GONALITY OF MODULAR CURVES IN CHARACTERISTIC \( p \)

BJORN POONEN

ABSTRACT. Let \( k \) be an algebraically closed field of characteristic \( p \). Let \( X(p^e; N) \) be the curve parameterizing elliptic curves with full level \( N \) structure (where \( p \nmid N \)) and full level \( p^e \) Igusa structure. By modular curve, we mean a quotient of any \( X(p^e; N) \) by any subgroup of \((\mathbb{Z}/p^e\mathbb{Z})^r \times \text{SL}_2(\mathbb{Z}/N\mathbb{Z}))/\{\pm 1\}\). We prove that in any sequence of distinct modular curves over \( k \), the \( k \)-gonality tends to infinity. This extends earlier work, in which the result was proved for particular sequences of modular curves, such as \( X_0(N) \) for \( p \nmid N \). We give an application to the function field analogue of a uniform boundedness statement for the image of Galois on torsion of elliptic curves.

1. Introduction

1.1. Gonality. The gonality \( \gamma_k(X) \) of a curve\(^1\) \( X \) over a field \( k \) is the smallest possible degree of a dominant rational map \( X \dasharrow \mathbb{P}^1_k \). For any field extension \( L \) of \( k \), we define also the \( L \)-gonality \( \gamma_L(X) \) of \( X \) as the gonality of the base extension \( X_L := X \times_k L \). It is an invariant of the function field \( L(X) \) of \( X_L \).

1.2. General facts about gonality. The following facts are well-known.

Proposition 1.1. Let \( X \) be a curve of genus \( g \) over a field \( k \).

(i) If \( L \) is a field extension of \( k \), then \( \gamma_L(X) \leq \gamma_k(X) \).

(ii) If \( k \) is algebraically closed, and \( L \) is a field extension of \( k \), then \( \gamma_L(X) = \gamma_k(X) \).

(iii) If \( g > 1 \), then \( \gamma_k(X) \leq 2g - 2 \). For each \( g > 1 \), there exist \( k \) and \( X \) for which equality holds.

(iv) If \( X(k) \neq \emptyset \), then \( \gamma_k(X) \leq g + 1 \). If \( X(k) \neq \emptyset \) and \( g \geq 2 \), then \( \gamma_k(X) \leq g \).

(v) If \( k \) is algebraically closed, then \( \gamma_k(X) \leq \left\lfloor \frac{2g + 3}{2} \right\rfloor \). Equality holds for a general curve of genus \( g \) over \( k \).

(vi) If \( \pi: X \dasharrow Y \) is a dominant rational map of curves over \( k \), then \( \gamma_k(X) \leq (\text{deg} \pi)\gamma_k(Y) \).

(vii) If \( \pi: X \dasharrow Y \) is a dominant rational map of curves over \( k \), then \( \gamma_k(Y) \leq \gamma_k(X) \).

Proof.

(i) Trivial.

(ii) Given a map over \( L \), standard specialization arguments give a map over \( k \) of the same degree.

---

\(^1\)All our curves are assumed to be geometrically integral.
(iii) The canonical linear system $|K|$ has dimension $g - 1 \geq 1$ and degree $2g - 2$. So we may use a rational function whose divisor is the difference of two different canonical divisors. Equality holds for the general curve over the function field of the moduli space of genus-$g$ curves in characteristic 0, since its only line sheaves are the powers of the canonical sheaf: this was the Franchetta conjecture, proved in [Harer1983] and strengthened in [Mestrano1987].

(iv) Let $P \in X(k)$. The Riemann-Roch theorem shows that $\dim |(g + 1)P| \geq 1$, and that $\dim |K - (g - 2)P| \geq 1$ if $g - 2 \geq 0$. These linear systems have degree $g + 1$ and $g$, respectively.

(v) These are consequences of Brill-Noether theory: see (1.1) and (1.5) of [Arbarello-et-al1985] Chapter V for an exposition. The first statement is proved in arbitrary characteristic in [Kleiman-Laksov1972] and [Kleiman-Laksov1974]. The second statement is proved in characteristic 0 in [Farkas1966] Martens1967 Martens1968, and can be deduced in characteristic $p$ from the unramified case of Osserman2005 Theorem 1.2, for instance.

(vi) Trivial.

