Aims: Influenced by microenvironment, human peritoneal mesothelial cells (HPMCs) acquired fibrotic phenotype, which was identified as the protagonist for peritoneal fibrosis. In this study, we examined the role of histone deacetylase 6 (HDAC6) for interleukin-6 (IL-6) induced epithelial-mesenchymal transition (EMT), proliferation, and migration of HPMCs.

Methods: The role of HDAC6 in IL-6-elicited EMT of HPMCs was tested by morphological observation of light microscope, immunoblotting, and immune-fluorescence assay; and the function of HDAC6 in proliferation and migration of HPMCs was examined by CCK-8 assay, wound healing experiment, and immunoblotting.

Results: IL-6 stimulation significantly increased the expression of HDAC6. Treatment with tubastatin A (TA), a highly selective HDAC6 inhibitor, or silencing of HDAC6 with siRNA decreased the expression of HDAC6. Moreover, TA or HDAC6 siRNA suppressed IL-6-induced EMT, as evidenced by decreased expressions of α-SMA, Fibronectin, and collagen I and the preserved expression of E-cadherin in cultured HPMCs. Mechanistically, HDAC6 inhibition suppressed the expression of transforming growth factor β (TGFβ) receptor I (TGFβRI), phosphorylation of Smad3, secretion of connective tissue growth factor (CTGF), and transcription factor Snail. On the other hand, the pharmacological inhibition or genetic target of HDAC6 suppressed HPMCs proliferation, as evidenced by the decreased optical density of CCK-8 assay, wound healing experiment, and immunoblotting.

Mechanistically, HDAC6 inhibition blocked the activation of JAK2 and STAT3.

Abbreviations: HPMCs, human peritoneal mesothelial cells; HDAC6, histone deacetylase 6; IL-6, interleukin-6; EMT, epithelial-mesenchymal transition; TA, tubastatin A; α-SMA, α-smooth muscle actin; TGFβ, transforming growth factor β, TGFβRI; TGF-β receptor I; CTGF, connective tissue growth factor; PD, peritoneal dialysis; PF, peritoneal fibrosis.
**INTRODUCTION**

Peritoneal dialysis (PD) is an effective and home-based renal replacement therapy for end-stage renal disease (ESRD) patients (Li et al., 2017). Peritoneal fibrosis (PF) is the main factor for ultrafiltration loss and treatment failure in PD patients, and it is characterized by the loss of mesothelial cells (MCs) and increase of myofibroblasts in submesothelial areas, where epithelial-mesenchymal transition (EMT) occurs (Zhou Q. et al., 2016).

The EMT process refers to the trans-differentiation of epithelial cells into motile mesenchymal cells, which is regulated by related transcriptional factors, such as Snail and Twist, resulting in upregulation of mesothelial cell markers (i.e., α-SMA, Collagen I, and Fibronectin) and downregulation of epithelial cell markers (i.e., E-cadherin and ZO-1) (Lamouille et al., 2014). Meanwhile, peritoneal mesothelial cells under phenotypic transformation often acquire the capacity of proliferation and invasiveness and secrete more cell cycle associated proteins, such as proliferating cell nuclear antigen (PCNA) and Cyclin E (He et al., 2015). Traditionally, this proliferation and invasiveness and secrete more cell cycle regulators activity controls both cytoplasmic and nuclear functions (Pulya et al., 2021). The best characterized substrate for HDAC6 is α-tubulin (Hubbert et al., 2002). HDAC6 deacetylates α-tubulin via a process that requires its second HDAC domain and leads to an increase in the cell motility (Hubbert et al., 2002). Moreover, we and other research groups found that, unlike classes I, IIa, and III HDACs knockout mice, the homozygous HDAC6-deficient mice, which presented hyperacetylated tubulin in quite a lot tissues, were viable and fertile (Zhang et al., 2008; Chen et al., 2020). This indicated that HDAC6-specific inhibitors could be a safer and better tolerated medicine than pan-HDAC inhibitors. Recently, some of HDAC6 selective inhibitors, such as ACY-1215 (IC50 = 4.8 nM) and ACY-241 (IC50 = 2.6 nM), had been underwent the Phase I/II clinical trials in the field of tumors treatment (Porter et al., 2017; Pulya et al., 2021).

