Exportin-5 mediates nuclear export of SRP RNA in vertebrates

Toshihiko Takeiwa, Ichiro Taniguchi and Mutsuhito Ohno*

Institute for Virus Research, Kyoto University, Kyoto 606-8507, Japan

The signal recognition particle is a ribonucleoprotein complex that is essential for the translocation of nascent proteins into the endoplasmic reticulum. It has been shown that the RNA component (SRP RNA) is exported from the nucleus by CRM1 in the budding yeast. However, how SRP RNA is exported in higher species has been elusive. Here, we show that SRP RNA does not use the CRM1 pathway in Xenopus oocytes. Instead, SRP RNA uses the same export pathway as pre-miRNA and tRNA as showed by cross-competition experiments. Consistently, the recombinant Exportin-5 protein specifically stimulated export of SRP RNA as well as of pre-miRNA and tRNA, whereas an antibody raised against Exportin-5 specifically inhibited export of the same RNA species. Moreover, biotinylated SRP RNA can pull down Exportin-5 but not CRM1 from HeLa cell nuclear extracts in a RanGTP-dependent manner. These results, taken together, strongly suggest that the principal export receptor for SRP RNA in vertebrates is Exportin-5 unlike in the budding yeast.

Introduction

The majority of the RNA species, following their synthesis and processing in the nucleus, are exported to the cytoplasm. It has been shown that different RNA species are exported from the nucleus via distinct export pathways, that is, by distinct sets of export factors (Jarmolowski et al. 1994; Komeili & O’Shea 2001; Cullen 2003). Among many RNA species, miRNA and spliceosomal U snRNA are initially m^7G-capped and this structure plays important roles for export of corresponding RNA species (Cullen 2003; Cheng et al. 2006; Nojima et al. 2007). In contrast, other RNA species such as rRNA, tRNA and major pre-miRNA do not possess the structure and instead their RNA bodies are highly structured. The small (18S) and large (25S in yeasts and 28S in vertebrates, respectively) rRNAs are commonly exported by CRM1 (Moy & Silver 1999; Gadal et al. 2001). However, Exportin-5 and Nxf1 also export the large rRNA in vertebrates and the budding yeast, respectively (Yao et al. 2007; Wild et al. 2010). Similarly, tRNA is exported by either Exportin-t or Exportin-5 (Arts et al. 1998; Kutay et al. 1998; Bohnsack et al. 2002; Calado et al. 2002), whereas major pre-miRNA by Exportin-5 (Yi et al. 2003; Bohnsack et al. 2004; Lund et al. 2004). Adenovirus VA1 RNA, which is also highly structured, is also exported by Exportin-5 (Gwizdek et al. 2001, 2003). Thus, it appears that Exportin-5 and CRM1 are two major export receptors for uncapped structured RNA species.

Another example of uncapped structured RNA species is the RNA component of the signal recognition particle (SRP) that is involved in the translocation of nascent polypeptides into the endoplasmic reticulum (ER) lumen (Egea et al. 2005). SRP is composed of 6 protein components, SRP9, 14, 19, 54, 68 and 72 in vertebrates, as well as the single RNA component, SRP RNA. Vertebrate SRP can be divided into 3 domains, Alu domain, S domain and the linker region that connects the other two domains. Alu domain consists of the 5’ and 3’ terminal regions of SRP RNA and the bound SRP9/14 protein heterodimer. S domain consists of the central region of SRP RNA, SRP19, SRP54 and the SRP68/72 heterodimer (see Fig. S1 in Supporting Information). The former domain is involved in the translational arrest activity of SRP, whereas the latter...
is involved in the recognition, as mediated by the bound SRP54 protein component, of both the signal sequence of nascent polypeptides and the SRP receptor on the ER membrane (Egea et al. 2005).

