BALAYAGE AND SHORT TIME FOURIER TRANSFORM FRAMES

ENRICO AU-YEUNG AND JOHN J. BENEDETTO

Abstract. Using his formulation of the potential theoretic notion of balayage and his deep results about this idea, Beurling gave sufficient conditions for Fourier frames in terms of balayage. The analysis makes use of spectral synthesis, due to Wiener and Beurling, as well as properties of strict multiplicity, whose origins go back to Riemann. In this setting and with this technology, we formulate and prove non-uniform sampling formulas in the context of the short time Fourier transform (STFT).

1. Introduction

1.1. Background and theme. Frames provide a natural tool for dealing with signal reconstruction in the presence of noise in the setting of overcomplete sets of atoms, and with the goals of numerical stability and robust signal representation. Fourier frames were originally studied in the context of non-harmonic Fourier series by Duffin and Schaeffer [11], with a history going back to Paley and Wiener [26] (1934) and farther, and with significant activity in the 1930s and 1940s, e.g., see [24]. Since [11], there have been significant contributions by Beurling (unpublished 1959-1960 lectures), [9], [8], Beurling and Malliavin [7], [10], Kahane [21], Landau [23], Jaffard [20], and Seip [27], [25].

Definition 1.1. (Frame) Let $H$ be a separable Hilbert space. A sequence $\{x_n\}_{n \in \mathbb{Z}} \subseteq H$ is a frame for $H$ if there are positive constants $A$ and $B$ such that

$$\forall f \in H, \quad A\|f\|^2 \leq \sum_{n \in \mathbb{Z}} |(f, x_n)|^2 \leq B\|f\|^2.$$ 

The constants $A$ and $B$ are lower and upper frame bounds, respectively.

Our overall goal is to formulate a general theory of Fourier frames and non-uniform sampling formulas parametrized by the space $M_b(\mathbb{R}^d)$ of bounded Radon measures, see [4]. This formulation provides a natural way to generalize non-uniform sampling to the setting of short time Fourier transforms (STFTs) [18], Gabor theory [17], [13], [22], and pseudo-differential operators [18], [19]. The techniques are based on Beurling’s methods from 1959-1960, [8], [9], which incorporate balayage, spectral synthesis, and strict multiplicity. In this short paper, we show how to achieve this goal for STFTs.

1.2. Definitions. We define the Fourier transform $F(f)$ of $f \in L^2(\mathbb{R}^d)$ and its inverse Fourier transform $F^{-1}(f)$ by

$$F(f)(\gamma) = \hat{f}(\gamma) = \int_{\mathbb{R}^d} f(x)e^{-2\pi ix \cdot \gamma} \, dx,$$

and

$$F^{-1}(\hat{f})(\gamma) = f(x) = \int_{\mathbb{R}^d} \hat{f}(\gamma)e^{2\pi ix \cdot \gamma} \, d\gamma.$$

$\mathbb{R}^d$ denotes $\mathbb{R}^d$ considered as the spectral domain. We write $F^\vee(x) = \int_{\mathbb{R}^d} F(\gamma)e^{2\pi ix \cdot \gamma} \, d\gamma$. The notation “$\int$” designates integration over $\mathbb{R}^d$ or $\mathbb{R}^d$. When $f$ is a bounded continuous function,
its Fourier transform is defined in the sense of distributions. If $X \subseteq \mathbb{R}^d$, where $X$ is closed, then $M_b(X)$ is the space of bounded Radon measures $\mu$ with the support of $\mu$ contained in $X$. $C_b(\mathbb{R}^d)$ denotes the space of complex-valued bounded continuous functions on $\mathbb{R}^d$.

**Definition 1.2.** (Fourier frame) Let $E \subseteq \mathbb{R}^d$ be a sequence and let $\Lambda \subseteq \hat{\mathbb{R}}^d$ be a compact set. Notationally, let $e_x(\gamma) = e^{2\pi i x \cdot \gamma}$. The sequence $\mathcal{E}(E) = \{e_x : x \in E\}$ is a Fourier frame for $L^2(\Lambda)$ if there are positive constants $A$ and $B$ such that

$$\forall F \in L^2(\Lambda), \quad A\|F\|_{L^2(\Lambda)}^2 \leq \sum_{x \in E} |\langle F, e_x \rangle|^2 \leq B\|F\|_{L^2(\Lambda)}^2.$$ 