Comparing these molecules, tubastatin A (TA) inhibited HDAC6 with an IC50 of 15 nM. Even so, TA was still a potential candidate because of its high selectivity. TA was found to have about 1093 fold selectivity towards HDAC6 over classes I HDACs, while ACY-1215 and ACY-241 had 12-fold and 18-fold selectivity, respectively (Porter et al., 2017; Pulya et al., 2021). Thus, TA was adopted and administrated at different concentrations in the current study.

Acetylation is an important epigenetics modification in histone tail, which is regulated by histone acetyltransferases (HATs) and histone deacetylases (HDACs) (West and Johnstone, 2014). Histone deacetylase 6 (HDAC6) belongs to class IIb and primarily resides in the cytoplasm, while its deacetylase activity controls both cytoplasmic and nuclear functions (Pulya et al., 2021). The best characterized substrate for HDAC6 is α-tubulin (Hubbert et al., 2002). HDAC6 deacetylates α-tubulin via a process that requires its second HDAC domain and leads to an increase in the cell motility (Hubbert et al., 2002). Moreover, we and other research groups found that, unlike classes I, IIa, and III HDACs knockout mice, the homozygous HDAC6-deficient mice, which presented hyperacetylated tubulin in quite a lot tissues, were viable and fertile (Zhang et al., 2008; Chen et al., 2020). This indicated that HDAC6-specific inhibitors could be a safer and better tolerated medicine than pan-HDAC inhibitors. Recently, some of HDAC6 selective inhibitors, such as ACY-1215 (IC50 = 4.8 nM) and ACY-241 (IC50 = 2.6 nM), had been underwent the Phase I/II clinical trials in the field of tumors treatment (Porter et al., 2017; Pulya et al., 2021). Comparing these molecules, tubastatin A (TA) inhibited HDAC6 with an IC50 of 15 nM. Even so, TA was still a potential candidate because of its high selectivity. TA was found to have about 1093 fold selectivity towards HDAC6 over classes I HDACs, while ACY-1215 and ACY-241 had 12-fold and 18-fold selectivity, respectively (Porter et al., 2017; Pulya et al., 2021). Thus, TA was adopted and administrated at different concentrations in the current study.

Notably, previous studies reported that HDAC6 promoted kidney and lung fibrosis, mainly through its regulation and activation on growth factor receptors (Deribe et al., 2009; Saito et al., 2017; Chen et al., 2020). However, the role of HDAC6 in the inflammatory factor IL-6 signaling pathway remains unexplored. IL-6 was accounted for a significant concentration in the drained dialysate and thus adopted to stimulate human peritoneal mesothelial cells (HPMCs). Interestingly, we observed that HDAC6 was overexpressed after stimulation; meanwhile HPMCs tended to EMT, proliferation, and migration. What is the role of this IL-6-induced deacetyase for cell phenotype and mobility? Does it have a modification on the downstream signaling of IL-6? Could it be a linker between IL-6 and TGF-β signaling?

In this study, we first assessed the effect of TA on the IL-6-induced change of the phenotype and the mobility of HPMCs and...
further investigated the signaling regulatory mechanism, in order to provide evidence for future clinical trials in the field of peritoneal fibrosis.