Experiments using the budding yeast, Xenopus oocytes and mammalian cells led to a proposal of an assembly model in which SRP RNA associates with all the protein components except SRP54 in the nucleolus, is then exported to the cytoplasm, and finally associates with SRP54 in the cytoplasm (He et al. 1994; Ciufò & Brown 2000; Politz et al. 2000, 2002; Grosshans et al. 2001; Sommerville et al. 2005). SRP RNA accumulates in the nucleus in the xpo1-1 ts mutant yeast strain at a nonpermissive temperature, suggesting CRM1 exports this RNA in the budding yeast (Ciufò & Brown 2000; Grosshans et al. 2001). It has been suggested that CRM1 may also export SRP RNA in vertebrates as leptomycin B (LMB) treatment of rat cells led to an increased SRP RNA signal in the nucleolus (Alavian et al. 2004). However, this could be an indirect effect of LMB as the authors discussed in the study because the LMB treatment has to be very long (as long as 20 h) to be able to see the effect, that is, shorter treatments did not lead to the SRP RNA accumulation. Moreover, association of CRM1 with SRP RNA has never been showed (neither in the case of the budding yeast). Thus, how SRP RNA is exported in higher species has been elusive. In this report, we carried out Xenopus oocyte RNA microinjection as well as biochemical experiments and gathered several lines of evidence to conclude that Exportin-5 but not CRM1 is the principal export receptor for SRP RNA in vertebrates.

**Results**

**SRP RNA is exported via a CRM1-independent pathway in Xenopus oocytes**

SRP RNA was previously suggested to use the CRM1-dependent export pathway in the budding yeast (Ciufò & Brown 2000; Grosshans et al. 2001). Whether or not vertebrate SRP RNA is also exported via the same CRM1 pathway was examined in the well-established Xenopus oocyte microinjection experiments. To this end, a well-characterized inhibitor of the CRM1-dependent export was used. This inhibitor was a conjugate of NES peptides coupled to BSA (BSA-NES), which was shown to saturate CRM1-dependent export (Fischer et al. 1995; Masuyama et al. 2004).

In the control situation, approximately 50% of the injected in vitro-transcribed $^{32}$P-labeled Xenopus SRP RNA as well as of DHFR mRNA had been exported to the cytoplasm during 1.5 h after nuclear microinjection, whereas the nonexported U6Ass RNA control stayed in the nucleus (Fig. 1A, lanes 5 and 6). Approximately 30% of U1ΔSm had been exported, whereas tRNA$^{\text{phe}}$ had been almost completely exported. When the same RNA mixture was injected with a saturating amount of BSA-NES, the export of DHFR mRNA and tRNA$^{\text{phe}}$ was hardly affected as DHFR mRNA uses NXF1/p15 and tRNA$^{\text{phe}}$ uses Exportin-t or Exportin-5 for export (Arts et al. 1998; Kutay et al. 1998; Komeili & O’Shea 2001; Bohnsack et al. 2002; Calado et al. 2002; Katahira 2012). In contrast, the export of U1ΔSm was severely inhibited as this RNA uses the CRM1–dependent export pathway (Fig. 1A, lanes 3 and 4 and Fig. 1B) (Fornerod et al. 1997). Remarkably, the export of Xenopus SRP RNA was unaffected (Fig. 1A, lanes 3 and 4 and Fig. 1B). Very similar results were obtained when human, instead of Xenopus, SRP RNA was used (Fig. 1C, D). These results suggested that vertebrate SRP RNA is exported via a CRM1-independent pathway.

**Vertebrate SRP RNA is exported via the common pathway with pre-miRNA and tRNA**

To further characterize the export pathway of vertebrate SRP RNA, we carried out cross-competition experiments (Jarmolowski et al. 1994). If SRP RNA shares the same export pathway with certain RNA specie (e.g., RNA A), export of SRP RNA should be specifically saturated and inhibited if a large amount of RNA A is co-injected. As SRP RNA is uncapped and structured, we first focused on pre-miRNA and tRNA as competitors. Co-injection of increasing amounts of human pre-miR-31 strongly inhibited export of Xenopus SRP RNA as well as of pre-miR-31 itself, whereas the nucleo-cytoplasmic distributions of U1ΔSm and U6Ass RNAs were unaffected (Fig. 2A). Export inhibition of SRP RNA was quite effective. Its export was inhibited by 93.4% by even the lowest amount of competitor. Similarly, the tRNA$^{\text{phe}}$ competitor specifically inhibited export of Xenopus SRP RNA as well as of tRNA$^{\text{phe}}$ itself (Fig. 2B). However, export inhibition by the tRNA competitor was not as effective as that by the pre-miRNA competitor. In contrast, the U1ΔSm competitor inhibited export of only...
U1ΔSm itself (Fig. 2C). These results strongly suggested that the primary candidate for the export receptor for vertebrate SRP RNA is Exportin-5, considering that pre-miRNA is exported by Exportin-5 and tRNA is exported by Exportin-5 or Exportin-t.

