DNP IgE serum. After 48 hr, they were placed in a body plethysmograph and challenged by inhalation of DNP-BSA without anesthesia and restraint. Aerosolization was performed by a nebulizer filled with 10 mg/ml of DNP-BSA solution at a flow rate of 5 l/min for 15 sec. Tidal volume was measured in conscious animals by transmitting changes in the body plethysmograph pressure to a differential pressure transducer (PDL-40GB, Kyowa Dengyo) as previously described (5) and recorded on a polygraph (polygraph 142-8, Sanei Sokki). A schematic diagram for the measurement of tidal volume

Fig. 1. Schematic diagram for the measurement of tidal volume in conscious guinea pigs passively sensitized with homologous anti-DNP IgE serum.
Inhibition of Bronchoconstriction by TBX

is shown in Fig. 1.

Relaxant and contractile responses of isolated tracheal muscle: Tracheal strip chains of normal guinea pigs were prepared according to the method of Takagi and Takayanagi (6). The preparations were suspended in an organ bath (37°C) containing 5 ml of Tyrode’s solution, which was gassed with a mixture of 95% O₂ and 5% CO₂, under a load of 1 g. Relaxant and contractile responses were measured using a isotonic transducer (TD-112S, Nihon Kohden) and displayed on a recorder (WT-685G, Nihon Kohden). With regard to chemical mediator-induced contraction of isolated tracheal muscle, both LTD₄ (10⁻⁹ g/ml) and PGE₂ (3x10⁻⁷ g/ml) were used as contractile agents.

Bronchoconstriction induced by PAF: Guinea pigs were anesthetized with i.p. injection of urethane (1.5 g/kg), trachea was cannulated for the measurement of bronchoconstriction, and spontaneous breathing was fully arrested with gallamine triethiodide (1 mg/kg, i.v.). Animals were then ventilated with a small animal respirator (Ugo Basile) at the rate of 70 breaths/min (5 to 8 ml of stroke volume). Airflow was measured with a bronchospasm transducer (Ugo Basile) connected to a side arm of the tracheal cannula and expressed as a percentage of maximum bronchoconstriction obtained by clamping off the trachea. PAF in a dose of 0.3 μg/kg was injected into the jugular vein in order to induce bronchoconstriction in vivo.

PAF-induced platelet aggregation: Blood was collected from the abdominal aorta of normal guinea pigs after light anesthesia with ether, and whole blood was mixed with 3.8% sodium citrate solution at the ratio of 9 to 1. The blood was centrifuged at 190xg for 10 min, and the top platelet-rich plasma (PRP) was carefully removed. The erythrocyte pellet was further centrifuged at 1,500xg for 10 min, and the supernatant (platelet poor plasma: PPP) was obtained. Platelets in the PRP were adjusted to a concentration of 450,000/μl using PPP. Ten microliters of PAF solution (final concentration of 5x10⁻⁶ g/ml) was added to 250 μl of PRP, and platelet aggregation was monitored by measuring changes in turbidity with a 6-channel aggregometer, model RMA61 (Rikadenki) at 37°C. Platelet aggregation was expressed in terms of percent change; it was calculated from the maximum transmittance change by assigning the transmittance of unstimulated PPP to be 0% and that of PPP to be 100%.

Statistical analysis: Results were expressed as the mean±S.E. Statistical significance was determined by Student’s t-test. ED₅₀ was obtained by the logit method.

Results

Effect on antigen-induced histamine release from lung fragments of guinea pigs: The fragments were preincubated with the drugs for 15 min before antigen challenge. As shown in Fig. 2, TBX at concentrations of 10⁻⁷ to 10⁻⁴ g/ml dose-dependently inhibited antigen-induced histamine release from lung fragments of guinea pigs passively sensitized with homologous anti-DNP IgE serum. Similarly, tranilast dose-dependently inhibited histamine release. In contrast, DSCG exerted a weak inhibitory influence on histamine release. Note that the inhibitory action of TBX at concentrations of 10⁻⁷ to 10⁻⁵ g/ml upon histamine release was superior to that of...
tranilast.