MATERIALS AND METHODS

Antibodies and Reagents
Tubastatin A and MG132 were purchased from Selleckchem (Houston, TX, United States). Antibodies to HDAC6 (#7612), Acetyl Histone H3 (Lys9) (#9649), Histone H3 (Lys9) (#9717), Acetyl α-Tubulin (Lys40) (#5335), α-Tubulin (#3873), ZO-1 (#13663), Smad3 (#9523), p-Smad3 (#9520), JAK2 (#3230), p-JAK2 (#3771), STAT3 (#9139), p-STAT3 (#9138), CTGF (#86641), E-cadherin (#14472), Cyclin E (#20808) and Snail (#3879) were purchased from Cell Signaling Technology (Danvers, MA, United States). Antibody to Fibronectin (ab2413) was purchased from Abcam (Cambridge, MA). Antibodies to GAPDH (sc-32233), Collagen I (A2) (sc-8654), TGFβRI (sc-399), Smad7 (sc-365846), and PCNA (sc-71858) were purchased from Santa Cruz Biotechnology (San Diego, CA, United States). IL-6 protein was purchased from R&D Systems (Minneapolis, MN, United States). HDAC6 siRNA was purchased from GenePharma (Shanghai, China). Lipofectamine 2000 was purchased from Invitrogen (Grand Island, NY, United States). The Cell Counting Kit-8 (CCK-8) proliferation assay kit was purchased from Beyotime Biotechnology (Haimen, China). Antibody to α-SMA (A2547) and all other chemicals were obtained from Sigma-Aldrich (St. Louis, MO, United States).

Mesothelial Cell Culture
Human peritoneal mesothelial cells (HPMCs) (Jennio Biotechnology, Guangzhou, China) were cultured in MEM containing 10% fetal bovine serum (FBS) and 1% penicillin and streptomycin in an atmosphere of 5% CO2 and 95% air at 37°C. To determine the effect of HDAC6 inhibition on EMT induced by IL-6, the HPMCs were starved for 24 h with 0.5% FBS in MEM and then exposed to IL-6 (100 ng/ml) for 36 h in the presence or absence of different concentrations of TA (5, 10, and 20 µM) or MG132 (5 µM) before cell harvesting. All of the in vitro experiments were repeated for at least three times.

siRNA Transfection
The small interfering (si) RNA oligonucleotides targeted specially for HDAC6 were used to downregulate the HDAC6 level in the cultured human peritoneal mesothelial cells. The HPMCs were seeded to 30–40% confluence in antibiotic-free medium and grown for 24 h and then were transfected with HDAC6 siRNA (50 nmol) with Lipofectamine 2000 according to the manufacturer’s instructions. In parallel, scrambled siRNA (50 nmol) was used as control for the off-target changes in the HPMCs. After transfection for 24 h, the cells were treated with IL-6 (100 ng/ml) for an additional 36 h before being harvested for further experiments.

CCK-8 Proliferation Assay
The CCK-8 proliferation kit was used according to the manufacturer’s instructions. The HPMCs were starved for 24 h with MEM containing 0.5% FBS and then exposed to IL-6 (100 ng/ml) in the presence or absence of TA (5, 10, and 20 µM). After 36 h, the original culture medium was removed, and 100 µl new MEM medium containing 10 µl CCK-8 was added to each well in a 96-well plate for 37°C incubation for an additional 4 h. The final optical density values were read at 450 nm.

Immunoprecipitations and Immunoblotting
Following an initial 24 h starvation, the HPMCs were exposed to IL-6 (100 ng/ml) for 36 h. The cell lysate was harvested by using ice-cold non-denaturing lysis buffer (Thermo Scientific, Rockford, IL). Co-immunoprecipitation (co-IP) was done using the Thermo Scientific Pierce co-IP kit (26149) following the manufacturer’s protocol. Briefly, the HDAC6 or IgG antibody was first immobilized for 2 h using AminoLink Plus coupling resin. The resin was then washed and incubated with the cell lysate overnight. After incubation, the resin was again washed and the protein was eluted using the elution buffer. The samples were analyzed by immunoblotting using the antibodies of Smad3, HDAC6, and GAPDH. Immunoblotting was performed as previously described (Zhou X. et al., 2016). The densitometry analysis of immunoblotting results was conducted by using ImageJ software.

Wound Healing Assay
The HPMCs were seeded in a 6-well plate and allowed to reach 90% confluence. A scratch wound was created on the cell surface using a micropipette tip. Then, the cells were washed with PBS three times and incubated in serum-free MEM with IL-6 (100 ng/ml) in the presence or absence of TA (20 µM) and HDAC6 siRNA. The photomicrographs (×40 objective magnification) of the migrating cells were taken at 0–36 h. The width of the wound was measured using ImageJ software (National Institutes of Health, Bethesda, MD, United States). The migratory rate was calculated as (A−B)/A × 100%, where A and B reflect the width of the wound at 0–36 h, respectively.