Figure 1 Nuclear export of SRP RNA is independent of CRM1. (A) A mixture of in vitro-transcribed 32P-labeled DHFR mRNA, Xenopus SRP RNA, U1ΔSm RNA, U6Δss RNA and tRNA phe was injected into the nucleus of Xenopus oocytes either with 0.2 μg/oocyte of BSA-NES (lanes 3 and 4) or with the same amount of BSA-mut (mutated NES, lanes 5 and 6). DHFR mRNA and U1ΔSm RNA were m7G-capped, and other RNAs were uncapped. RNA was analyzed immediately (0 h; lanes 1 and 2) or 1.5 h (1.5 h; lanes 3–6) after injection. N, nuclear; C, cytoplasmic fractions. (B) Quantitation of RNA export from four independent experiments as in A. (C) The same as A except that human SRP RNA instead of Xenopus SRP RNA was injected into the nucleus of oocytes either with 0.3 μg/oocyte of BSA-NES or with the same amount of BSA-mut. (D) Quantitation of RNA export from three independent experiments as in C.
Exportin-5 mediates export of vertebrate SRP RNAs

Consistent with the above results, microinjection of the recombinant human Exportin-5 in *Xenopus* oocytes stimulated export of microinjected *Xenopus* SRP RNA as well as of tRNA^phe^, but not of U1ΔSm RNA (Fig. 3A, lanes 2–5 and Fig. 3B), whereas microinjection of the recombinant human Exportin-t stimulated only tRNA^phe^ export (Fig. 3A, lanes 6 and 7 and Fig. 3B). Very similar results were obtained when human, instead of *Xenopus*, SRP RNA was used (Fig. 3C, D). These results suggested that vertebrate SRP RNA uses the Exportin-5-dependent export pathway.

To further confirm the above conclusion, a specific antibody raised against human Exportin-5 or a control antibody raised against hnRNP K was microinjected together with ^32^P-labeled RNAs. As expected, export of *Xenopus* SRP RNA as well as of tRNA^phe^ and pre-miR–31 was inhibited only by the anti-Exportin-5 antibody, whereas export of U1ΔSm was unaffected (Fig. 4A, B). Export inhibition of tRNA^phe^ and pre-miR–31 by the antibody was much weaker than that of SRP RNA. This was because export of tRNA^phe^ and pre-miR–31 is kinetically much faster than that of SRP RNA. The same antibody but not the control antibody also inhibited export of human SRP RNA (Fig. 4C, D). In the latter experiment, we used longer incubation time (1.5 h) as export kinetics of human SRP RNA is slower than that of the *Xenopus* counterpart. Under these conditions, therefore, export of tRNA^phe^ was apparently unaffected by the antibody, because of the fast export kinetics. Nevertheless, these results, taken together, strongly suggested that Exportin-5 is the export receptor for vertebrate SRP RNA.
Exportin-5 interacts with SRP RNA

