Citic acid Mediated One-pot Regioselective Synthesis of N-Alkylated Indazoles: An Efficient Green Strategy

Abstract
Citic acid mediated green synthetic route has been demonstrated for the regioselective synthesis of N-alkylated indazoles in good to excellent isolated yields (~78-96%) from readily available starting materials 2-methylanilines (1), NaNO₂ (2) and ethyl chloroacetate (3) via diazotization, intra molecular cyclization and followed by N-alkylation in the presence of 1:1 ratio of ethanol and water in one-pot. Notably, if the substrate (1) contains –NO₂ group and is reduced to –NH₂ in the presence of Fe, CaCl₂ in the same pot at 60-65°C for 30-40 min. The remarkable advantages of this method include cleaner reaction profile, easy to perform, high yields of products and simple work-up procedure. Besides, the reaction is step-and atom-economic and is carried out in green catalytic medium.

Keywords: Citric acid; o-Toluidines; Ethyl chloroacetate; Regioselectivity; N-Alkylated Indazoles

Introduction
Heterocyclic ring systems are frequently found in numerous naturally occurring compounds and they compose the core structures of many biologically active motifs as well as some industrial compounds [1]. Among them, indazoles represent an important class of nitrogen containing heterocycles and this nucleus (Figure 1) [2,3] is of great current interest as partial structure in many synthetic drugs or drug candidates with a broad range of pharmacological activities including anti-HIV [4], anti-inflammatory [5], anti-tumor [6,7], anti-depressant [8], analgesic and antipyretic [9], anti-leukemia [10], anti-convulsant activity [11], anti-cancer [12], anti-arthritis [13], anthelmintic [14] and anti-diabetes [15]. Indazole moiety is present only in three natural products such as Nigellicine, Nigeglanine and Nigellidine indicates their rare presence in nature [16,17].

Extensive literature survey revealed that a huge number of methods have been reported for the synthesis of substituted 1H-indazoles. One general route involves diazotization of o-alkyl-substituted anilines followed by acid promoted cyclization [18,19], functionalized sydnone, oxadiazole condensation/Boulton-Katritzky rearrangement [20], intramolecular dehydration from common arylamino oximes/o-aminoenzoioximes [21,22], condensation of aryynes with nitrile imines/diazomethane derivatives/diazo compounds/hydrazones [23,24], condensation of hydrazine to o-halo/o-alkoxy arylhydrazones [25,26]. In addition to the above methods, other intra molecular cyclizations are also reported for the synthesis of indazole derivatives, for example Pd-mediated ring closure of hydrazine and hydrazone based derivatives [27,28], copper catalyzed intramolecular amination of o-haloarylcarbonyl compounds/2-haloarylhydrazides [29,30], Cul promoted cyclization of an aryl hydrazone under microwave irradiation [31], iron mediated intramolecular C-H amination of arylhydrazones [32], PIFA-mediated oxidative cyclization of o-aminobenzenilides [33], Rhodium-catalyzed cyclocarbonylation of azobenzenes [34], Zinc catalyzed reductive cyclization of o-nitrobenzenilides [35], layered Zirconium sulfophenyl phosphonate catalyzed synthesis from condensation of 1,3-diones and hydrazines under solvent free conditions [36] have been reported.

However, all the above methods are highly promising, but, most of them suffer from one or more disadvantages including the use of i) acids or reagents that are not environmentally compatible and corrosive, ii) hazardous starting materials, iii) metal catalysts.
and solvent(s), iv) long reaction time, v) cumbersome workup procedures and vi) production of a large amount of waste. In view of the importance of indazoles and the limitations of previous methods, the development of one-pot synthesis of indazoles from readily available starting materials in green catalytic medium would be of prime synthetic value. On the path of finding suitable one-pot green approach, our attention is directed towards classical diazotization and intramolecular cyclization in the presence of AcOH [37]. Prompted by this idea, biodegradable citric acid medium has been identified for the synthesis of N-alkylated 1H-indazoles in a single step operation. Citric acid is the non-toxic, low-cost, biodegradable and environmentally benign catalyst which is also employed in many organic transformations [38-41].

In this work, we demonstrated a biodegradable citric acid mediated green synthetic route for the regioselective synthesis of N-alkylated indazoles in good to excellent isolated yields (~ 78-96%) from readily available starting materials 2-methylanilines (1), NaNO2 (2) and ethyl chloroacetate (3) via diazotization, intramolecular cyclization and followed by N-alkylation in the presence of 1:1 ratio of ethanol and water in a single step operation. If the substrate (1) contains – NO2 group and is reduced to – NH₂ in the presence of Fe, CaCl₂ at 60-65°C (Chandrappa, Vinaya, Ramakrishnappa, & Rangappa, 2010) in the same step as shown in Figure 2.