Immunofluorescence Staining
The cells grown on chamber slides were fixed for 15 min with 4% paraformaldehyde. The samples were permeabilized with 0.1% Triton X-100 for 30 min. Then, the samples were blocked with goat serum for 15 min. The primary antibodies against HDAC6, Acetyl Histone H3, α-SMA, Fibronectin, E-cadherin, and ZO-1 were added to the samples, respectively, and incubated overnight at 4°C. After PBS washing, the cells were incubated with the Texas Red-labeled secondary antibody (1:200, Beyotime, China) diluted in PBS for 1 h at room temperature. The nuclei were stained with DAPI. After additional washing for 5 min three times, the samples were sealed by the antifade reagent and visualized with an Olympus fluorescence microscope (at ×200 magnification).

Statistical Analysis
All the experiments were conducted at least three times. The data depicted in the graphs represent the means ± SEM for each group. The intergroup comparison was made using one-way analysis of
variance. Multiple means were compared using Tukey’s test. The differences between the two groups were determined by Student’s t-test. The statistical significant difference between the mean values was marked in each graph. $p < 0.05$ was considered significant. The statistical analyses were conducted by using IBM SPSS Statistics 20.0 (Version X; IBM, Armonk, NY, United States).

RESULTS

**IL-6 Increases the Expression of HDAC6 in Cultured Peritoneal Mesothelial Cells**

IL-6 was a canonical inflammation factor, which was highly expressed in the fibrotic peritoneum and the dialysis effluent from long-term PD patients (Lopes Barreto et al., 2011; Yang et al., 2012).
et al., 2014; Yang et al., 2018). We aimed to investigate the mechanism by which IL-6 regulated the peritoneal fibrosis. Firstly, the human peritoneal mesothelial cells were stimulated by IL-6 in vitro. We found that the exposure of HPMCs to IL-6 at 100 ng/ml changed the cell morphology into fusiform or spindle shape (Figure 1A) and increased the expression level of HDAC6 and decreased the expression of Acetyl Histone H3 and Acetyl α-Tubulin in the cultured HPMCs (Figures 1B–D). The treatment of cells with TA, a highly selective inhibitor of HDAC6 (Shi et al., 2014; Yang et al., 2018), decreased the expression of Acetyl Histone H3 and Acetyl α-Tubulin in the cultured HPMCs (Figures 1B–D). The treatment of cells with TA, a highly selective inhibitor of HDAC6, at different concentrations (5, 10, and 20 μM) resulted in decreasing the expression of HDAC6 and increasing the expression of Acetyl Histone H3 (Figures 1B,C) and Acetyl α-Tubulin (Figures 1B,D) in a concentration-dependent manner, with a maximum effect at 20 μM. Neither IL-6 stimulation nor TA treatment had an impact on total expression of Histone H3 and α-Tubulin (Figure 1B). In addition, the immunofluorescent staining of HPMCs showed that HDAC6 was mainly expressed in both nucleus and the cytosol, while TA treatment decreased IL-6-induced HDAC6 and improved Acetyl Histone H3 (Figures 1E,F). Notably, we found that TA not only inhibited the activity of HDAC6 but also reduced the expression of HDAC6. We speculated that HDAC6 played an essential role in dictating the IL-6-elicited EMT. To further verify the role of HDAC6 in EMT, we tested the effect of HDAC6 knockdown on the EMT of HPMCs using specific siRNA. As shown in Figure 3A, the cell morphology was slightly turned into oval or cobblestone shape after HDAC6 inhibition. siRNA-mediated silencing of HDAC6 recovered the abnormally low expression of Acetyl Histone H3 and Acetyl α-Tubulin induced by IL-6 but did not alter the level of total Histone H3 and α-Tubulin (Figures 3B–D). As expected, HDAC6 siRNA also downregulated α-SMA, Fibronectin, and Collagen I and upregulated the expression of E-cadherin (Figures 3E–G). These data further confirmed the importance of HDAC6 in mediating IL-6 induced EMT of peritoneal mesothelial cells.