Define the Paley-Wiener space,

$$PW_\Lambda = \{f \in L^2(\mathbb{R}^d) : \text{supp}(\hat{f}) \subseteq \Lambda\}.$$ 

Clearly, $\mathcal{E}(E)$ is a Fourier frame for $L^2(\Lambda)$ if and only if the sequence,

$$\{(e_x 1_\Lambda)^\vee : x \in E\} \subseteq PW_\Lambda,$$ 

is a frame for $PW_\Lambda$, in which case it is called a Fourier frame for $PW_\Lambda$. Note that $\langle F, e_x \rangle = f(x)$ for $f \in PW_\Lambda$, where $\hat{f} = F \in L^2(\hat{\mathbb{R}}^d)$ can be considered an element of $L^2(\Lambda)$.

Beurling introduced the following definition in his 1959-1960 lectures.

**Definition 1.3.** (Balayage) Let $E \subseteq \mathbb{R}^d$ and $\Lambda \subseteq \hat{\mathbb{R}}^d$ be closed sets. Balayage is possible for $(E, \Lambda) \subseteq \mathbb{R}^d \times \hat{\mathbb{R}}^d$ if

$$\forall \mu \in M_b(\mathbb{R}^d), \quad \exists \nu \in M_b(E) \text{ such that } \hat{\mu} = \hat{\nu} \text{ on } \Lambda.$$ 

Balayage originated in potential theory, where it was introduced by Christoffel (early 1870s) and by Poincaré (1890). Kahane formulated balayage for the harmonic analysis of restriction algebras. The set, $\Lambda$, of group characters (in this case $\mathbb{R}^d$) is the analogue of the original role of $\Lambda$ in balayage as a set of potential theoretic kernels.

Let $\mathcal{C}(\Lambda) = \{f \in C_b(\mathbb{R}^d) : \text{supp}(\hat{f}) \subseteq \Lambda\}$.

**Definition 1.4.** (Spectral synthesis) A closed set $\Lambda \subseteq \hat{\mathbb{R}}^d$ is a set of spectral synthesis (S-set) if

$$\forall f \in \mathcal{C}(\Lambda) \text{ and } \forall \mu \in M_b(\mathbb{R}^d), \quad \hat{\mu} = 0 \text{ on } \Lambda \Rightarrow \int f \, d\mu = 0,$$ 

see [3].

Closely related to spectral synthesis is the ideal structure of $L^1$, which can be thought of as the Nullstellensatz of harmonic analysis. As examples of sets of spectral synthesis, polyhedra are S-sets, and the middle-third Cantor set is an S-set which contains non-S-sets. Laurent Schwartz (1947) showed that $S^2 \subseteq \hat{\mathbb{R}}^3$ is not an S-set; and, more generally, Malliavin (1959) proved that every non-discrete locally compact abelian group contains non-S sets. See [3] for a unified treatment of this material.

**Definition 1.5.** (Strict multiplicity) A closed set $\Gamma \subseteq \hat{\mathbb{R}}^d$ is a set of strict multiplicity if

$$\exists \mu \in M_b(\Gamma) \setminus \{0\} \text{ such that } \lim_{\|x\| \to \infty} |\mu^\vee(x)| = 0.$$
The notion of strict multiplicity was motivated by Riemann’s study of sets of uniqueness for trigonometric series. Menchov (1906) showed that there exists a closed set \( \Gamma \subseteq \mathbb{R}/\mathbb{Z} \) and \( \mu \in M(\Gamma) \setminus \{0\} \), such that \( |\Gamma| = 0 \) and \( \mu(n) = O((\log |n|)^{-1/2}) \), \( |n| \to \infty \). There have been intricate refinements of Menchov’s result by Bary (1927), Littlewood (1936), Beurling, et al., see [3].

The above concepts are used in the deep proof of the following theorem.

**Theorem 1.6.** Assume that \( \Lambda \) is an \( S \)-set of strict multiplicity, and that balayage is possible for \((E,\Lambda)\). Let \( \Lambda_\epsilon = \{ \gamma \in \hat{\mathbb{R}}^d : \text{dist}(\gamma, \Lambda) \leq \epsilon \} \). There is \( \epsilon_0 > 0 \) such that if \( 0 < \epsilon < \epsilon_0 \), then balayage is possible for \((E,\Lambda_\epsilon)\).