(vii) (The ideas in the following argument go back at least to Newman1972 Theorem VII.2.) Choose $f \in k(X)$ of degree $d := \gamma_k(X)$. Let $r = \deg \pi = [k(X) : k(Y)]$. Let $P(T) \in k(Y)[T]$ be the characteristic polynomial of $f$ viewed as an element of the field extension $k(X)$ of $k(Y)$. For some finite normal extension $M$ of $k(Y)$, we may write $P(T) = \prod_{i=1}^r (T - f_i)$ for some $f_i \in M$. As a function in $M$, $f$ has degree $[M : k(Y)]d$. The same is true of each $f_i$, since they are all in the same Aut($M/k(Y)$)-orbit. The polar divisor of a coefficient of $P$ viewed in $M$ is at most the sum of the polar divisors of the $f_i$, so each coefficient has degree at least $r[M : k(X)]d = [M : k(Y)]d$ as a function in $M$, and hence degree at most $d$ as a function in $k(Y)$. Since $f$ is non-constant, at least one of these coefficients is non-constant. Thus $\gamma_k(Y) \leq d$.

\[ \square \]

### 1.3. Modular curves.

Our goal is to obtain lower bounds on the gonality of modular curves. By Proposition 1.1(ii), it suffices to consider $k = \mathbb{C}$ and $k = \mathbb{F}_p$ (an algebraic closure of $\mathbb{F}_p$) for each prime $p$.

Suppose $N$ is a positive integer not divisible by the characteristic of $k$. Choose a primitive $N$-th root of unity $\zeta$. Let $X(N)$ be the smooth projective model of the (possibly coarse) moduli space parameterizing triples $(E, P, Q)$ where $P, Q \in E$ are a basis for $E[N]$ with Weil pairing $e_N(P, Q) = \zeta$. For $k = \mathbb{C}$, we can describe $X(N)(\mathbb{C})$ alternatively as the quotient of an extended upper half plane by a finite-index subgroup of $\text{PSL}_2(\mathbb{Z})$. More generally, any congruence subgroup $G \leq \text{PSL}_2(\mathbb{Z})$ gives rise to a curve $X_G$ over $\mathbb{C}$. We have the following theorem of Abramovich:

**Theorem 1.2** ([Abramovich1998]). Let $D = (\text{PSL}_2(\mathbb{Z}) : G)$. Then $\gamma_{\mathbb{C}}(X_G) \geq \frac{7}{800}D$.

**Remark 1.3.** As mentioned in [Abramovich1998], combining Theorem 1.2 with the genus bound $g - 1 \leq D/12$ [Shimura1994 Proposition 1.40] yields

$$\gamma_{\mathbb{C}}(X_G) \geq \frac{21}{200}(g - 1).$$
The proof of Theorem 1.2 makes use of a lower bound on the leading nontrivial eigenvalue of the noneuclidean Laplacian; this bound has been improved since 1996, so the constants $7/800$ and $21/200$ can be improved too. See also [Baker-et-al2005, §4.3] for some further results.

In characteristic $p$, one has other kinds of modular curves, involving level structure where $p$ divides the level. If $q = p^f$ for some $e \in \mathbb{Z}_{>1}$, the **Igusa curve of level** $q$ is the smooth projective model $\text{Ig}(q)$ of the curve over $\mathbb{F}_p$ parameterizing pairs $(E, R)$ where $E$ is an ordinary elliptic curve, and $R$ is a generator of the kernel of the degree-$q$ Verschiebung isogeny $V_q: E(q) \rightarrow E$, where $E(q)$ is the elliptic curve obtained by raising all the coefficients of a model of $E$ to the $q$-th power. Given $N$ not divisible by $p$, and $q = p^f$, we can define also a hybrid modular curve $X(p^f; N)$ over $\mathbb{F}_p$ parameterizing $(E, R, P, Q)$, with $R \in \ker V_q$ and $P, Q \in E[N]$ as above.

The group $G_{p^f N} := (\mathbb{Z}/p^f \mathbb{Z})^\times \times \text{SL}_2(\mathbb{Z}/N \mathbb{Z})$ acts on $X(p^f; N)$. The kernel of the action is $\{\pm 1\}$ embedded diagonally in $G_{p^f N}$. For any subgroup $G \leq G_{p^f N}$ containing $\{\pm 1\}$, let $X_G$ be the smooth projective model of the quotient $X(p^f; N)/G$. The $G_{p^f N}$ form an inverse system with inverse limit

$$S := \mathbb{Z}_p^\times \times \prod_{\text{prime } \ell \neq p} \text{SL}_2(\mathbb{Z}_\ell).$$

The inverse image of $G$ under $S \rightarrow G_{p^f N}$ is an open subgroup of the profinite group $S$, and every open subgroup of $S$ containing $\{\pm 1\}$ arises this way for some $p^f N$. Thus we may define $X_G$ for any open subgroup $G$ of $S$ containing $\{\pm 1\}$.