**Pharmacological Blockade of HDAC6 Inhibits IL-6 Induced EMT of Cultured Human Peritoneal Mesothelial Cells**

Beside the canonical TGF-β-directed EMT pathway, inflammatory cytokine IL-6 also facilitated the EMT of the peritoneal mesothelial cells (Xiao et al., 2017), while the specific mechanism was still obscure. Considering the high expression of HDAC6 under the IL-6 stimulation, we hypothesized that HDAC6 would play an essential role in IL-6-triggered EMT of HPMCs. To test this hypothesis, we examined the effect of HDAC6 inhibition on IL-6-induced EMT of peritoneal mesothelial cells. As shown in Figure 2, exposure to IL-6 promoted the EMT of HPMCs, showing the increased expression of mesenchymal cell markers (α-SMA, Fibronectin, and Collagen I) and the decreased expression of epithelial cell marker, E-cadherin (Strippoli et al., 2016). Inhibition of HDAC6 with TA markedly suppressed IL-6-induced expression of α-SMA, Fibronectin, and Collagen I and prevented E-cadherin loss (Figures 2A–C). In parallel, immunofluorescent staining had a similar phenomenon. TA treatment downregulated the expressions of α-SMA and Fibronectin and upregulated the expressions of E-cadherin and ZO-1 (Figures 2D–G). The results indicated that the inhibition of HDAC6 by TA could effectively alleviate IL-6-induced EMT of HPMCs.

**siRNA-Mediated Silencing of HDAC6 Inhibits EMT of Peritoneal Mesothelial Cells**

To further verify the role of HDAC6 in EMT, we tested the effect of HDAC6 knockdown on the EMT of HPMCs using specific siRNA. As shown in Figure 3A, the cell morphology was slightly turned into oval or cobblestone shape after HDAC6 inhibition. siRNA-mediated silencing of HDAC6 recovered the abnormally low expression of Acetyl Histone H3 and Acetyl α-Tubulin induced by IL-6 but did not alter the level of total Histone H3 and α-Tubulin (Figures 3B–D). As expected, HDAC6 siRNA also downregulated α-SMA, Fibronectin, and Collagen I and upregulated the expression of E-cadherin (Figures 3E–G). These data further confirmed the importance of HDAC6 in mediating IL-6 induced EMT of peritoneal mesothelial cells.

**HDAC6 Is Required for the Activation of the TGF-β Signaling Pathway in Peritoneal Mesothelial Cells**

It was reported that IL-6 could trigger the activation of the TGF-β signaling pathway in the fibrosis process (Luckett-Chastain et al., 2017); however, the cross-talk mechanism was obscure. We speculated that IL-6-elicited HDAC6 was required for the activation of the TGF-β signaling pathway, leading to an increased secretion of growth factors, such as CTGF, and the increased expression of transcription factors, such as Snail. To test this hypothesis, we examined the expression of TGF-β type receptor I (TGFβRI) on the TA-inhibited peritoneal mesothelial cells. As shown in Figures 4A,B, the base level of TGFβRI was negligible in the starved cell. However, its expression level was substantially elevated after IL-6 stimulation, which was further inhibited by TA treatment in a dose-dependent manner. TA also suppressed the phosphorylation of Smad3, while it restored the expression of Smad7, which could block the activation of Smad2/3 by competitively binding with TGFβRI (Murayama et al., 2020). There was no impact on total Smad3 (Figures 4A–D). Moreover, the immunoblot results presented that TA decreased the secretion of the growth factor CTGF in the IL-6-stimulated HPMCs (Figures 4E,F); and the nuclear transcription factor Snail, which was responsible for transcription inhibition of E-cadherin (Zhang et al., 2018; Wang et al., 2020), also witnessed a decrease after TA treatment (Figures 4G,H). Similarly, HDAC6 siRNA inhibited accumulation of TGFβRI, phosphorylation of Smad3, and loss of Smad7 (Figures 5A–D). It also had an inhibition effect on the expressions of CTGF and Snail (Figures 5E–H). These results suggested that HDAC6 was required for the activation of the TGF-β/Smad3 signaling pathway, resulting in the secretion of CTGF and upregulation of Snail (Figure 8).