The results so far prompted us to test whether Exportin-5 can interact with vertebrate SRP RNA. This interaction could be indirect, that is, adaptor-mediated, we first tested whether Exportin-5 could be pulled down from HeLa cell nuclear extracts (HNE) together with exogenously added human SRP RNA. In vitro-transcribed biotinylated human SRP RNA was incubated with HNE in the presence or absence of recombinant RanQ69LGTP, a constitutively active mutant form of Ran loaded with GTP, the RNA was then pulled down with streptavidin beads, and the precipitated protein was analyzed by Western blotting (Fig. 5). Exportin-5 was only weakly pulled down by human SRP RNA alone (Fig. 5A, lane 1) or with 150 fmol/oocyte of Exportin-5 (lanes 4 and 5) or Exportin-t (lanes 6 and 7). RNA was analyzed immediately (lane 1) or 15 min (lanes 2–7) after injection. In contrast, CRM1 was not pulled down under the same conditions. To further confirm the specificity of the interaction between Exportin-5 and human SRP RNA, cross-competition experiments were carried out (Fig. 5B). Addition of increasing amounts of nonbiotinylated VA1 RNA as well as nonbiotinylated human SRP

Figure 3 Exportin-5 mediates nuclear export of SRP RNA. (A) A mixture of 32P-labeled Xenopus SRP RNA, U1ΔSm RNA, U6Δss RNA and tRNAphe was injected into the nucleus of oocytes either alone (lanes 2 and 3) or with 150 fmol/oocyte of Exportin-5 (lanes 4 and 5) or Exportin-t (lanes 6 and 7). RNA was analyzed immediately (lane 1) or 15 min (lanes 2–7) after injection. (B) Quantitation of RNA export from the six independent experiments as in A. (C) A mixture of 32P-labeled DHFR mRNA, human SRP RNA, U1ΔSm RNA, U6Δss RNA and tRNAphe was injected either alone (lanes 2 and 3) or with 60 fmol/oocyte of Exportin-5 (lanes 4 and 5) or Exportin-t (lanes 6 and 7). RNA was analyzed immediately (lane 1) or 40 min (lanes 2–7) after injection. (D) Quantitation of RNA export from the three independent experiments in C.
RNA itself could competitively inhibit the interaction between Exportin-5 and biotinylated human SRP RNA (Fig. 5B, lanes 3-9), whereas nonbiotinylated U1ΔSm had no effect. These results are consistent with the idea that human SRP RNA is one of the specific export substrates for Exportin-5.

As exogenously added SRP RNA could associate with SRP proteins as showed by the Western blotting with the anti-SRP14 antibody (Fig. 5A), it was possible that an adaptor protein(s) in HNE bridged the interaction between Exportin-5 and SRP RNA. To test this possibility, we next examined the direct interaction between recombinant Exportin-5 and SRP RNA (Fig. 5C). Biotinylated SRP RNA could pull down recombinant Exportin-5 only weakly, but this interaction was greatly stimulated by the presence of RanQ69L-GTP (Fig. 5C, lanes 7, 8). These results indicated that Exportin-5 can directly recognize human SRP RNA.

**Discussion**

In this report, we have provided several lines of evidence suggesting that Exportin-5 is the principal...
nuclear export receptor for SRP RNA in vertebrates, unlike in the budding yeast in which CRM1 plays an important role. Two major questions arise: How Exportin-5 recognizes vertebrate SRP RNA and why the export pathway differs between vertebrates and the budding yeast?

Recognition of vertebrate SRP RNA by Exportin-5

Exportin-5 mediates nuclear export of many uncapped structured RNA species including pre-miRNA, tRNA, large rRNA and adenovirus VA1 RNA (Gwizdek et al. 2001, 2003; Bohnsack et al. 2002, 2004; Calado et al. 2002; Yi et al. 2003; Lund et al. 2004; Wild et al. 2010). Exportin-5 directly recognizes the structure of double-stranded (ds) RNA with 3′ overhang in a Ran-GTP dependent manner. An atomic structure analysis of the Exportin-5, pre-miRNA and RanGTP complex showed that the overall structure resembles a baseball mitt and that the mitt accommodates the dsRNA stem structure of pre-miRNA (Okada et al. 2009). In addition, a tunnel-like structure at the bottom of the mitt recognizes the RNA’s 3′ end protruding from the stem.

Previous structural studies suggested that the 3′-end of the vertebrate SRP RNA is located at the end of helix 5, which forms the linker region and a
portion of Alu and S domains, and is protruding from the helix (Halic et al. 2004). Therefore, we propose a model in which helix 5 and the 3′ overhang are directly recognized by Exportin-5. However, it is still possible that bound protein factors influence the interaction between Exportin-5 and SRP RNA, for instance, by keeping the proper RNA secondary structure that enables more efficient Exportin-5 association or by sterically inhibiting the access of the export receptor.