Materials and Methods

1H NMR spectra are recorded on a Varian 300 MHz. Chemical shifts are expressed in parts per million (ppm), coupling constants are expressed in Hertz (Hz). Splitting patterns describe apparent multiplicities and are designated as s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet). Mass spectra (MS) are acquired on a Waters LCT premier XE TOF with electron spray ionization (ESI) source. Thin-layer chromatography is performed on 0.25 mm Merck silica gel plates and visualized with UV light. Column chromatography is performed on silica gel. Chemicals are purchased from Sigma Aldrich and Acros organics. Solvents are purchased from Merck. Millipore deionized water is used. Isolated compounds are identified on the basis of spectroscopic data and Mass spectrometry.

General experimental procedure for (substrates without – NO₂ functional group) the regioselective synthesis of ethyl 2-(1H-indazol-1-yl)acetate (4a): In a 100 mL three necked round bottom flask, 2-methylaniline (1a) (10 mmol) and citric acid (20 mmol) are dissolved in a mixture of ethanol (8 mL) and water (4 mL). The clear solution was cooled at 0-5°C and stirred well. To this added ice-cold solution of NaNO₂ (2) (12 mmol) in 4 mL of water in 4 portions for 5-10 minutes. The formation of 1H-indazole was monitored by TLC. After the completion of the reaction as per TLC, ethyl chloroacetate (3) (12 mmol) is added to the reaction mixture and is stirred under reflux conditions for 60 min. The progress of the reaction is monitored by TLC. After completion of the reaction, the reaction mixture is quenched in ice and the crude product is extracted twice with ethyl acetate (2 × 10 mL). The organic layer is washed with brine, dried over MgSO₄ and concentrated. The obtained crude product (4a) is purified by silica gel using n-hexane and EtOAc (3:1 ratio). The same procedure is followed for the preparation of compounds 4b-e. The synthesized compounds (4a-e) gave satisfactory spectroscopic data in accordance with their proposed structures. General experimental procedure for the (substrates with – NO₂ functional group) regioselective synthesis of ethyl 2-(5-amino-1H-
indazol-1-yl)acetate (4f): In a 100 mL three necked round bottom flask, 2-methyl-4-nitroaniline (1f) (10 mmol) and citric acid (20 mmol) are dissolved in a mixture of ethanol (8 mL) and water (4 mL). The clear solution is cooled at 0-5°C and stirred well. To this added ice-cold solution of NaN₂O₂ (2) (12 mmol) in 4 mL of water in 4 portions for 5-10 minutes. The formation of 1H-indazole is monitored by TLC. After the completion of the reaction as per TLC, ethyl chloroacetate (3) (12.0 mmol) is added to the reaction mixture and is stirred under reflux conditions for 60 min. The progress of the reaction is monitored by TLC. After completion of the reaction as per TLC, reaction mixture is filtered to remove the iron residue and washed with EtOAc (2 × 10 mL). The organic layer is washed with water, dried over MgSO₄ and concentrated. The obtained crude product (4f) is purified by silica gel using n-hexane and EtOAc (3:1 ratio). The same procedure is followed for the preparation of compounds 4g–j. The synthesized compounds (4f–j) gave satisfactory spectroscopic data in accordance with their proposed structures.

Results and Discussion

In the present study, our initial efforts are focused on identifying the catalyst, solvent(s) for the construction of 1H-indazole followed by N-alkylation in a single step operation. For this purpose, the reaction of 2-methyl anilines (1a) with NaN₂O₂ (2) and followed by treatment with ethyl chloroacetate (3) in one-pot was chosen as a model reaction to optimize the reaction conditions and the obtained results are presented in Table 1. The construction of 1H-indazole followed by N-alkylation involved in the present process which is carried out in the presence of various biodegradable α-hydroxy acidic catalysts such as malic acid, mandelic acid, tartaric acid and citric acid (1.0 equivalent) in water for about 150 min. Low yields of product 4a, 5%, 5%, 8% and 15%, are obtained respectively. To improve the yield, the same reaction is repeated by employing various solvents, like methanol, isopropanol, EtOH, EtOH:H₂O (1:1 ratio), EtOH:H₂O (2:1 ratio) and EtOH:H₂O (3:1 ratio) and the results are presented in Table 1. After the examination of various α-hydroxy acid catalysts and solvents, it is found that citric acid (1.0 eq) and 1:1 ratio of EtOH:H₂O medium is the best option to obtain good yield (75%) of the product (4a) and other α-hydroxy acid catalysts and solvents give low yields of product (4a).

Effect of mode of addition of NaNO₂

It is interesting to mention the effect of mode of NaNO₂ addition. It is investigated and found that the portion wise addition and one time addition of NaNO₂ had a significant effect on the isolated yield of the desired product (4a). For example, the isolated yield of the product (4a) is increased on addition of NaNO₂ in portion wise (entries 2-4, Table 2) when compared to one-time addition of NaNO₂ (entry 1, Table 2). The review concluded that addition of NaNO₂ in 4 portions provided improved yield of product 4a (entry 4).

Further, it is noteworthy to mention that the substrate (1) contains – NO₂ group and is reduced to – NH₂ in the presence of Fe, CaCl₂ at 60-65°C for 30-40 min in the same pot. This functional group transformation is useful for the development of indazole based new chemical entities of potential pharmacological interest.