**Definition 1.7.** A sequence \( E \subseteq \mathbb{R}^d \) is separated if

\[ \exists r > 0 \text{ such that } \inf\{\|x-y\| : x, y \in E \text{ and } x \neq y\} \geq r. \]

The following theorem, due to Beurling, gives a sufficient condition for Fourier frames in terms of balayage. Its history and structure are analyzed in [4] as part of a more general program. Theorem 2.2 is used in its proof.

**Theorem 1.8.** Assume that \( \Lambda \subseteq \hat{\mathbb{R}}^d \) is an \( S \)-set of strict multiplicity and that \( E \subseteq \mathbb{R}^d \) is a separated sequence. If balayage is possible for \((E,\Lambda)\), then \( \mathcal{E}(E) \) is a Fourier frame for \( L^2(\Lambda) \), i.e., \( \{(e_{x} 1_{\Lambda})^\vee : x \in E\} \) is a Fourier frame for \( PW_\Lambda \).

See [23], [5], [2] (SampTA 1999), and [6].

2. Short time Fourier transform (STFT) frame inequalities

**Definition 2.1.** Let \( f, g \in L^2(\mathbb{R}^d) \). The short time Fourier transform (STFT) of \( f \) with respect to \( g \) is the function \( V_g f \) on \( \mathbb{R}^{2d} \) defined as

\[ V_g f(x, \omega) = \int f(t)g(t-x) e^{-2\pi i t \cdot \omega} \, dt, \]

see [18], [19] (chapter 8).

The STFT is uniformly continuous on \( \mathbb{R}^{2d} \). Further, for a fixed “window” \( g \in L^2(\mathbb{R}^d) \) with \( \|g\|_2 = 1 \), we can recover the original function \( f \in L^2(\mathbb{R}^d) \) from its STFT \( V_g f \) by means of the vector-valued integral inversion formula,

\[ f = \int \int V_g f(x, \omega) e_{\omega} \tau_x g \, d\omega \, dx, \]

where \( (\tau_x g)(t) = g(t-x) \).

**Theorem 2.2.** Let \( E = \{x_n\} \subseteq \mathbb{R}^d \) be a separated sequence, that is symmetric about \( 0 \in \mathbb{R}^d \); and let \( \Lambda \subseteq \mathbb{R}^d \) be an \( S \)-set of strict multiplicity that is compact, convex, and symmetric about \( 0 \in \hat{\mathbb{R}}^d \). Assume balayage is possible for \((E,\Lambda)\). Further, let \( g \in L^2(\mathbb{R}^d), \hat{g} = G, \) have the property that \( \|g\|_2 = 1 \).

a. We have that

\[ \exists A > 0, \text{ such that } \forall f \in PW_\Lambda \setminus \{0\}, \hat{f} = F, \]

\[ A\|f\|_2^2 \leq \sum_{x \in E} \int |V_G F(\omega, x)|^2 \, d\omega \]

\[ = \sum_{x \in E} \int |V_g f(x, \omega)|^2 \, d\omega. \]

b. Let \( G_0(\lambda) = 2^{d/4} e^{-\pi \|\lambda\|^2} \) so that \( \|G_0\|_2 = 1 \); and assume \( \|V_{G_0} G\|_1 < \infty \). We have that

\[ \exists B > 0, \text{ such that } \forall f \in PW_\Lambda \setminus \{0\}, \hat{f} = F, \]
\[ \sum_{x \in E} \int |V_g f(x, \omega)|^2 \, d\omega = \sum_{x \in E} \int |V_G F(\omega, -x)|^2 \, d\omega \leq B \|f\|_2^2, \]

where \( B \) can be taken as \( C \|V_G_0 G\|_1 \) and where
\[
C = \sup_{y, \gamma} \left\{ \sum_{x \in E} \int |V_G G_0(\gamma + \omega, y + x)| \, d\omega \right\}.
\]

The technique of using \( G_0 \) goes back to Feichtinger and Zimmermann [14] (Lemma 3.2.15) for a related type of problem, see also [13] (Lemma 3.2).