It seems likely that there is a constant $c > 0$ independent of $p$ and $G$ such that $\gamma_{p^f N}(X_G) \geq c(S : G)$. We are unable to prove such a linear lower bound, even for fixed $p$, but we can show that the gonality goes to infinity for fixed $p$. Here is our main theorem:

**Theorem 1.4.** Fix a prime $p$. Let $G_1, G_2, \ldots$ be a sequence of distinct open subgroups of $S$ containing $\{\pm 1\}$. Then $\gamma_{p^f N}(X_{G_i}) \rightarrow \infty$ as $i \rightarrow \infty$.

1.4. Outline of proof of main theorem. Many of the ideas used in the proof of Theorem 1.4 are due to earlier authors, though we consider a broader class of modular curves than had been treated earlier. Section 2 proves Theorem 1.2 an inequality in the direction opposite to Proposition 1.1(i): the ideas used here and their application to the classical modular curves $X_0(N)$ can be found in [Harris-Silverman1991], [Nguyen-Saito1996preprint], and [Baker-thesis, Chapter 3]. Theorem 2.5 reduces the problem to finding lower bounds on gonality over finite fields, and these can be obtained by counting in the spirit of [Ogg1974], which among other things determined the $N$ for which $X_0(N)$ is hyperelliptic. In Section 3 we find that, as in [Ogg1974], modular curves of level prime to $p$ have too many super-singular points over $\mathbb{F}_p$ to have small gonality. In Section 4 we cite results of Schweizer [Schweizer2005], who obtained lower bounds on the $\mathbb{F}_p$-gonality of Igusa curves directly from the geometry of the curves, instead of first getting lower bounds on $\mathbb{F}_p$-gonality by counting $\mathbb{F}_p$-points. Section 5 uses Goursat’s lemma to study the subgroups of $S$, so that the prime-to-$p$ and $p$-power cases can be combined to prove the general case of Theorem 1.4 in Section 6.

1.5. Application to the image of Galois. One application of results like Theorem 1.4, noted already by many other authors, is to the function field analogue of the strong uniform
boundedness theorem for elliptic curves. By the work of Mazur, Kamienny, and Merel [Merel1996], for every \( d \in \mathbb{Z}_{\geq 1} \), there exists a constant \( N_d \) such that for any number field \( K \) with \( [K : \mathbb{Q}] \leq d \) and for any elliptic curve \( E \) over \( K \), the torsion subgroup \( E(K)_{\text{tors}} \) of the finitely generated abelian group \( E(K) \) satisfies \#\( E(K)_{\text{tors}} \leq N_d \). In the function field case, we can prove a stronger result, one which bounds the index of the image of Galois acting on \( \mathbb{Z}^s \), there exists a homomorphism
\[
\rho_E : \text{Gal}(K^s/K) \to \mathbb{Z}_p^s \times \prod_{\ell \neq p} \text{GL}_2(\mathbb{Z}_\ell)
\]
describing the Galois action on the Tate modules of \( E \). (Of course, if \( \text{char} K = 0 \), there is no \( \mathbb{Z}_p^s \) factor.)

**Theorem 1.5.** Given \( p \geq 0 \) and \( d \in \mathbb{Z}_{\geq 1} \), there exists a constant \( N_{p,d} \) such that for any field \( k \) of characteristic \( p \), any field \( K \) of degree \( \leq d \) over \( k(t) \), and any elliptic curve \( E \) over \( K \) with \( j(E) \) not algebraic over \( k \), the index \( (S : \rho_E(\text{Gal}(K^s/K)) \cap S) \) is at most \( N_{p,d} \).

**Remark 1.6.** In Theorem 1.5, we cannot hope to bound the index of \( \rho_E(\text{Gal}(K^s/K)) \) in \( \mathbb{Z}_p^s \times \prod_{\ell \neq p} \text{GL}_2(\mathbb{Z}_\ell) \) (i.e., with \( \text{GL}_2 \) instead of the \( \text{SL}_2 \) in the definition of \( S \)), since the determinant of the image in \( \text{GL}_2(\mathbb{Z}_\ell) \) gives the action of \( \text{Gal}(K^s/K) \) on roots of unity, and this is trivial if \( k \) is algebraically closed, for example.