**Effect on experimental asthma by antigen inhalation:** A typical example of experimental asthma induced by antigen inhalation in a conscious guinea pig passively sensitized with homologous anti-DNP IgE serum is shown in Fig. 3A. Antigen inhalation resulted in a rapid decrease in tidal volume together with disorder of respiration; the lowest tidal volume (about 50%) and the highest increase in respiratory rate were observed at 2 to 3 min after antigen inhalation, and they were gradually restored as time passed. In contrast, Fig. 3B shows one example of strong inhibition of experimental asthma by 5 mg/kg of TBX, which was intravenously administered 3 min before antigen inhalation. The results pertaining to the i.v. administration of TBX, DSCG and pyrilamine at 3 min prior to antigen challenge are summarized in Fig. 4. TBX (1 to 5 mg/kg, i.v.) dose-dependently inhibited antigen inhalation-induced experimental asthma as shown in Fig. 4A; the i.v. administration of 2.5 to 5 mg/kg of the drug induced the significant inhibition of experimental asthma at the early phase of the decreases in tidal volume. Similar results were obtained with pyrilamine (0.1 mg/kg, i.v.) (Fig. 4B), but DSCG (25 mg/kg, i.v.) did not inhibit this experimental asthma. Oral administration of TBX in doses of 10 to 100 mg/kg administered either 2 or 8 hr before antigen inhalation also showed the dose-dependent inhibition of experimental asthma (Fig. 5). Note that TBX, which was administered orally 8 hr before antigen challenge, was still active in the inhibition of experimental asthma (Fig. 5B), suggesting that this drug is long-acting in guinea pigs.

**Relaxant effect on isolated tracheal muscle of guinea pigs:** As illustrated in Fig. 6, TBX at high concentrations of $10^{-6}$ to $10^{-3}$ g/ml induced the dose-dependent reduction in the resting tonus of the tracheal strip chains of guinea pigs.

*Fig. 3.* Experimental asthma induced by antigen inhalation in a control guinea pig (A) and its inhibition by i.v. administration of 5 mg/kg of TBX (B). Animals were passively sensitized with homologous anti-DNP IgE serum. Either physiological saline or TBX was administered i.v. 3 min before antigen inhalation (DNP-BSA).
Inhibition of Bronchoconstriction by TBX

Fig. 4. Effect of TBX (A), DSCG and pyrilamine (B) on antigen inhalation-induced experimental asthma in conscious guinea pigs passively sensitized with homologous anti-DNP IgE serum. Drugs were given i.v. 3 min before antigen challenge. Each point represents the mean±S.E. of 8 animals. In general, the S.E. of each point was within 15% of the mean. *, **: Statistically significant difference from the control at P<0.05 and P<0.01, respectively.

guinea pigs. However, isoproterenol, papaverine and theophylline (less than 10^-5 g/ml) showed stronger reduction in the resting tonus than did TBX. The relaxant potency of TBX was compared with that of theophylline, papaverine or isoproterenol; EC50 values of all these drugs were 8.2×10^-5 g/ml for TBX, 1.2×10^-6 g/ml for theophylline, 2.1×10^-7 g/ml for papaverine and 7.1×10^-10 g/ml for isoproterenol, respectively. Further experiments were carried out to study whether TBX-induced reduction in the resting tonus was affected by pretreatment with propranolol (10^-6 g/ml). One example is shown in Fig. 7. Propranolol pretreatment resulted in no abrogation of TBX-induced reduction in the resting tonus. Note that isoproterenol-induced reduction was completely blocked by such pretreatment.

Effect on LTD4 or PGF2α-induced contraction of isolated tracheal muscle of guinea pigs: The tracheal strip chains were pretreated for 5 min with TBX at a concentration of 10^-5 g/ml, which produced little relaxant effect on the resting tonus, and LTD4 or PGF2α was then added. TBX inhibited neither LTD4-induced contraction (100 versus 92.8±1.6 in terms of percent change, n=3) nor PGF2α-induced contraction (100 versus 98.7±5.2%, n=3).