Additionally, we conducted the immunoprecipitation experiment to find the direct substrate of HDAC6.
The starved HPMCs were exposed to IL-6 (100 ng/ml) for 36 h and then harvested and prepared for immunoprecipitation and immunoblot. The result showed an interaction between HDAC6 and Smad3 in HPMCs treated with IL-6. Therefore, we speculated that HDAC6 directly interacted with Smad3 in the cytoplasm, and deacetylated Smad3 tended to nuclear localization and phosphorylation.

Inhibition of HDAC6 with TA or siRNA Alleviates Proliferation and Migration Through the JAK2/STAT3 Signaling Pathway in HPMCs.

It was reported that HPMCs underwent EMT acquired the ability of cell cycle progression, cell proliferation, and cell mobility (He et al., 2015). Thus, we assessed the role of HDAC6 in regulating...
siRNA-mediated silencing of HDAC6 inhibits EMT of peritoneal mesothelial cells. (A) Cell morphology was observed using light microscopy. The red arrows indicated the cobblestone-shaped cells and the yellow arrows showed the spindle-shaped cells. (B) Cell lysates were subjected to immunoblot analysis with antibodies against HDAC6, Acetyl Histone H3, Histone H3, Acetyl α-Tubulin, α-Tubulin, and GAPDH. (C) Expression levels of HDAC6 and Acetyl Histone H3 were quantified by densitometry and normalized with GAPDH and total histone H3, respectively. (D) Expression level of Acetyl α-Tubulin was quantified by densitometry and normalized with total α-Tubulin. (E) Cell lysates were subjected to immunoblot analysis with specific antibodies against α-SMA, Fibronectin, Collagen I, E-cadherin, and GAPDH. (F) Expression levels of α-SMA, Fibronectin, and Collagen I were quantified by densitometry and normalized with GAPDH. (G) Expression level of E-cadherin was quantified by densitometry and normalized with GAPDH. Data are represented as the mean ± SEM (n = 3). Means with different superscript letters are significantly different from one another (p < 0.05). All scale bars = 100 μm.
the proliferation of HPMCs by the CCK-8 assay. The results showed that IL-6 at 100 ng/ml substantially stimulated the cell proliferation of HPMCs, compared with the simple starved group, while the TA treatment kept down the proliferation level, especially at the concentration of 20 μM (Figure 6A). The immunoblot analysis further confirmed the ability of TA in inhibiting cell proliferation, as indicated by decreased expression levels of PCNA and Cyclin E, two proliferating
hallmarks (Figures 6B–D). In addition, the cell migration test showed that TA suppressed the migratory rate of HPMCs (Figures 6E,F). To further reveal the mechanism in TA-downregulated proliferation and migration, we tested the expressions of JAK2 and STAT3 before and after the TA treatment in IL-6-stimulated HPMCs. The immunoblot
analysis showed that TA suppressed the phosphorylation of JAK2 and STAT3 in a concentration-dependent manner, while the total protein was not impacted (Figures 6G,H). Additionally, we found that siRNA-mediated silencing of HDAC6 achieved similar results (Figure 7). Taken together, these data illustrated that HDAC6 promoted the proliferation and migration of HPMCs through regulating the JAK2/STAT3 signaling (Figure 8).

**DISCUSSION**

The mesothelial cells which transferred to the mesenchymal phenotype acquired the increased capacity of proliferation, migration, and extracellular matrix (ECM) secretion, forming a fibrosis scar (Zhou Q. et al., 2016). Beside the canonical TGF-β, the inflammation factor IL-6 was also an important fibrosis inducer, which had a significant amount in the drained...
dialysate from the PD patients (Lopes Barreto et al., 2011; Yang et al., 2014; Yang et al., 2018). However, the specific mechanism in the IL-6-induced cell phenotype change was still obscure. The current study firstly unravels a pivotal role of IL-6-elicited HDAC6 in signaling regulation and in EMT, proliferation, and migration of HPMCs.