**Difference between yeast and vertebrate in SRP RNA export**

What is the reason why yeast SRP RNA does not use the Exportin–5 (Msn5p in yeasts) export pathway? There are several differences in the structure of SRP RNA between vertebrates and the budding yeast (Zwieb et al. 2005; Andersen et al. 2006; Rosenblad et al. 2009). Most importantly, the structure near the 3′-end is quite different. In the case of the budding yeast SRP RNA, four extra helices (helix 9–12) are inserted into helix 5 (Fig. S1 in Supporting Information). Therefore, we speculate that Exportin–5 cannot recognize the 3′-end of yeast SRP RNA due to the steric hindrance. Consistent with this idea, yeast SRP RNA was hardly exported in Xenopus oocytes and became unstable upon longer incubations (Fig. S2 in Supporting Information), suggesting that Exportin–5 cannot efficiently function for yeast SRP RNA as an export receptor.

Moreover, the protein components of SRP are somewhat different between the two species. Yeast SRP similarly contains six protein components, Srp21, 14, 54, 68, 72 and Sec65, in which Srp21 and Sec65 are homologues of vertebrate SRP9 and 19, respectively (Hann & Walter 1991; Stirling & Hewitt 1992; Brown et al. 1994; Mason et al. 2000; Rosenblad et al. 2004). However, vertebrate SRP9 forms a heterodimer with SRP14, whereas yeast counterpart (Srp21) does not. Instead, yeast Srp14 forms a homodimer (Strub et al. 1999; Mason et al. 2000). These differences in the protein composition may affect the recognition by the export receptors in both negative and positive ways. There has been no evidence that CRM1 can directly recognize RNA. Therefore, it is plausible to assume that one of the yeast Srp proteins or other SRP-associating protein(s) has an NES-like sequence and serves as an adaptor between yeast CRM1 and yeast SRP RNA.

**Experimental procedures**

**DNA constructs, templates for in vitro transcription and antibodies**

For preparation of the plasmid encoding Xenopus laevis SRP RNA, a DNA fragment containing the sequence of Xenopus laevis SRP RNA and EcoRI, DhaI, and SgfI sites was generated by RT-PCR using RNA from Xenopus laevis oocytes and the following primers: 5′-AAAGATTCATGGCTGCTTGTCCGGG-3′ and 5′-AAATCTAGACTCGAGTTTGG-3′, and then the amplified fragment was inserted into the EcoRI-SgfI sites of pSp65. Cloning of human SRP RNA was similarly carried out using RNA from HeLa cells and specific primers: 5′-AAAGAATTCATGACTCTGATATAGGCTGCTTGTCCGG-3′ and 5′-AAATCTAGACTCGGTTTGG-3′. For preparation of the plasmid encoding VA1 RNA, a DNA fragment corresponding to the sequence of VA1 RNA was generated by PCR using Adeno–X System 1 Viral DNA (Clontech) and the specific primers: 5′-AAATCTAGACTGATATAGGCTGCTTGTCCGG-3′ and 5′-AAATCTAGACTGATATAGGCTGCTTGTCCGGG-3′, and then the amplified fragment was inserted into the XbaI-PstI sites of pUC118. A DNA fragment containing the T7 promoter–VA1 RNA was generated by PCR using the pUC118-VA1 plasmid and specific primers: 5′-AAAGAATTCATGACTCTGATATAGGCTGCTTGTCCGGG-3′ and 5′-AAATCTAGACTGATATAGGCTGCTTGTCCGGG-3′, and then the fragment was inserted into the EcoRI-SgfI sites of pSp65.