Theorem 1.5 will be deduced from Theorem 1.4 in Section 7.

### 2. Change in gonality under extension of the ground field

In this section we give an exposition of the “tower theorem” [Nguyen-Saito1996preprint] of Nguyen and Saito [Nguyen-Saito1996preprint], and its implication for relating gonalities of a single curve over different fields. We will reprove it as our Proposition 2.4, since [Nguyen-Saito1996preprint] remains unpublished after 10 years, and since we can simplify the proof slightly. Throughout this section, \( k \) is a perfect field.

**Proposition 2.1** (Castelnuovo-Severi inequality). Let \( F, F_1, F_2 \) be function fields of curves over \( k \), of genera \( g, g_1, g_2 \), respectively. Suppose that \( F_i \subseteq F \) for \( i = 1, 2 \) and the compositum of \( F_1 \) and \( F_2 \) in \( F \) equals \( F \). Let \( d_i = [F : F_i] \) for \( i = 1, 2 \). Then
\[
g \leq d_1g_1 + d_2g_2 + (d_1 - 1)(d_2 - 1).
\]

**Proof.** See [Stichtenoth1993] III.10.3.]  

Let \( X \) be a curve over \( k \). A subfield \( F \) of \( k(X) \) will be called \( d \)-controlled if there exists \( e \in \mathbb{Z}_{>0} \) such that \( [k(X) : F] = d/e \) and the genus of \( F \) is \( \leq (e - 1)^2 \).

**Lemma 2.2.** If \( F \) is \( d \)-controlled, and \( f \in k(X) \) is a rational function of degree \( d \), then \( F(f) \) is \( d \)-controlled.

**Proof.** View \( F(f) \) as the compositum of \( F \) and \( k(f) \) in \( k(X) \). Let \( a = [F(f) : F] \). Then \( [k(X) : F(f)] = d/(ae) \), so \( [F(f) : k(f)] = ae \). By Proposition 2.1 the genus of \( F(f) \) is at most
\[
a(e - 1)^2 + 0 + (a - 1)(ae - 1) = (ae - 1)^2 - ae(a - 1)(e - 1) \leq (ae - 1)^2,
\]
since \( a, e \geq 1 \).
Corollary 2.3. A subfield of \( k(X) \) generated over \( k \) by one or more elements of degree \( d \) is \( d \)-controlled.

Proof. Induction on the number of elements: the case of one element is trivial \((e = 1)\), and Lemma 2.2 gives the inductive step. \(\square\)

Proposition 2.4 (Tower theorem). Let \( X \) be a curve over a perfect field \( k \). Let \( L \supseteq k \) be an algebraic field extension. Let \( d = \gamma_L(X) \). Then \( k(X) \) has a \( d \)-controlled subfield.

Proof. Enlarging \( L \) cannot increase \( \gamma_L(X) \), so we may assume \( L/k \) is Galois. Choose \( f \in L(X) \) of degree \( d \). Let \( F_L \) be the subfield generated over \( L \) by the \( \text{Gal}(L/k) \)-conjugates of \( f \).

By Corollary 2.3 \( F_L \) is \( d \)-controlled as a subfield of \( L(X) \). The action of \( \text{Gal}(L/k) \) on \( L(X) \) preserves \( F_L \), and the invariant subfield \( F_k := F_L^{\text{Gal}(L/k)} \) satisfies \([k(X) : F_k] = [L(X) : F_L]\) and has the same genus as \( F_L \). Thus \( F_k \) is a \( d \)-controlled subfield of \( k(X) \). \(\square\)

Theorem 2.5. Let \( X \) be a curve over a perfect field \( k \). Let \( L \supseteq k \) be an algebraic field extension. Let \( d = \gamma_L(X) \). Assume that \( X(k) \neq \emptyset \).

(i) If \( d \leq 2 \), then \( \gamma_k(X) = d \).
(ii) If \( d > 2 \), then \( \gamma_k(X) \leq (d - 1)^2 \).
(iii) In any case, \( \gamma_L(X) \geq \sqrt{\gamma_k(X)} \).

Proof.

(i) If \( d = 1 \), then \( X \simeq \mathbb{P}^1_k \), so \( \gamma_k(X) = 1 \). If \( d = 2 \), then \( X \) is elliptic or hyperelliptic; if elliptic, then \( \gamma_k(X) = 2 \); if hyperelliptic then the canonical map is a degree-2 map to a genus-0 curve \( Z \) over \( k \), and \( Z(k) \neq \emptyset \) so \( Z \simeq \mathbb{P}^1_k \), so \( \gamma_k(X) = 2 \).