Scope of the method

With the help of the above optimized reaction conditions, the scope of the present method is studied using different types of substituted 2-methyl anilines (1a–j) and the obtained results are presented in Table 3. The 2-methyl aniline (1a) provided excellent yields of desired product (4a) i.e. 96% (entry 1, Table 3). The substrates (1d) and (1c) bearing chloro group at 4- and 5- positions, afforded excellent yield of products 4c (94%) and 4d (94%) when compared to the same substituent at 2- and 6-positions of the substrates (1b) and (1e) (entries 2-5, Table 3). This may be due to the ortho effect. Substrate (1g) with -NO₂ group at 5-position, afforded good yields of product (4g) when compared to the same substituent at 4- and 6-positions of the substrates (1f) and (1h) (entries 6-8, Table 3). The main reason is that the -NO₂ group in (1f) and (1h) is suitably located for withdrawing of electrons strongly from NH₂ group whereas this type of situation is not observed in the case of (1g). Substrates (1i) and (1j) containing both nitro (– NO₂) and chloro (– Cl) groups provided lower yields of products 4i (80%) and 4j (78%) compared to the mono substituted substrates (entries 9 and 10, Table 3). This may be attributed to the steric effects. From the above study, it is found that the substrates bearing weak electron-withdrawing substituents (i.e. chloro) (1b-e) provided excellent isolated yields of desired products in the range of 90-94% (entries 2-5, Table 3) when compared to the substrates with strong electron-withdrawing substituents (i.e. nitro) (1f-h) (84-92% yields) (entries 6-8, Table 3).

Physical and spectral data of the synthesized compounds

1. Ethyl 2-(1H-indazol-1-yl)acetate (4a): Colourless oil, Yield=96%, 1H NMR (300 MHz): δ 8.25 (d, J=7.2 Hz, 1H, arom H), δ 8.0 (s, 1H, arom H), 7.80 (d, J=7.2 Hz, 1H, arom H), 7.50-7.42 (m, 2H, arom H), 7.34-7.32 (m, 1H, arom H), 5.2 (s, 2H, -N-CH₂-), 4.22 (q, J=6.9Hz, 2H, -OCH₂-), 1.24 (t, J=6.9Hz, 3H, CH₃). MS (ESI): m/z [M+Na]+ 227.44.
2. Ethyl 2-(4-chloro-1H-indazol-1-yl)acetate (4b): Colourless oil, Yield=90%, 1H NMR (300 MHz): δ 8.07 (s, 1H, arom H), 7.65 (d, J=7.2Hz, 1H, arom H), 7.36 (d, J=7.2Hz, 1H, arom H), 7.10 (t, J=7.2Hz, 1H, arom H), 5.54 (s, 2H, -N-CH₂-C=O), 4.23 (q, J=6.6Hz, 2H, -OCH₂-), 1.26 (t, J=6.6Hz, 3H, CH₃). MS (ESI): m/z [M+H+35Cl]+ 239.26; [M+H+37Cl]+ 241.28.
3. Ethyl 2-(5-chloro-1H-indazol-1-yl)acetate (4c): Colourless oil, Yield=94%, 1H NMR (300 MHz): δ 8.05 (s, 1H, arom H), 7.72 (d, J=2.4Hz, 1H, arom H), 7.46 (d, J=6.6Hz, 1H, arom H), 5.14 (s, 2H, -N-CH₂-C=O), 4.23 (q, J=6.9Hz, 2H, -OCH₂-), 1.27 (t, J=6.9Hz, 3H, CH₃). MS (ESI): m/z [M+H+35Cl]+ 239.26; [M+H+37Cl]+ 241.36.
4. Ethyl 2-(6-chloro-1H-indazol-1-yl)acetate (4d): Colourless oil, Yield=94%, 1H NMR (300 MHz): δ 8.04 (s, 1H, arom H), 7.68 (d, J=7.2Hz, 1H, arom H), 7.37 (s, 1H, arom H), 7.16 (d, J=7.2Hz, 1H, arom H), 5.12 (s, 1H, arom H), 4.24

*aReaction conditions: 2-methyl aniline (1a) (10 mmol), NaNO₂ (2) (12 mmol), (portion wise) citric acid (15 mmol), ethyl chloroacetate (3) (10 mmol) in a mixture of Ethanol:H₂O (1:1 ratio). *bIsolated yield.
A practical and green synthetic route has been developed for the regioselective synthesis of N-alkylated indazoles in one-pot from readily available starting materials 2-methylanilines (1), NaNO₂ (2) and ethyl chloroacetate (3) via diazotization, intra molecular cyclization and followed by N-alkylation in the presence of citric acid in a mixture of ethanol and water (1:1 ratio). Notably, if the substrate (1) contains – NO₂ group and the reduction in the presence of Fe, CaCl₂ in the same pot at 65°C. The superior features of the present method comprise of broad substrate scope, cleaner reaction profile, easy to perform, high yields of products and simple work-up procedure. Besides, the reaction is step-and atom-economic.
and is carried out in green catalytic medium. Thus, the method meets with the concepts of Wender’s “ideal synthesis”. Hence,