The pSp65-based plasmids for Xenopus SRP RNA and VA1 RNA were digested with DhaI for in vitro transcription, whereas the template for human SRP RNA was produced by PCR using the pSp65–human SRP RNA plasmid and the following primers: 5′-AAATCTAGACTCAGCTATGGCTGCTTGTCCGG-3′ and 5′-AAATCTAGACTGATATAGGCTGCTTGTCCGGG-3′. In vitro transcription of these templates would yield the precursor form containing UCUUUU 3′-end and the mature form containing UCU 3′-end for Xenopus and human SRP RNAs, respectively. The template for in vitro transcription of pre-miR-31 was generated as previously described (Lund et al. 2004).

For preparation of the plasmid encoding Saccharomyces cerevisiae SRP RNA, a DNA fragment containing the sequence of Saccharomyces cerevisiae SRP RNA was generated by PCR using DNA from Saccharomyces cerevisiae and the following primers: 5′-AAATCTAGACTCAGCTATGGCTGCTTGTCCGG-3′ and 5′-AAATCTAGACTGATATAGGCTGCTTGTCCGGG-3′. In vitro transcription of these templates would yield the precursor form containing UCUUUU 3′-end and the mature form containing UCU 3′-end for Xenopus and human SRP RNAs, respectively. The template for in vitro transcription of pre-miR-31 was generated as previously described (Lund et al. 2004).
The pQE60 plasmid for expressing His-tagged human Exportin-5 was kindly gifted from Dr. Jun Katahira (Shibata et al. 2006). For preparation of the plasmid for expressing His-tagged Exportin-t, a DNA fragment containing the Exportin-t coding sequence was generated by RT-PCR using RNA from HeLa cells and specific primers: 5'-AAACCATGGATG AACAGGCTCTAT-3' and 5'-TTCTATGATCATGGAAGT AGGCACAGG-3', and then PCR was carried out using the DNA fragment generated by RT-PCR and the following primers: 5'-AAACCATGGATGAACAGGCTCTAT-3' and 5'-AAAGGATCCGGGCTTTTGTCTCTGG-3'. The amplified product was inserted into the Ncol-BamHI sites of pQE60. Polyclonal antibodies against coilin, Exportin-5, and His tag were from BD (611833) and MBL (ab155004), respectively. Monoclonal antibodies against hnRNP K and SRP14 were from Santa Cruz (sc-32860), Sigma (SAB4200003), MBL (RN019P) and Abcam (ab155004), respectively. Monoclonal antibodies against CRM1 and His tag were from BD (611833) and MBL (D291-3), respectively.

Recombinant proteins

Expression and purification of His-tagged Exportin-5 and RanQ69LGTP were carried out as described previously (Ohno et al. 2000; Shibata et al. 2006). Expression and purification of His-tagged Exportin-t were carried out as His-tagged Exportin-5.

RNA-protein binding assay

Biotinylated human SRP RNA was synthesized using MEGAscript (Ambion) and Biotin-16-UTP (Roche). The competitor RNAs were also synthesized using MEGAscript. Biotinylated human SRP RNA was incubated with RanQ69LGTP and HeLa cell nuclear extracts, with or without the competitor RNAs in buffer A [20 mM Tris–HCl (pH 7.5), 100 mM KCl, 2.5 mM MgCl2, 20% glycerol, 0.5 mM DTT, 0.1% NP-40 and protease inhibitor cocktail, complete (Roche)] for 30 min at 30°C, and then the mixture was incubated with streptavidin-sepharose beads (GE Healthcare) for 1 h at 4°C. After the beads were washed four times with buffer A, the bound material was recovered with 1 × SDS sample buffer and analyzed by Western blotting. The pull-down assay using the recombinant Exportin-5 was similarly carried out.

Microinjection into Xenopus oocytes

Preparation of 32P-labeled RNAs and their microinjection into Xenopus oocytes were carried out as described previously (Masuyama et al. 2004). Preparation of BSA-NES and BSA-mut was as described previously (Masuyama et al. 2004).

Acknowledgements

We thank Dr Jun Katahira for the pQE60 plasmid for expressing His-tagged human Exportin-5. This work was supported by a Grant-in-Aid for Scientific Research on Innovative Areas ‘Neo-taxonomy of noncoding RNAs’ (No. 26113004 to M.O.) from the Ministry of Education, Culture, Sports, Science and Technology (MEXT) of Japan.