(ii) Now suppose \( d > 2 \). By Proposition 2.4 there exists \( e \in \mathbb{Z}_{>0} \) and a rational map \( \pi : X \dashrightarrow Y \) of curves over \( k \) such that \( \deg \pi = d/e \) and the genus \( g \) of \( Y \) satisfies \( g \leq (e - 1)^2 \). We have \( Y(k) \neq \emptyset \). If \( g = 0 \), then \( Y \simeq \mathbb{P}^1 \), so

\[
\gamma_k(X) \leq d/e \leq d < (d - 1)^2.
\]

If \( g = 1 \), then \( e \geq 2 \) and \( \gamma_k(Y) = 2 \), so

\[
\gamma_k(X) \leq (d/e)\gamma_k(Y) \leq (d/2)2 = d < (d - 1)^2.
\]

If \( g \geq 2 \), then \( \gamma_k(Y) \leq g \) by Proposition 1.1 (iv), so

\[
\gamma_k(X) \leq \frac{d}{e}\gamma_k(Y) \leq \frac{d}{e}(e - 1)^2.
\]

For \( e \in [1, d] \), the function \( \frac{d}{e}(e - 1)^2 \) is maximized at \( e = d \), and the value there is \((d - 1)^2\).

(iii) This follows directly from the first two parts. \(\square\)

Remark 2.6. The hypothesis \( X(k) \neq \emptyset \) is necessary: Genus-1 curves over \( \mathbb{Q} \) have \( \mathbb{Q} \)-gonality 2, but their \( \mathbb{Q} \)-gonality can be arbitrarily large.

Remark 2.7. We do not know whether the \((d - 1)^2\) in Theorem 2.5 (ii) can be improved.

Remark 2.8. For \( N = 38, 44, 53, 61 \), the modular curve \( X_0(N) \) is of genus 4 and has \( \mathbb{Q} \)-gonality 4 and \( \mathbb{Q} \)-gonality 3 [Hasegawa-Shimura 1999, p. 136]. In particular, Theorem 2.5 (ii) is best possible for \( d = 3 \).
3. Level prime to $p$

Suppose $p \nmid N$. We begin by defining a twisted form $X(N)'$ over $\mathbb{F}_{p^2}$ of $X(N)$. Let $M$ be $(\mathbb{Z}/N\mathbb{Z})^2$ made into a $\text{Gal}(\mathbb{F}_p^2/\mathbb{F}_{p^2})$-module by letting the $p^2$-power Frobenius automorphism act as multiplication by $-p$. There exists an isomorphism of Galois modules $\iota: \Lambda^2 M \to \mu_N$; fix one. Let $X(N)'$ be the smooth projective model of the affine curve over $\mathbb{F}_{p^2}$ parameterizing pairs $(E, \phi)$ where $E$ is an elliptic curve and $\phi$ is an isomorphism $E[N] \to M$ under which the Weil pairing corresponds to $\iota$. Over $\mathbb{F}_p$, $X(N)'$ becomes isomorphic to $X(N)$. The automorphisms of $M$ as an abelian group automatically commute with the Galois action, so they induce automorphisms of $X(N)'$ defined over $\mathbb{F}_{p^2}$. Thus we get $\text{SL}_2(\mathbb{Z}/N\mathbb{Z})/\{\pm 1\} \leq \text{Aut}(X(N)')$. Moreover, it follows from [Baker-et-al2005, Lemma 3.21] that all the points of $X(N)'$ corresponding to supersingular elliptic curves are defined over $\mathbb{F}_{p^2}$.

**Proposition 3.1.** Let $p$, $N$, and $X(N)'$ be as above. Let $G$ be a subgroup of $\text{SL}_2(\mathbb{Z}/N\mathbb{Z})/\{\pm 1\}$ of index $D$. Let $X$ be the curve $X(N)'/G$. Then the $\mathbb{F}_{p^2}$-gonality $\gamma$ of $X$ satisfies

$$
\gamma \geq \frac{p - 1}{12(p^2 + 1)} D.
$$

**Proof.** This resembles the proof of [Baker-et-al2005, Lemma 3.22]. By [Baker-et-al2005, Lemma 3.20], the number of supersingular points on $X$ is $\geq (p - 1)D/12$, and these are images of supersingular points on $X(N)'$ so they are defined over $\mathbb{F}_{p^2}$; thus $\#X(\mathbb{F}_{p^2}) \geq (p - 1)D/12$. On the other hand, $\#X(\mathbb{F}_{p^2}) \leq \gamma \#\mathbb{P}^1(\mathbb{F}_{p^2}) = \gamma(p^2 + 1)$. Combine the two previous sentences. \qed