We next consider balayage being possible for \((E, \Lambda)\), where \( E = \{(s_m, t_n)\} \subseteq \mathbb{R}^{2d} \) and \( \Lambda \subseteq \mathbb{R}^{2d} \). This allows us to express the STFT \( V_g f \) of \( f \) as
\[
V_g f(y, \omega) = \sum_m \sum_n a_{mn}(y, \omega) h(s_m - y, t_n - \omega) V_g f(s_m, t_n),
\]
where
\[
\sum_m \sum_n |a_{mn}(y, \omega)| < \infty.
\]

The following result and others like it, including Theorem 2.2, can be formulated in terms of \((X, \mu)\) frames, [1], [16], [15].

**Theorem 2.3.** Assume balayage is possible for \((E, \Lambda)\), where \( E = \{(s_m, t_n)\} \subseteq \mathbb{R}^{2d} \) is separated, and \( \Lambda \subseteq \mathbb{R}^{2d} \) is an \( S \)-set that is compact, convex, and symmetric about \( 0 \in \mathbb{R}^{2d} \). Fix a window function \( g \in L^2(\mathbb{R}^d) \) such that \( \|g\|_2 = 1 \). There are constants \( A, B > 0 \), such that if \( f \in L^2(\mathbb{R}^d) \) satisfies the conditions,
1. \( V_g f \in L^1(\mathbb{R}^{2d}) \) and
2. \( F(V_g f)(\zeta_1, \zeta_2) \) has support \( \subseteq \Lambda \subseteq \mathbb{R}^{2d} \),

then
\[
A \int |f(x)|^2 \, dx \leq \sum_m \sum_n |V_g f(s_m, t_n)|^2 \leq B \int |f(x)|^2 \, dx.
\]

The hypothesis that \( V_g f \in L^1(\mathbb{R}^{2d}) \) means that \( f \) belongs to the Feichtinger algebra \( \mathcal{S}_0(\mathbb{R}^d) \). It is the smallest Banach space that is invariant under translations and modulations. There are other equivalent characterizations of \( \mathcal{S}_0(\mathbb{R}^d) \), see [12], [14]. Fix a function \( \mathcal{S}_0(\mathbb{R}^d) \) and define the vector space \( \mathcal{M}_1 \) of all non-uniform Gabor expansions
\[
f = \sum_{n=1}^{\infty} c_n \tau_{x_n} e_{\omega_n} g,
\]
where \( \{x_n, \omega_n\} \in \mathbb{R}^{2d}, n \in \mathbb{N} \) is an arbitrary countable set of numbers and \( \sum_{n=1}^{\infty} |c_n| < \infty \). For this space, the norm is taken to be \( \inf \sum_{n=1}^{\infty} |c_n| \), where the infimum is taken over all possible representations. Then the vector space \( \mathcal{M}_1 \) coincides with \( \mathcal{S}_0(\mathbb{R}^d) \). For functions in \( \mathcal{S}_0(\mathbb{R}^d) \), Theorem 2.3 should be compared to the following theorem of Gröchenig [17], [18] (Chapter 12):

**Theorem 2.4.** Given any \( g \in \mathcal{S}_0(\mathbb{R}^d) \). There is \( r = r(g) > 0 \) such that if \( E = \{(s_n, \sigma_n)\} \subseteq \mathbb{R}^d \times \mathbb{R}^d \) is a separated sequence with the property that
\[
\bigcup_{n=1}^{\infty} B((s_n, \sigma_n), r(g)) = \mathbb{R}^d \times \mathbb{R}^d,
\]
then the frame operator, $S = S_{g,E}$, defined by

$$S_{g,E} f = \sum_{n=1}^{\infty} \langle f, \tau_{s_n e_{\sigma_n}} g \rangle \tau_{s_n e_{\sigma_n}} g,$$

is invertible on $S_0(\mathbb{R}^d)$.

Moreover, every $f \in S_0(\mathbb{R}^d)$ has a non-uniform Gabor expansion,

$$f = \sum_{n=1}^{\infty} \langle f, \tau_{x_n e_{\omega_n}} g \rangle S_{g,E}^{-1}(\tau_{x_n e_{\omega_n}} g),$$

where the series converges unconditionally in $S_0(\mathbb{R}^d)$. ($E$ depends on $g$.)

A critical, thorough comparison of Theorems II.3 and II.4 is given in [4].