Effect on PAF-induced bronchoconstriction in guinea pigs: As indicated in Table 1, TBX (0.3 to 10 mg/kg, i.v.), administered 2 min before PAF injection, dose-dependently inhibited PAF-induced bronchoconstriction, and significant inhibition was obtained with this drug (1 to 10 mg/kg, i.v.). In contrast, DSCG (10 mg/kg, i.v.) was ineffective for inhibiting PAF-induced bronchoconstriction.

Effect on PAF-induced platelet aggregation in guinea pigs: A typical example is shown in Fig. 8, and the results are summarized in Table 2. PAF-induced platelet aggregation was dose-dependently inhibited by TBX (3×10^-4 to 3×10^-3 g/ml) as well as by PGE1 (3×10^-8 to 3×10^-7 g/ml), one of the anti-aggregating

PGs. Note that much higher concentrations of TBX than those of PGE1 were needed to induce such inhibition.

Discussion

The present results, in agreement with
Inhibition of Bronchoconstriction by TBX

Fig. 7. Effect of pretreatment with propranolol (Prop, 10^-6 g/ml) on TBX (3×10^-4 g/ml) or isoproterenol (Isp, 3×10^-9 g/ml)-induced reduction of the resting tonus of guinea pig tracheal strip chains.

Table 1. Effect of TBX and DSCG on PAF-induced bronchoconstriction in guinea pigs

| Drug    | Dose (mg/kg) | % Increase in respiratory overflow |
|---------|--------------|-----------------------------------|
| Control | —            | 74.3±4.4                          |
| TBX     | 0.3          | 56.6±15.8                         |
|         | 1            | 26.9±11.7**                       |
|         | 10           | 15.0±5.5**                        |
|         | 10           | 76.3±13.5                         |
| DSCG    | 25 mg/kg, i.v. | 87.6±12.3                         |

Drugs were given i.v. 2 min before PAF (0.3 μg/kg) injection. Each value represents the mean±S.E. of 5 to 10 animals. **: Statistically significant difference from the control at P<0.01.

previous observations (1, 2), indicate that TBX is a potent inhibitor of IgE-mediated histamine release from guinea pig lung. The prophylactic effects of TBX on antigen inhalation-induced experimental asthma were further studied using body plethysmography in conscious guinea pigs passively sensitized with homologous IgE serum. As expected, TBX (1 to 5 mg/kg, i.v. and 10 to 100 mg/kg, p.o.) dose-dependently inhibited the decrease in tidal volume caused by antigen inhalation. Interestingly, TBX was still active in the inhibition of experimental asthma even when administered p.o. 8 hr prior to the challenge, suggesting that this drug is long-acting in guinea pigs. No significant inhibition of this experimental asthma, however, was seen in animals treated with DSCG (25 mg/kg, i.v.), as already confirmed by many investigators (7-10), demonstrating that DSCG had little or no ability to inhibit guinea pig models. It should be emphasized that treatment with pyrilamine, one of the potent antihistamines, resulted in no complete abrogation of experimental asthma, suggesting that other mediators except for histamine are also responsible for the airway constriction. For example, both lipoxygenase and cyclooxygenase products of arachidonate are also considered to be potent constrictors of airways (11-16). In particular, LTC4, LTD4 and LTE4, known to comprise SRS-A (17) and to be products of the lipoxygenase pathway, have been shown to be more potent than histamine in causing contraction of both central and peripheral airways in animals and humans (18-20). Although the inhibitory effect of TBX on SRS-A release from guinea pig lung was not investigated in the present study, this agent has been reported to inhibit IgE-mediated SRS-A release from human lung (3). Thus, it is suggested that the inhibition of not only histamine release but also SRS-A release may be responsible for the antias-
Fig. 8. Inhibitory effect of TBX and PGE₁ on PAF-induced platelet aggregation in guinea pigs.