**Remark 3.2.** Let $g$ be the genus of $X$. One could also combine Proposition 3.1 with the bound $g - 1 < D/12$ of [Shimura1994] Proposition 1.40 to give a lower bound for $\gamma$ in terms of $g$ instead of $D$.

We now consider the $\mathbb{F}_p$-gonality of all modular curves of level prime to $p$.

**Corollary 3.3.** Fix $p$. Define $\Phi_p(D) := \sqrt{\frac{p - 1}{12(p^2 + 1)} D}$. If $G$ is the inverse image under $S \to \prod_{\ell \neq p} \text{SL}_2(\mathbb{Z}_\ell)$ of an open subgroup of index $D$ in $\prod_{\ell \neq p} \text{SL}_2(\mathbb{Z}_\ell)$ containing $\{\pm 1\}$, then $\gamma_{\mathbb{F}_p}(X_G) \geq \Phi_p(D)$.

**Proof.** Combine Proposition 3.1 and Theorem 2.25. \qed

**Remark 3.4.** One could also consider Atkin-Lehner quotients of $X_0(N)$ for $N$ prime to $p$. These are generally not of the form $X_G$. Nevertheless, gonality bounds tending to infinity for fixed $p$ can be obtained: first apply Proposition 3.1 to get a lower bound on $\gamma_{\mathbb{F}_p}(X_0(N))$, next use Proposition 1.1(vi) to get a lower bound on the $\mathbb{F}_p$-gonality of any quotient of $X_0(N)$, and finally apply Theorem 2.25. This works since the size of the Atkin-Lehner group (some power of 2) is asymptotically small compared to the index of the congruence subgroup $\Gamma_0(N)$ in $\text{PSL}_2(\mathbb{Z})$.

4. Level a power of $p$

The necessary lower bound on the gonality of $\text{Ig}(p^r)$ has been proved already by Schweizer, in a strong form:

**Theorem 4.1** ([Schweizer2005, Lemma 1.5(d,e)]).

(i) If $p \geq 7$, then \( \frac{p+13}{24} \leq \gamma_{\mathbb{F}_p}^G(\operatorname{Ig}(p)) \leq \frac{p-1}{6} \).

(ii) If $e > 1$ and $p^e \notin \{25, 9, 8, 4\}$, then $\gamma_{\mathbb{F}_p}^G(\operatorname{Ig}(p^e)) = p \gamma_{\mathbb{F}_p}^G(\operatorname{Ig}(p^{e-1}))$.

In fact, \cite{Schweizer2005} proves many more results. The above are more than we need to deduce the following.

**Corollary 4.2.** Let $G$ be the inverse image under $S \rightarrow \mathbb{Z}_{p}^\times$ of an open subgroup of index $D$ in $\mathbb{Z}_{p}^\times$ containing $\{\pm 1\}$. Then $\gamma_{\mathbb{F}_p}^G(X_G) > D/12$.

**Proof.** First suppose that $X_G = \operatorname{Ig}(p^e)$ for some prime power $p^e > 2$. Then $D = p^{e-1}(p-1)/2$. For $p^e \leq 25$, we have $D < 12$, and $\gamma_{\mathbb{F}_p}^G(X_G) \geq 1 > D/12$ trivially. For $p > 25$, Theorem 4.1(ii) gives

$$\gamma_{\mathbb{F}_p}^G(\operatorname{Ig}(p)) \geq \frac{p + 13}{24} > \frac{p - 1}{24} = \frac{D}{12}.$$ 

For $p^e > 25$ with $e > 1$, we use induction on $e$, with Theorem 4.1(ii) giving the inductive step.