It had been well established that TGF-β1 triggers EMT. Indeed, IL-6 also had this capacity, which was an indirect process through coactivating the TGF-β signaling pathway (Luckett-Chastain et al., 2017). Although the IL-6/TGF-β cooperation in the realm of ECM deposition had been documented (Luckett-Chastain et al., 2017; Epstein Shochet et al., 2020), their modulatory link was obscure. Our current study found that IL-6 stimulation induced the overexpression of HDAC6 in HPMCs. HDAC6 might be a vital linker between two signalings. The best characterized substrate for HDAC6

FIGURE 7 | siRNA-mediated silencing of HDAC6 inhibits proliferation and migration through the JAK2/STAT3 signaling pathway in human peritoneal mesothelial cells. (A) Cell lysates were subjected to the immunoblot analysis with specific antibodies against PCNA, Cyclin E, and GAPDH. (B) Expression levels of PCNA and Cyclin E were quantified by densitometry and normalized with GAPDH. was α-Tubulin, an important component of the cytoskeleton, which had been reported to closely contact with clathrin, a receptor endocytosis-related protein (Rappoport et al., 2003; Montagnac et al., 2013). Evidence showed that clathrin moved along the microtubule cytoskeleton parallel to the cell surface (Rappoport et al., 2003; Montagnac et al., 2013). Acetylation of α-Tubulin tended to form a polymerization of microtubule and resulted in modest reduced endocytosis, while deacetylated α-Tubulin facilitated the insertion of the complexes in the clathrin-coated pits (Thomas et al., 2016; Melgari et al., 2020). Given that the TGF-β receptors were constitutively internalized via clathrin-dependent or lipid raft-dependent endocytic pathways (Kardassis et al., 2009), we suggested that IL-6 might modulate the activity of TGFβRI through upregulating deacetylase HDAC6, deacetylating α-Tubulin, and subsequent promoting clathrin internalization. This was evidenced by our present data demonstrating that HDAC6 inhibition increased the acetylation of α-Tubulin, decreased the expression of TGFβRI, and the activation of the TGF-β network in IL-6 treated HPMCs. But how does IL-6 increase the expression and activity of HDAC6? It might also work through an epigenetic mechanism. The detailed mechanism waited further investigation.

Our study also found that HDAC6 affected the activity of Smad3 in IL-6-treated HPMCs. The activation of Smad3 was not just the downstream effector of the TGF receptor. The emerging evidence implicated that the microtubule structure regulated the Smads activity (Dong et al., 2000; Zhu et al., 2004). Binding of Smads to microtubules kept Smads in their inactive stage, and TGF-β1 could trigger the release of Smads from microtubules and the subsequent phosphorylation of Smads (Dong et al., 2000; Zhu et al., 2004). Thus, one possible mechanism is that HDAC6 modulated the Smad3 activity through deacetylating α-Tubulin and promoting the release of Smad3. Another mechanism of Smad3 activation might be a direct acetylation modification by HDAC6 itself. A recent study reported the requirement of HDAC6 for the epidermal growth factor- (EGF-) triggered nuclear localization of β-catenin (Li et al., 2008). The deacetylation of lysine 49 in β-catenin was suggested to be essential for nuclear localization of β-catenin. It was conceivable that HDAC6 regulated nuclear localization of Smad3 via deacetylating Smad3 or Smad3-interacting proteins.

As expected, the immunoprecipitation experiment confirmed a direct interaction between HDAC6 and Smad3 in HPMCs treated with IL-6. Subsequently, intranuclear Smad3 recruited and activated the transcription factor Snail and promoted the expression of the ECM protein and the secretion of CTGF. Our results showed that HDAC6 was required for the phosphorylation of Smad3, while it did not affect the total expression of Smad3. Interestingly, Smad7, a Smad3 blocker in the TGFβ network, encountered a significant increase following the HDAC6 inhibition. Collectively, we suggested that HDAC6 was required for IL-6-elicited TGF-β signaling transduction through upregulation of TGFβRI, activation of Smad3, and downregulation of Smad7. Nevertheless, the mechanisms underlying HDAC6-mediated Smad signaling need further investigation.