Table 2. Inhibitory effect of TBX and PGE₁ on PAF-induced platelet aggregation in guinea pigs

| Drug  | Concentration (g/ml) | % Inhibition |
|-------|----------------------|--------------|
| TBX   | 10⁻⁴                 | 2.4±1.4      |
|       | 3×10⁻⁴              | 15.6±7.5     |
|       | 10⁻³                | 73.3±9.6     |
|       | 3×10⁻³              | 100          |
|       | 10⁻⁸                | 0.1±1.7      |
|       | 3×10⁻⁸              | 9.7±4.9      |
|       | 10⁻⁷                | 78.4±10.2    |
|       | 3×10⁻⁷              | 93.3±5.4     |

Each value represents the mean±S.E. of 3 to 5 experiments.

With regard to antagonistic actions on synthetic lipooxygenase and cyclooxygenase products, neither LTD₄- nor PGF₂α-induced bronchoconstriction of guinea pig trachea in vitro was affected by 10⁻⁵ g/ml of TBX, which exerted little influence on the resting

thmatic activity of TBX in guinea pigs. On the other hand, cyclooxygenase products of arachidone metabolism such as PGD₂ and PGF₂α have also been demonstrated to play an important role in the airway constriction (21, 22). However, it is unknown at present whether TBX inhibits the generation of cyclooxygenase products in guinea pig lung during IgE-mediated hypersensitivity reac-
Inhibition of bronchoconstriction by TBX

The results that TBX displayed no inhibition of bronchoconstriction caused by LTD₄ and PGF₂α are consistent with the previous findings demonstrating that no inhibition of rat skin reactions induced by histamine, serotonin and bradykinin was obtained with TBX (1). These observations strongly suggest that the antiasmatic activity of TBX in guinea pigs is not due to antagonistic actions on histamine and arachidonate metabolites responsible for bronchoconstriction. Nevertheless, it ought to be mentioned that TBX itself at concentrations higher than 10⁻⁵ g/ml induced the dose-dependent reduction in the resting tonus of isolated guinea pig trachea muscle. In addition, TBX-induced reduction in the resting tonus was not affected by pretreatment with propranolol, thus suggesting that such reduction is not mediated by a β-adrenergic mechanism. This suggestion is further supported by our previous findings that propranolol treatment did not modify TBX's inhibition of rat homologous PCA (1). TBX has been found to have an inhibitory activity on cyclic AMP-dependent phosphodiesterase derived from lung (2); this may be one of the mechanisms by which TBX induces a reduction in the resting tonus of guinea pig tracheal muscle.

Most interesting are the observations that TBX inhibits in vivo bronchoconstriction induced by PAF, known to be one of the important mediators of immediate hypersensitivity (23-26). Indeed, TBX (0.3 to 10 mg/kg, i.v.), but not DSCG (10 mg/kg, i.v.), displayed the dose-dependent inhibition of PAF-induced bronchoconstriction in guinea pigs. Such inhibition, however, does not seem to be based on the direct antagonistic action on PAF, since high concentrations of TBX (more than 3×10⁻⁴ g/ml) were required to inhibit PAF-induced platelet aggregation in vitro. Although in vivo bronchoconstriction by PAF has been reported to be fully platelet-dependent (25, 27, 28), little is known about this bronchoconstriction mechanism. A few candidates have been consequently suggested by several investigators as mediators of PAF-induced bronchoconstriction (24, 25, 29). For example, ADP, arachidonate metabolites and Ca²⁺, which are released from stimulated platelets or other cells, have been shown to be indirectly involved in PAF-induced bronchoconstriction in vivo. Especially, lipoxygenase but not cyclooxygenase products of arachidonate are now considered to play a key role in the bronchoconstricting effect of PAF, because lipoxygenase inhibitors, LT antagonists and LT synthesis inhibitors are known to be effective in inhibiting PAF-induced bronchoconstriction (24, 25). Therefore, more detailed experiments are needed to investigate the mechanism by which TBX inhibits PAF-induced bronchoconstriction.