Any other $X_G$ in Corollary 4.2 is a quotient of $\operatorname{Ig}(p^e)$ for some $p^e > 2$, and the inequality for $X_G$ follows from the inequality for $\operatorname{Ig}(p^e)$, by Proposition 1.1(vi). \(\Box\)

**Remark 4.3.** An alternative approach to lower bounds on the gonality of Igusa curves is to show that they have many points over certain finite fields, to deduce that the gonality over these finite fields is large, and then to apply Theorem 2.5. One can no longer use supersingular points, however, since these are totally ramified in $\operatorname{Ig}(p^e) \rightarrow \mathbb{P}^1$, and hence their number does not grow with $e$. Instead we could use ordinary points: it follows from \cite[Corollary 2.13]{Pacheco1996} and Hurwitz class number estimates that $\# \operatorname{Ig}(q)(\mathbb{F}_q) \geq q^{1/2+o(1)}$ as $q \rightarrow \infty$. Or one could use cusps, as in the proof of \cite[Theorem 6.1]{Schweizer2004}, to get lower bounds on $\# \operatorname{Ig}(q)(\mathbb{F}_p)$, since the cusps split completely in $\operatorname{Ig}(p^e) \rightarrow \mathbb{P}^1$ \cite[Katz–Mazur 1985 Corollary 12.7.2]{Katz-Mazur1985}. But the lower bounds on gonality obtained by these methods are weaker than the ones we took from \cite{Schweizer2005}.

5. **Group theory**

Here we study the open subgroups of $S$. Let $S_p = \mathbb{Z}_p^\times$ and $S_{\neq p} = \prod_{\ell \neq p} \operatorname{SL}_2(\mathbb{Z}_\ell)$, so $S = S_p \times S_{\neq p}$. Given an open subgroup $G \leq S$, let $G_p$ and $G_{\neq p}$ be the images of $G$ in $S_p$ and $S_{\neq p}$, respectively.

**Lemma 5.1.** Let $B \in \mathbb{Z}_{>0}$. Any open subgroup $H$ of $S_{\neq p}$ of index $\leq B$ contains

$$\prod_{\ell \leq B!, \ell \neq p} \{1\} \times \prod_{\ell > B!, \ell \neq p} \operatorname{SL}_2(\mathbb{Z}_\ell).$$

**Proof.** For each $\ell \neq p$, identify $\operatorname{SL}_2(\mathbb{Z}_\ell)$ with a subgroup of $S_{\neq p}$ in the obvious way. It suffices to show that $H$ contains $\operatorname{SL}_2(\mathbb{Z}_\ell)$ for each $\ell > B!$ with $\ell \neq p$.

The kernel of the action of $S_{\neq p}$ on the coset space $S_{\neq p}/H$ is a normal open subgroup $N \leq S_{\neq p}$ contained in $H$. Let $n := (S_{\neq p} : N)$, so $n \leq B!$. Now $\ell > B! \geq n$, so $1/n \in \mathbb{Z}_\ell$, and

$$\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 1/n \\ 0 & 1 \end{pmatrix}^n \in N,$$
where the matrices belong to $\text{SL}_2(\mathbb{Z}_\ell) \leq S_{\neq p}$. Similarly $\begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \in N$. But these two matrices generate the dense subgroup $\text{SL}_2(\mathbb{Z})$ of $\text{SL}_2(\mathbb{Z}_\ell)$, so $\text{SL}_2(\mathbb{Z}_\ell) \leq N \leq H$. □

**Lemma 5.2.** For each $B > 0$, there are at most finitely many open subgroups $G$ of $S$ such that $(S_p : G_p) < B$ and $(S_{\neq p} : G_{\neq p}) < B$.

**Proof.** Fix $B$. By Lemma 5.1 it suffices to consider instead the situation in which $S_{\neq p}$ is replaced by $S_L := \prod_{\ell \in L} \text{SL}_2(\mathbb{Z}_\ell)$ for a finite set $L$ of primes $\neq p$: i.e., $G$ is now an open subgroup of $S_p \times S_L$, $G_L$ is the image of $G$ in $S_L$, and we are given $(S_p : G_p) < B$ and $(S_L : G_L) < B$.

Since $S_p$ and $S_{\neq p}$ are topologically finitely generated, there are finitely many possibilities for $G_p$ and $G_L$. Goursat’s Lemma [LangAlgebra, p. 75] states that each possible $G$ is the inverse image under $G_p \times G_L \twoheadrightarrow G_p \times G_L \\ H_p \times H_L$

of the graph of an isomorphism

$$
\frac{G_p}{H_p} \rightarrow \frac{G_L}{H_L}
$$

for some normal open subgroups $H_p \leq G_p$ and $H_L \leq G_L$. By the finite generation again, it suffices to bound $(G_p : H_p) = (G_L : H_L)$. It is bounded by the supernatural number $\gcd(\#S_p, \#S_L)$, which is finite, since $S_p$ has a pro-$p$ open subgroup, while $S_L$ has an open subgroup of order prime to $p$. (See SerreGaloisCohomology I.13 for the notion of supernatural number.) □