Another important transcription factor in IL-6 signaling was STAT3, which was responsible for cell proliferation and invasion (Cheng et al., 2020). We speculated that activation of JAK2/STAT3 might relate to deacetylation of α-Tubulin. Like many other transcription factors, STAT3 possessed a coiled-coil domain, which was found in a variety of tubulin-binding proteins (Zhang et al., 2000; Tala et al., 2014). In leukemia cells, STAT3 was mainly concentrated in the centrosome region where microtubules were more stable and hyperacetylated (Yan et al., 2015). It was possible that deacetylation of α-Tubulin promoted the activation and nuclear translocation of STAT3, which might generate a positive feedback and affect phosphorylation of JAK2, contributing to an amplifying IL-6/JAK2/STAT3 signaling. Thus, the cell cycle associated proteins (i.e., PCNA and Cyclin E) increased and resulted in cell proliferation. Moreover, HDAC6 also promoted the cell migration. It was documented that the interaction between deacetylated α-Tubulin and STAT3 changed the stability of microtubule and activated the small GTPase Rac-1 or Rho to control actin-dependent membrane ruffling and cell motility (Hubbert et al., 2002). Consistently, HDAC6 inhibition reduced the STAT3 response and blocked the feedback for JAK2, slowing down the proliferation and migration of HPMCs.
In conclusion, the current study firstly found that IL-6-induced deacetylase HDAC6 not only regulated IL-6 itself downstream the JAK2/STAT3 signaling but also co-activated the TGF-β/Smad3 signaling, leading to the change of the phenotype and mobility of cells. This finding partially interpreted the mechanism of the development of peritoneal fibrosis under the inflammation microenvironment. HDAC6 could be a potential therapeutic target for the prevention and treatment of peritoneal fibrosis.

DATA AVAILABILITY STATEMENT
The original contributions presented in the study are included in the article/Supplementary Material; further inquiries can be directed to the corresponding author.

ETHICS STATEMENT
The animal study was reviewed and approved by the Ethics Committee of Shanghai East Hospital, Tongji University School of Medicine of China.

AUTHOR CONTRIBUTIONS
NL participated in the research design. YS, JN, MT, LT, XM, FL, HC, YH, and XZ conducted the experiments. YS, MT, and JN contributed new reagents or analytic tools. YS and JN performed HC, YH, and XZ conducted the experiments. YS, MT, and JN contributed to the writing of the manuscript. All authors approved the final version of the manuscript.

FUNDING
This study was supported by the Shanghai Scientific Committee of China (20ZJR1445800 and 13PJ1406900 to NL), the National Natural Science Foundation of China (Grants 82070791, 81670690, 81470991, and 81200492 to NL; 81700672 to JN; 81830021 and 81670623 to SZ; and 81970072 and 81500059 to LT), the Key Discipline Construction Project of Pudong Health Bureau of Shanghai (PWZxk 2017-05 to NL), the key program of Science Foundation of Jiangxi Province (2018ABC 20016 to LT), the leading medical talent project of Shanghai Pudong heath bureau (PWRI 2019-05 to LT), and Branch Grant of National Key R&D Program of China (2018YFA0108802 to SZ).

SUPPLEMENTARY MATERIAL
The Supplementary Material for this article can be found online at: https://www.frontiersin.org/articles/10.3389/fphar.2021.722638/full#supplementary-material

Supplementary Figure S1 | TA induces the degradation of HDAC6 through ubiquitin-proteasome pathway. (A) Cell lysates are subjected to immunoblot analysis with specific antibodies against HDAC6 and GAPDH. (B) Expression level of HDAC6 is quantified by densitometry and normalized with GAPDH. Data are represented as the mean ± S.E.M (n = 3). Means with different superscript letters are significantly different from one another (p < 0.05).

Supplementary Figure S2 | Smad3 is identified as a direct substrate of HDAC6. (A) Following an initial 24-h starvation, HPMCs are exposed to IL-6 (100 ng/ml) for 36 h. Total cellular proteins are harvested and immunoprecipitations are performed using HDAC6 or IgG antibody. And then immunoprecipitated proteins are immunoblotted with specific antibodies against Smad3, HDAC6 and GAPDH. An interaction between HDAC6 and Smad3 is found in HPMCs treated with IL-6.