6. THE GENERAL CASE OF THEOREM 1.4

**Proof of Theorem 1.4.** Let $m > 0$. We will show that $\gamma_{\overline{F}_p}(X_{G_i}) > m$ for all but finitely many $i$. Let $\Phi_{p}$ be as in Corollary 3.3. Choose $B_0$ such that $\min\{\Phi_{p}(B), B/12\} > m$ for all $B \geq B_0$. By Lemma 5.2 all but finitely many $G_i$ in our sequence have either $(S_p : (G_i)_{p}) \geq B$ or $(S_{\neq p} : (G_i)_{\neq p}) \geq B$. For each such $i$, $X_{G_i}$ dominates an $X_G$ with $G$ as in Corollary 3.3 or Corollary 1.2: then $\gamma_{\overline{F}_p}(X_G)$ exceeds either $\Phi_{p}(B)$ or $B/12$. By Proposition 1.4 (vii),

$$
\gamma_{\overline{F}_p}(X_G) \geq \gamma_{\overline{F}_p}(X_G) \geq \min\{\Phi_{p}(B), B/12\} > m.
$$

□

7. IMAGE OF GALOIS

**Proof of Theorem 1.5.** We may assume that $k$ is algebraically closed. By Theorem 1.4 there are only finitely many subgroups $G \leq S$ containing $\{\pm 1\}$ such that $\gamma_{\overline{F}_p}(X_G) \leq d$. Choose $N_{p,d}$ such that $N_{p,d} \geq 2(S : G)$ for every such $G$.

Let $K$ be a field of degree $\leq d$ over $k(t)$, and let $E$ be an elliptic curve over $K$ with $j(E)$ not algebraic over $k$ (i.e., not in $k$). Write $K = k(C)$, where $C$ is a curve over $k$ with $\gamma_k(C) \leq d$. Define $H := \rho_{E}(\text{Gal}(K^s/K))$. Since $k$ is algebraically closed, $H \subseteq S$. We want $(S : H) \leq N_{p,d}$.

Suppose not. If $(S : H)$ is infinite, then since $S/H$ is a profinite group, we can find a group $H'$ with $H \leq H' \leq S$ and $N_{p,d} < (S : H') < \infty$. If $(S : H)$ is finite, let $H' = H$. In either case, let $H''$ be the group generated by $H'$ and $-1$, so $N_{p,d}/2 < (S : H'') < \infty$. 

8
By definition of $N_{p,d}$, the group $H''$ does not equal any of the groups $G$, so $\gamma_{\mathbb{F}_p}(X_{H''}) > d$. Equivalently, by Proposition 1.1(ii), $\gamma_k(X_{H''}) > d$.

The curve $X_{H''}$ is defined as a quotient of some $X(p^e; N)$. Choosing level structure for $E$ over $K^s$ gives a point in $X(p^e; N)(K^s)$, and the action of $\text{Gal}(K^s/K)$ moves this point within the $H''$-orbit, since $H \subseteq H''$, so the image point in $X_{H''}(K^s)$ is $K^s$-rational. This point in $X_{H''}(K)$ may be viewed as a rational map $C \dashrightarrow X_{H''}$, and this map is non-constant since the composition $C \dashrightarrow X_{H''} \dashrightarrow X(1) \cong \mathbb{P}^1$ corresponds to $j(E) \in K - k$. Proposition 1.1(vii) implies $\gamma_k(X_{H''}) \leq \gamma_k(C) \leq d$, contradicting the previous paragraph.

\[ \square \]

Acknowledgements

Most of all I thank Andreas Schweizer for several discussions, for suggesting several references, and for pointing out that existing versions of the Castelnuovo-Severi inequality seem to require a perfect field of constants. I also thank Matt Baker, from whom I first learned the idea in [Harris-Silverman1991] that the Castelnuovo-Severi inequality could be used to bound change in gonality under algebraic extensions. I thank Brian Osserman for pointing out that the lower bound on the geometric gonality of the general curve of genus $g$ in characteristic $p$ could be deduced from [Osserman2005]. I thank Doug Ulmer for a remark about cusps of Igusa curves. Finally I thank Alina Cojocaru, Chris Hall, Dinesh Thakur, and Doug Ulmer for asking questions that inspired this paper.
